I have not read the papers of Dr. Stone to which he refers, but if he will accept a suggestion from me, I think I can put him in the way to do what he wishes. Let him use flat electrodes cased in cloth, so as to prevent actual contact with the skin, and put them in pans of salt water so that the hand or foot can be placed upon them; or the ordinary tubular conductors cased in thick cloth can be used. Then have a similar pair, placed in a pan of the liquid, and made part of the branch of the bridge which contains the resistance measure, using two equal resistances in the other branches, so as to have equal currents passing both pair of electrodes, and therefore equal polarisation effects. The resistance of this cell (which replaces the voltameter I first suggested above) can now be ignored, because it is closely equal to that of the connections to the body, and the observed resistance will be that of the

Digitized by Google

body itself free from secondary reactions. Even then I should look for different measures with constant and with alternating currents. But the measurement of this difference would in itself be interesting and valuable, for it would indicate something of the storage capacity of the body, as distinguished from its transmitting capacity, and so open a road to knowledge of the reasons why the alternating current has the greatest effect. On this head I may as well indicate another anomaly in the applications of Ohm's formulæ in these cases. If we found that the resistance as measured with alternating current is less than with the continuous, it would not follow that the current or the energy passed into the body is greater for an equal E.M.F. Two reasons would be against this :— 1. An alternating E.M.F. would not be active for the whole time. 2. The lower resistance would not be a real fact, but an erroneous deduction.—Yours, &c.,

JOHN T. SPRAGUE.

P.S.—It appears that I somewhat misunderstood Dr. Stone's intention as to his proposed liquid resistance. I see that he means to use it simply as one branch of the bridge, and as the total resistance balancing the man. At first reading I thought he meant to use the shifting electrode as the movable contact of a bridge. This, of course, modifies part of what I have said above. But still it is doubtful if the desired result will be attained, as the liquid resistance differs from a wire rheostat only at the electrodes, and therefore these ought to correspond completely with the conductors to the body. I have often employed liquid resistances just like the proposed one, but have found that every motion of the electrode produces a great disturbance in the balance. However, if Dr. Stone wishes to try it, I will describe the apparatus I have found most suitable.

Let two glass tubes be mounted vertically and close together on a stand, their upper ends being considerably enlarged, so as to contain a cylindrical electrode of large surface ; a syphon tube reaching to the bottom connects the liquids in the tubes, so that the current has to traverse the syphon, which is a fixed resistance, and the outer tubes, the resistance of which is variable by raising the syphon which is suspended from a counterpoise in front of a scale upon which the resistance in ohms corresponding is marked. I have also used two horizontal troughs side by side, built of strips of glass cemented together, and united by a movable syphon. The vertical plan enables the liquids to be covered with a layer of paraffin oil to prevent evaporation and the nuisance of creeping. I have usually employed sulphate of copper, reversing the current occasionally; but for the intended use in which the polarisation effect is desired, dilute salt water would be preferable. Such a liquid resistance measure is useful when an invariable resistance is required, because by combining with it a due proportion of metallic resistance we can compensate for variation of temperature.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : I am sorry to find that Dr. Stone considered the tone of my letter discourteous. I am unconscious of any intention to be so ; nor can I, on a careful perusal of my letter, find any expression that I should so interpret if applied to myself.

At the same time, I at once and freely tender my apology for any inadvertence that may have escaped me.

I certainly adhere to my opinion that it is a misfortune that more use was not made of the accident at "The Healtheries," and I would point to the fact that while Dr. Stone is continually asking for facts—even in the letter before me he hopes to obtain authentic *post mortem* records in a particular case—after six months the best that he can tell us of an accident that happened in the very building where he had been lecturing, and the subject of which was taken to a London hospital, is that he *believes* the *post mortem* will be published, urgent and repeated applications for information having meanwhile been ignored.

With regard to my use of the words "may" and "may not," I beg to say that I merely put forward ideas that occurred to me, in the hope that Dr. Stone and others who have a knowledge of the subject would take them up. I have studied the subject for many years, as carefully as time, opportunity, and my necessarily very imperfect knowledge of physiology would allow ; and I have naturally a deep interest in the endeavour to get over the difficulty of using high tension currents, seeing how great the advantages are for the distribution of light and power by means of electricity.

With regard to the question of the resistance of the human body *per se*, I maintain with all due deference to Dr. Stone, and without the slightest intention of discourtesy towards him, that it must be an immeasurable quantity, in the sense that no such thing as its absolute resistance can exist. He himself has shown that the measured resistance depends upon the size, nature, and condition of the electrodes.

On the other hand, a few measurements taken from hand to hand or from hand to feet, one hand having a cut or sore place, and in the case of the measurement from hand to feet the earth forming part of the circuit, would be of great value.

An amusing case came under my own notice which confirms, if confirmation is wanted, Dr. Stone's experience with the spark from his induction coil.

A workman was required to test a faulty battery. He had no galvanometer, and being on the top of one of the Welsh hills, he could not obtain one. He had, however, a sore thumb. He applied the thumb to each cell in succession, pronouncing those cells bad which failed to make him "jump." A subsequent test with a galvanometer confirmed his improvised bad thumb test. The old test of the tongue will naturally occur to everyone.

There is another important matter I wish to refer to. I understand Dr. Stone to hold that the resistance of the body, or any part of it *per se*, varies inversely with the E.M.F. of the testing current.

I have not the slightest wish to impugn Dr. Stone's measurements, upon which he appears to have spent a great deal of his valuable time and also large sums in procuring the most reliable instruments ; but, as I believe I am correct in stating that we have no other instance of a body changing its electrical resistance, unless it had previously been subjected to some other physical change, I would ask, have we any good reason for supposing that the human body is an exception to this rule, and if not, should not the cause of the change be sought ?

I have already suggested in another place that possibly what is measured as apparent resistance is really in part, as in other cases, an opposing E.M.F.

Mr. Sprague and Mr. Blakesley have each given other explanations which are of great interest, and will, I trust, be followed up. The source of the opposing E.M.F. I allude to may be the resultant products of electrolysis, and I have also suggested that it is due to the inductive action upon each other of the fluid conductors, which are each moving at a high speed in the magnetic field which the current in each creates around itself. The fact that the alternating current gives the lowest measured result appears to me to be a confirmation of this, inasmuch as it is well known that alternating currents from their nature create but feeble magnetic fields in comparison with continuous currents. Dr. Stone rather ridiculed my suggestion at the Healtheries, on the ground that he had laid his head between the poles of a powerful permanent magnet, capable of rotating a beam of light through several degrees, but it was unable to rotate him one degree.

Singularly enough, a partial confirmation of my views comes from abroad. I have not the copy of the *Journal of Science* by me in which it is referred to ; but I think it is a German physician who experimented with two similar incubators. One batch of eggs were set in the usual way, but in the other the eggs were exposed to the influence of permanent magnents placed in their neighbourhood. While a fair number of the eggs not exposed to the influence of the magnets produced strong healthy chickens, only a very few of those that were so exposed came to maturity, and of those the whole were irregular in some way or other, one paralysed, and so on. Evidently something had been going on within the eggs, and I suggest that very minute electric currents were generated, which prejudicially affected the embryo.

In looking through the *Journal* of the Society of Telegraph

Digitized by Google

Engineers, I notice two very important cases bearing upon the points under discussion.

One is the report of Mr. James Graves of the storm which passed over Valentia in July, 1878, in which several animals were killed, and a cottage wrecked, and in particular three cows were *so burnt that their flesh was quite black*, and the smell so offensive that the farmer could not even remove their hides.

The other is the case mentioned by Professor Adams, of the accident which happened to the engineer at the South Foreland. Evidently in this case the shock was produced by the *extra* current on breaking circuit, and though sufficiently severe to knock the man down, was of so short duration that he received no permanent injury. Comparing this case with that of the stoker on board the Czar's yacht, who, if the reports were correct, only received the E.M.F.. of one Jablochkoff candle, yet was killed, appears to me full of instruction.

I think that here at least we are quite in our infancy, and I repeat that our best thanks are due to Dr. Stone and others who have taken the matter up. If by their researches they can show us how to use high tension currents without danger, they will have conferred a great boon upon society, and will materially aid the advance of practical electrical work.—Yours, &c.,

SYDNEY F. WALKER.

DYNAMO CONSTRUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I presume that Mr. Pardoe* is the correspondent who previously signed himself "Volt-Ampere," and I am glad to find that my communication in your issue of the 17th inst. was of service to him. But the question now asked, "What E.M.F. will be generated by A at a given speed and with a given number of turns at a given *velocity?*" is scarcely intelligible. The total E.M.F. of any dynamo, self-exciting or otherwise, may be expressed by $E = K\,\omega\,\frac{W}{a}\,V$ where

E = E.M.F.
V = velocity.
W = weight of copper on armature in pounds.
a = sectional area of wire on armature in square mils.
ω = magnetic field in ampere turns.
K = a constant.
Also let L = length of wire on armature with the winding for E.
L_1 = length with winding for E_1.
C = current in amperes, with winding for E.
C_1 = current in amperes, with winding for E_1.
γ = number of turns on magnets.

Now, although it is not possible to know with any certainty what E may actually turn out to be in the first machine from such a condensed equation as the above, still it may be used with great advantage in practice. For suppose E_1 to be required from the same sized dynamo, then

$$E_1 = K\,\omega\,\frac{W}{a}V.$$

Divide the first equation by the second

$$\frac{E}{E_1} = \frac{a_1}{a} \text{ whence } E_1 = \frac{Ea}{a_1}$$

$$\text{But } a = \frac{d^2\pi}{4} \quad \therefore E_1 = \frac{Ed^2}{d_1^2} \quad \text{and} \quad d_1 = d\sqrt{\frac{E}{E_1}} \quad . \quad . \quad . \quad .$$

W lbs of wire, d mils in diameter, must then be wound on the armature.

We now come to the magnetic field, which is expressed in "ampere turns." The latter term may be defined as the product of the two factors, amperes and turns or convolutions around the iron cores. Whence $V = \frac{\omega}{C_1}$. The output of the machine in volt-amperes will be identical with the two windings, or $EC = E_1C_1$; whence $C_1 = \frac{EC}{E_1}$. Substitute for C_1 and we have $V = \frac{\omega E_1}{EC}$.

The diameter of this wire must, of course, be proportioned to carry the current C_1, and should be such that $d = 32\sqrt{C_1}$, as stated in my previous letter. I fear that Mr. Pardoe does not fully grasp the complex nature of dynamo machines, or he would know that it would require a far greater space than I dare trespass upon to set down my comprehensive formulæ, still more to attempt to explain them.

One caution would, perhaps, not be out of place. Do not try to make very small dynamos, for they will not work, the output of a dynamo being as the third or fourth power of its linear dimensions in practice; so that comparing a small machine with one, say, twice its linear dimensions, the "activity" or output would be, perhaps, only $\frac{1}{12}$ of that of the larger one, and so on until after a certain point it is not even possible to get sufficient work out of a machine to excite its own magnets.

In conclusion, Professor Thompson's "Dynamo Electric Machinery" is published by Messrs. Spon, and its cost is, I believe, about 12s,—Yours, &c.,

G. C. FRICKER.

7, Charlwood-road, Putney, January 27, 1885.

[* Mr. Pardoe and "Volt-Ampere" are not one and the same. A very large number of readers are interested in this information.—ED. *E.*]

ELECTRO MAGNETS AND DYNAMO MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Two or three letters which have appeared in your columns have induced me to draw attention to the utter dearth of practical information regarding dynamo construction in any of the books which profess to deal with the subject, and the apparent ignorance on practical points of gentlemen who pass for great authorities in matters electrical. I would suggest that if your columns were opened for the discussion of the question, their value to a great many readers would be very much enhanced.

Now, sir, I am a practical mechanical engineer, and having had considerable experience in fitting up and running electric light machinery, I started a short time ago to make my own machines. I could get no assistance from the sources above referred to, and as I am a "cut above" copying, I can assure you that before I got my first *successful* machine completed the expenditure of money and time was something alarming, for every "wrinkle" obtained, or improvement effected, was the result of actual and costly experiment. Now, this is not as it should be, and I am willing to do my little best to assist in throwing more light on this important matter. As I am not an eminent electrician I cannot give much direct information, but I will undertake to be prolific in questions, the answers to which, if given *fully* and *plainly*, would be of much value. Here is a case to begin with:—

I am about to construct the armature of a dynamo, Gramme type, of which

E is the E.M.F. wanted.
D diameter of armature.
N number of turns of wire.
R resistance between brushes.
V revolutions per minute.
d distance between field magnet face and armature core.

These quantities are known, and I want to find S = cross section of soft iron armature core. Of course the more iron in armature the greater the E.M.F., provided the field magnets are sufficiently powerful to induce sufficient saturation of armature core. Now the questions I would first ask are—

1st. What is the best amount of magnetism to induce in an armature core, having due regard to heating, sparking, and other dangers, and how can that quantity be expressed in magnetic units—in fact, how is S obtained?

2nd. Having decided on this, what power must the field magnets have, and what must be the relative mass of field magnet pole, to armature core, to magnet legs, and to yoke piece? Supposing in the first case that the machine is to be

Digitized by Google

series wound, and therefore the magnets may be highly saturated, what is the best section for field magnet legs, the best relative length, and what "ampere turns" are required to give the necessary saturation?

Now, I have an experimental armature core or cylinder just making up. The diameter (D) is 8in., the length is 10½in., the thickness is 1¼in., and the cross section (S) is therefore 13·125 sq. in. The distance (*d*) between field magnet face and armature is ⅛in (⅜in. for wire, and ⅛in. clearance); *i.e.*, the field magnets will be bored 9in. Perhaps some of your readers can give me the best form and dimensions of suitable magnets —wrought iron or cast iron—and give the formulæ for obtaining the dimensions.—Yours, &c., MECHANIC.

[We have the first of a series of articles on "Dyuamo Construction" in type, and no doubt all questions by correspondents will receive the careful attention of the author.—Ed. *E.*]

HEATING BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In an article on "Railway Carriages Warmed by Electricity," published by your esteemed journal of 27th November last, you attribute all the merit of that invention to M. de Courcelle. Allow me to remark, in connection with the subject, that this is incorrect, inasmuch as some time ago I patented a similar arrangement.

In my system of heating trains by electricity, the electric current traverses the spiral metallic conductors. The foot-warmers are previously filled with a substance possessing great latent heat of fusion, such as crystallised acetate of soda or hyposulphite of soda, and are dipped in boiling water before starting.

The current has then only to maintain the initial temperature of the foot-warmers; and this task is singularly facilitated by the solidification of the acetate of soda, which, as is well known, gives out a great amount of heat. In this way the number of *calories* to be produced by the electrical machine, and consequently the mechanical energy which it absorbs, are less considerable.

In the hope that you will do me the favour to publish these few lines in *The Electrician*, accept, &c.—Yours, &c.,

D. THOMMASI.

Paris, 23rd January, 1885.

INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I don't know whether it is that my knowledge of English is deficient or that "Carbon" (in your last number) has put his query in a very involved form. If he is simply seeking information as to the comparative duration of incandescent lamps run *over* and *below* their "normal" candle-power, I beg to offer him the following average of a very extended series of tests made in the Edison Manufactory, Ivry, near Paris. The lamps were Edison's 16-candles, 100 volts:—

At 100 volts	average	life	of	lamps	was	1,000 hours.
,, 99	,,	,,	,,	,,	1,277	,,
,, 98	,,	,,	,,	,,	1,645	,,
,, 97	,,	,,	,,	,,	2,135	,,
,, 96	,,	,,	,,	,,	2,751	,,
,, 95	,,	,,	,,	,,	3,595	,,

On the other hand, running the lamps at an increased power, we obtained the following results:—

At 100 volts	average	life	of	lamps	was	1,000 hours.
,, 101	,,	,,	,,	,,	785	,,
,, 102	,,	,,	,,	,,	601	,,
,, 103	,,	,,	,,	,,	477	,,
,, 104	,,	,,	,,	,,	375	,,
,, 105	,,	,,	,,	,,	284	,,

Other than Edison's lamps, of which we tested considerable numbers, gave almost identical results.—Yours, &c.,

G. FOUSSAT.

8, Bernard-street, W.C., London, 29th January, 1885.

SMALL MOTIVE POWER FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am afraid that I am very obtuse. For the life of me I cannot master the particulars of the small installation as described by Mr. H. Davy in last week's *Electrician*. His motor house is 9 by 6; not too big I suppose, but just big enough. What is the motor—steam, hot air, gas, or what? Again, does he place the Phœnix on the coke or the hopper? If so, why so? I notice he burns a lot of coke. Why coke? Again, he has a heating coil in his house, heated, I presume, by the combination of coke, electricity, and hot water conveyed through a ¼in. lead gas tube (not too thin, but just thin enough). This last arrangement is beyond my comprehension. I always thought that lead gas pipes (compo they call them in the trade) were very thin; and what a novel idea to carry them along the cornice. Suppose they burst. I have my house heated by hot-water coils, but the pipes from my boiler are 1¼ diameter bore welded steam tube, not lead gas tube, and put in proper recesses in the walls and cased over. Now, I want to know, Mr. Editor, if my saddle boiler would drive a Phœnix machine and light up my house? If not, why not?—Yours, &c., PHŒNIX.

PROFESSOR TYNDALL ON THE SOURCES OF ELECTRICITY.

Professor Tyndall gave his second lecture on the 30th ult. Following up his previous lecture by recapitulating some of the principles which he had therein enunciated, and reminding his audience that the earlier electricians divided bodies into electrics and non-electrics, he proceeded to say that the real distinction between these bodies was not that one body was capable of being electrically excited and the other not, but that one class were insulators and the other conductors. He then gave some practical demonstrations in order to exhibit the difference between positive and negative electricity, asking his hearers to bear in mind what he had said previously, that when two electricities were mingled together in equal quantities the one neutralised the other. He showed this, first, by means of a small paper wheel, making it run after the glass rod in virtue of the attraction of the positive electricity in the latter on the negative in the former; and the converse. He afterwards repeated on his own person an experiment which he had made in the same room when he had the pleasure of lecturing on this subject some years before. Taking his stand on an insulated stool, the lecturer passed an ordinary ebonite comb through his hair ten times, discharging the comb each time by rapidly passing it through a spirit-flame, with the result that by keeping his hand at the distance of nearly a foot from a strip of lath made to revolve on a pivot, he was able to move that at pleasure round and round, just as if he had held a powerful magnet in his hand. In a like manner he exhibited the law of repulsion. He then passed on to another part of the same interesting subject, namely, to prove how electricity diffuses itself over the surface of a conductor. For this purpose he produced a metallic sphere, to which he communicated by means of the glass rod a certain amount of electricity. Taking to the electroscope, by means of a carrier, a certain amount of electricity, the same divergence of the gold leaf was observable when the sphere was touched on any side. In further proof of this principle of electric diffusion, he experimented with an electrified cone, when a remarkable change became apparent. The divergence of the leaf when he touched the extremities and sides of the cone differed very considerably; in the one case being small, and in the other large, owing, as he explained, to the tendency of the electricity to become intensified at a point which was the case at the tapering end of the cone. The next subject he drew attention to was that of hollow conductors, and for the purpose of showing that the electricity was diffused only on the outside of them, he said he wished to make use of the plainest article he could find, viz., a common teapot. Taking an electrified ball he dropped it into the teapot without letting it come into contact with the edges of the vessel, and the subsequent tests showed that the electricity was to be found only on the outer surface of the teapot, with a tendency to intensity on the spout, as shown in the previous illustration. Coming to the consideration of the influence of points, he was understood to say that Dr. Reiss, of Berlin, determined the sharpness of any given point by the density of the electricity collected on it. The lecturer then gave a very

Digitized by Google

beautiful and cleverly-executed demonstration of the use of the lightning conductor and the laws which govern it. Taking what appeared to be a brass or copper tube several feet in length, with a curvature at one end from which were suspended a number of strips of paper each about four feet in length and half an inch in breadth, he communicated the electric current to the other end of the tube by the usual process, and a remarkable effect was produced. The strips of paper, which before were in a state of quiescence, immediately seemed to take life, and spread themselves out until they resembled a cone in shape, or, perhaps, to give a more faithful description, a half-opened umbrella, exemplifying a cloud charged with diffuse electricity. Taking an ordinary sewing needle as his point, he held it under the outspread paper ribbons, which instantly began to converge with a movement similar to that which is manifested by a sensitive plant when it is touched until they were in their original position. Professor Tyndall then observed that clouds were neutralised on the same principle by the discharge of electricity from the points of conductors. At this stage of the lecture a lightning conductor of the ordinary type—that is to say, one possessing several points—was exhibited, and it is worthy of note that the learned professor said that in the case of the experiment he had just finished he had found that a single needle point was equally effective as half a dozen. At the same time, if a cloud came overhead there was no doubt that there would be an electrical discharge from all the points of a conductor, so that it might be desirable to have a cluster of them together. In this connection he said that he was reminded of a custom that prevailed all over the country which was sometimes fraught with disastrous consequences. He had been talking a few days previously to a builder, who told him of certain churches that he had protected from lightning by conductors. This builder, it appeared, was in the habit of raising the conductors above the church spires and sticking the other end of them into the ground only a few inches, in the belief that this precaution was sufficient to secure the churches against injury. Now a few years ago, when he (the speaker) had the honour of being connected with the Board of Trade, a question was referred to him regarding a lighthouse on the coast of Ireland. It was of the kind known as rock lighthouses, and a flash of lightning came down upon it, with the result that it sustained serious damage. An engineer was immediately sent to report upon the nature of the accident. It was obvious from what the engineer said that he was perfectly honest and sincere, though he did not know where to look for the cause of the disaster. But he (the lecturer) followed the description given by the engineer, and found that the lightning conductor ended in a stone, which had been pierced to the depth of six inches. It was perfectly clear that that was insufficient to carry away the lightning, and hence the damage. In such cases the conductors ought to be connected with the sea by a good conductor, ending in a plate of large surface. A model lighthouse was here exhibited, showing a process by which such a contingency might always be obviated, by having a large plate at the base, which would carry off the lightning into the water. Another experiment made in connection with the action of points, and which, he said, if it could be used, would be more useful still, was that of placing a flame under the paper strips, which caused them to converge even more quickly. Before concluding this part of his subject—namely, the action of points, the lecturer gave an illustration of electric wind issuing from the point of a needle. Having taken a small vessel of some kind, into which he poured a quantity of water, he sprinkled a little dry powder on the surface of the water, and projected powder and water upon a screen. Immediately the particles of powder were exposed to the action of the needle they were put into a state of violent commotion, being driven into streams and vortices. Before concluding his lecture, Professor Tyndall gave a few experiments illustrating the principles of the electrophorus. Throughout, it is needless to say, the experiments were watched with the closest attention, and frequently evoked great applause.

EVOLUTION OF THE ELECTRIC RAILWAY: Its Commercial and Scientific Aspect.*

BY DR. W. ADAMS, MEMBER OF THE ENGINEERS' CLUB OF ST. LOUIS.

(CONCLUDED FROM PAGE 228.)

We come now to a practical application of these data.

Suppose we wish to determine whether it will pay to operate a street railway by electricity: Knowing the horse-power which the motor must develop in order to move each car or train over the given maximum grades at a given speed, and knowing the greatest current the conductor we provide can carry without losing more than the prescribed amount, it remains to calculate the electromotive force which the motor must develop.

Supposing the electrical efficiency of the motor to be eighty-five per cent., then $H = \frac{Ie}{746} \times \frac{85}{100}$, because the counter E.M.F. (e) generated by the motor multiplied by the current traversing it measures the *electrical* work it performs. Then $e = \frac{H \times 746}{I} \times \frac{100}{85}$.

In order to find the E.M.F. of the generator (E):

$$\frac{E}{e} = \frac{W}{w} = \frac{I\,e + I^2\,R}{I\,e} = 1 + \frac{IR}{e}\,;\quad E = e + I\,R.$$

Upon these and the preceding expressions are based the following estimates as to the comparative cost of operating a street railway by horse-power, electricity and cable:

COST OF OPERATING ELECTRIC SYSTEM.

44 Cars. *Speed*, 6 *Miles.* *Length*, 5 68-100in.

22 cars acting as locomotives, each one having an additional car attached, and being provided with 8 horse-power.

22 cars, 8 horse-power, multiplied by 2, on the supposition that we get but 50 per cent. return instead of 70, as is possible, = 352 = total horse-power consumed when all the cars are running and consuming full 8 horse-power, a condition which never exhibits—even at such times when the road is working at maximum capacity.

Average power consumed during the running hours ...	200 h.-p.
Pounds of coal consumed, five horse-power per hour...	2½
Total amount of coal consumed per hour.....	500lb.
Working hours per day	20 hours.
Pounds of coal consumed per day	10,000lb.
Cost of coal per 1,000lb., $1.00.	

	Dollars.
First Item.	
10,000lb. of coal at $1.00, $10.00 = cost of coal per day.	
Cost of coal per year	3,650
One engineer at.....per day	5.00
One assistant engineer at .....per day	2.50
One electrical engineer at.....per day	5.00
One assistant electrical engineer at .....per day	2.50
Two stokers at $2.50.....per day	5.00
Second Item—	
Total cost of labour at station per day	20.00
Yearly cost of labour at station	7,300
Third Item—	
Yearly oil and "waste"	500.00
Fourth Item—	
One conductor to every two cars at	2.00
One driver ,, ,, ,, ...	2.00
Cost of labour on each train.....	4.00
No. of trains	22
Total cost of labour on cars per day	88.00
Total yearly cost of labour upon cars.....	32,120.00
Three steam engines of 208 horse-power each	7,500.00
Fittings for same	1,500.00
Two Babcock and Wilcox boilers of 460 horse-power	8,500.00
One Babcock and Wilcox boiler of 146 horse-power capacity	4,070.00
Fittings for boilers.....	1,000.00
Extras	1,000.00
Total net	23,570.00

Four electric circuits of 2¾ miles each, having conductors with electrical capacity of 500 amperes and having a resistance of but one-fifth of the entire line, where each generator and each motor has a resistance of 10 ohms, and of which there are 11, arranged in multiple circuit, equal a copper bar of half an inch in area, costing, at 30 cents per pound:

Cost of copper conductor per mile.....	2,890.60
No. of miles	11
	31,790.00
Cost of conduit and tramway per mile of double track	40,000.00
	2¾
	110,000.00
Electro-motor fittings to 22 cars at $1,000 each	22,000.00
22 electric generator motors at $2,000	44,000.00
4 surplus generators.....	8,000.00
Total cost of generators	52,000.00
Wear and tear on item of motors at 8 per cent.	1,320·00
Wear and tear on generators at 4 per cent.....	2,000.00
Wear and tear on engines and boilers	3,000.00
Wear and tear on cars, conduit and tramway	11,000,00
	17,320.00

* Paper read before the Society of Civil Engineers, America.

Digitized by Google

Total Yearly Wear and Tear.

Wear and tear of conductor	Nothing.
44 cars	50,000.00

Yearly Running Expenses.

Fuel	3,650.00
Station labour	7,300,00
Waste and oil	500.00
Labour on cars	32,120.00
Wear and tear as itemised	17,320.00
Total	60,890.00
Yearly interest on capital invested	17,361.60
Yearly expenses, including interest	78,251.60

Capital Invested.

Motors	22,000.00	
Generators	52,000.00	
Engines and boilers	23,570.00	
Electric conductors (copper)	31,790.00	
Conduit and tramway	110,000.00	
Forty-four cars	50,000.00	
Total	289,360.00	
Interest at 6 per cent.	17,361.60	
Present yearly earnings of road upon which this estimate is based		177,000.00
Above estimates suppose the work done to be doubled, and, consequently, the income doubled, making		354,000.00

Estimated from data furnished by a railway company—Present cost of operation with horses—Details of estimate.

	Dollars.
22 cars, earning capacity	177,000.00
Capital invested	225,000.00
Interest at 6 per cent.	13,500.00
Wear and tear at 10 per cent. on invested capital, less cost of horses, the wear and tear of which is included in item of $11,710.20; allowing $25,000 to be deducted from the $225,000 as the cost of horses, leaves as invested capital to reckon 10 per cent. wear and tear upon	200,000.00
Interest at 10 per cent.	20,000.00
Feed	31,689.60
Running expenses of stables and contents	11,710.20
Stable expenses	2,185.00
Blacksmithing	2,356.20
Total	47,941.00
One conductor on each car at $2.00, and one driver at $1.50 22 cars, cost of labour on cars per day	77.00
Yearly cost of labour on cars	27,874.00
Result:	
Interest at 6 per cent.	13,500.00
Wear and tear on $200,000 at 10 per cent.	20,000.00
Total cost of propelling power	47,941.20
Yearly cost of labour on cars	27,874.00
Total yearly running expenses	109,315.20
Will average about	115,000.00

COST OF OPERATING CABLE SYSTEM.

The amount of coal consumed on the Clay-street Railroad is 3,600lb. per day of 17 hours, costing $8 per ton.

Cost of Cable Road Construction.	Dollars.
Will average per mile of double track	200,000
3 miles	600,000
2 horizontal engines, 14in. by 30in., set up	5,800
2 boilers, 52in. by 16ft., set up	4,500
Tank, pump, and heater	1,500
Compensating arrangement at end of line	1,800
Driving machinery, pulley, &c.	6,500
22 cars at $1,000	22,000
22 dummies fitted with grips at $900	19,800
Engineering sundries, at 10 per cent., in round numbers	25,000
Total cost of three miles complete	686,900
Interest at 6 per cent.	41,214

Cost of Operation.

Maintaining cable per year		15,000
Oil and waste		500
Maintaining conduit, tramway and cable bearing sheaves, 10 per cent. on $600,000		60,000
Interest on capital invested, at 6 per cent.		41,214
In round numbers, 600 tons of coal, at $8		4,800
One engineer at $5.00 per day; one assistant engineer at $3.00 per day; two stokers at $2.50 per day—labour of station per day	13.00	
Yearly cost of labour at station		4,745
Cost of labour per day, 22 trains	88	
Yearly cost of labour upon cars		32,120
Total yearly cost of operation		158,379

COMPARISON OF RESULTS.

By Horses.		*By Electricity.*	
Capital invested	$225,000.00	Capital invested	$289,360.00
Earning capacity	177,000.00	Earning capacity	354,000.00
Running expenses, including interest—best year out of ten	109,315.20	Running expenses, including interest	78,351.00

Power consumed, and, consequently, the cost of operation the same whether you carry 3,000,000 passengers or 2,000,000.

Want of flexibility as regards ability to regulate the capacity of the road in accordance with the varying demands at different periods throughout the day.

More details to attend to. Such as buying and disposing of horses. All of which makes more clerical work and largely occupies your own personal attention.

More at the mercy of unscrupulous *employés*, as regards the attention they give your horses.

Want of flexibility of the system renders it necessary to at times overcrowd the car, and thus is the road made unpopular.

Capital confined to street railroading.

Power consumed, and, consequently, cost of operation, more nearly proportionate to the work done, or the *earnings*.

Great flexibility—rendering it possible to exactly adapt the capacity of the road to the varying demands.

After plant is once established but little attention is required outside of keeping same in repair.

Amount of attention and care given to machinery manifest on the surface.

Great flexibility (that is ability to change the capacity of the road to suit varying traffic) renders overcrowding unnecessary, and have the road become more *popular* and more generally patronised.

Power may be distributed throughout the district amounting to 2,000 horse-power with same street plant and but little additional yearly expense, and bring in an income of over $300,000 a year.

LEGAL.

The Liquidators and a Contributory.

IN RE THE UNION ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

This case was heard before Lords Justices Baggallay and Fry in the Court of Appeal on Monday, 26th January.

This was an appeal by a contributory (Mr. Andrew Hutton) from an order of Mr. Justice Pearson on the 6th of December last, refusing to remove the liquidators, Mr. Wilwyn Parish, Mr. Alfred Parish, Mr. John Goddard, jun., and Mr. James Fyfe, former director, in a voluntary winding-up.

Lord Justice BAGGALLAY in giving judgment, said this was an appeal against an order of Mr. Justice Pearson, on the 6th of December last, dismissing an application to have removed the four gentlemen who had been appointed liquidators of the Union Electric Light Company (Limited). Mr. Justice Pearson had thought that it was not a case to move some of the liquidators, but a case for removing all or none, so he simply dismissed the application. Now, this company's history was not an inapt illustration of the way in which many companies were born, lived, and died. The Company was registered with a capital of 300 shares, £100 each; its object was to buy certain electric light patents. They were told that the history of the Company was this—that a syndicate had been formed for the purchasing of those patents, and to sell them again at a profit, and they thought it would be more convenient to form themselves into a company, not for trading, but for speculation. Well, that was not the purpose for which a company ought to be formed at all; however, it was formed on the 3rd April, 1882, and an agreement was entered into with a Mr. Fyfe (who was subsequently appointed one of the liquidators), the vendor, who was to sell certain specified Letters Patent for £10,000 in cash, £5,000 of which was to be paid on the signing of the agreement, and £5,000 more on the company being formed, and two-fifths of the nominal capital in fully paid-up shares—that was to say, out of the company formed with £250,000 capital he was to have £100,000 in fully paid-up shares, and if he procured certain foreign patents for the company he was to have a further sum of £5,000. Whether it was a high price or a low price he (Lord Justice Baggallay) was not prepared to say, but the gentleman who was appealing was perfectly well aware of the facts, as he was originally one of the syndicate. This showed the very large interest Mr. Fyfe had in the company. Well, the company carried out its object by selling to another company, the Pilsen-Joel and General Light Company, the English patents for £15,000 in cash and 12,000 £5 shares, probably intended for distribution amongst the shareholders in the Union Company. These Pilsen shares at one time rose to £4 10s. premium, but eventually, when realised, fetched £1 3s. each, which was a very considerable discount. There were substantially the same Directors of the Pilsen Company as of the Union Company, with which the Court was now dealing, and the suggestion had been made that these shares, which at one time might have been realised at a premium, were kept back in the interests of those Directors of the Union Company who were also Directors of the Pilsen Company. Now, amongst the voluntary liquidators who were sought to be removed were the four directors of the Company. He (the Lord Justice) did not for one moment say that the Directors of a company in a voluntary liquidation were not proper persons to be appointed. Hence the suggestion was that the four voluntary liquidators of the Company—one being Mr. Fyfe, the vendor—were not the right persons to investigate the affairs of the Company. With regard to the first point, namely, that there was a large loss in respect of those shares which might be deemed a subject of inquiry, though it certainly was a very singular transaction, he did not say that necessarily it was a charge that would be established. He presumed that the shares had arrived at a considerable discount when it was set forth in the report to the shareholders that if there should be

Digitized by Google

some improvement in electric lighting prospects it was possible the shares in question might fetch their full value. At those meetings the matter seemed to have been fully discussed, and the majority of the shareholders appeared to have been favourable to the course that had been taken, and on that ground it did not appear to him to be a reason for changing the liquidators. Another point was that the company having sold all its English patents, and having no power to grant any licenses for the use of those patents in England, the directors went to considerable expense (£2,000) to obtain provisional orders. It certainly seemed a large expenditure to have made at a time when the company had no patents whatever in England. He should have thought that this was almost a *primâ facie* ground that there was an error in what they had done, and that it was better that some independent liquidator should be appointed. The report for the general meeting in 1883, giving all the accounts down to that time, including this item, was passed and approved at the formal meeting, and he was disposed to think that the gentleman now appealing must be presumed to have been aware of these matters, and if he chose to stay away from the meeting he must take the consequences. Therefore, upon that ground he thought this gentleman was precluded from raising the point afterwards. Another point was that £1,600 had been paid to the Directors ; but that sum did not appear to him to have been a large amount in excess of what the articles provided, and no doubt that was a matter entirely within the scope of the company ; and the chief ground of complaint was that one or other of these gentlemen were not duly qualified. But at the time one had gone to America for a purpose which seemed satisfactory to the other Directors. Therefore, that was not a point to attach much importance to in itself. He came now to a circumstance which appeared to him of a very much graver character. On the 19th March, 1884, when the company was approaching its death, an agreement was entered into between Mr. Fyfe, the vendor, and the company, itself represented by himself and the three other Directors at the time, and it would seem by it that Mr. Fyfe was to some extent indebted to the company. The agreement stated, "And whereas there have been divers further transactions with reference and the rendering by James Fyfe of certain services and providing by him of offices, materials, &c., and the said James Fyfe claims a considerable balance is due to him, which the company does not admit." Then an agreement was come to by the company to pay him £100. Well, there again, if this had been brought before the shareholders at their general meeting, he should have thought, if they had chosen to adopt the terms, that would have been sufficient to bind them ; but he could not find that any such communication had been made to them. They were invited to meet and resolve on liquidation, but were not informed of this, and they confirmed the resolution of the voluntary liquidation passed on the 26th August ; and before the month of August a certain document was sent round and signed by a number of the shareholders, including Mr. Hutton. The document was in these terms:—"We, the undersigned shareholders, hereby approve the proposed reconstruction of the company, and agree to vote for the resolutions." Substantially it had reference to a certain agreement with reference to the reconstruction. The meeting was held on the 22nd, and Mr. Hutton was present, and the minutes say the resolution was passed "nemine contradicente." Mr. Hutton says he did not vote for it, but it does not seem that any one earnestly opposed it. Subsequently, on the 29th September, when the formalities of the reconstruction were apparently over, and on the footing of a deed produced, dated the 29th December, an agreement was expressly entered into by the four liquidators of the company and Mr. Funnell, the secretary of the newly-formed company, and it referred to all the resolutions passed at the general meeting held on the 22nd August, 1884. This document was presented at the meeting on the 22nd August, at which Mr. Hutton was present, and it contained no less than four clauses, all introduced for the purpose of giving effect to the provisions. It was, he thought, preposterous for this gentleman now to come forward and say he was kept in ignorance of it, as he had an opportunity of considering it, and for him afterwards to turn round and say, though it was true he signed the memorandum and was afterwards present at the meeting and had not opposed it, that it was a document which was concealed from him. There was one other matter which he (the Lord Justice) must refer to, because he was bound to say he did not like these things, and did not think them nice in the history of the company ; but, at the same time, if they had been adopted by the shareholders, the Court could not afterwards interfere with them. There was no intimation whatever given as to the purposes of the general meeting after the liquidation. Mr. Hutton endeavoured to obtain information, and they refused to give him any. He thought that was a very serious breach of duty. This person had let them know that he had not taken the same view as the other shareholders did, and wanted to know what was going to be done at the meeting irregularly called. He had come to the conclusion, having regard to all the facts of the case, that the Court ought not to interfere with the decision of the learned Justice below refusing to remove the liquidators, but that no costs should be allowed, and by that he did not mean to say that the parties were to get their costs out of the estate.

Lord Justice FRY concurred, and added that he had no doubt of the jurisdiction of the Court to remove liquidators, but at the same time the exercise of the discretion of the learned Judge below would always have great weight with that Court. That the liquidators in this case had been guilty of impropriety of conduct he had not the slightest doubt. With regard to the meeting of October, 1884, that meeting they summoned for the purpose of considering their acts as liquidators, and they appeared to him to have had in their minds the intention of closing the mouth of Mr. Hutton in case he should raise any objection to their proceedings, when it was their bounden duty to give due notice to the shareholders of the character of the meeting ; and having regard to the great impropriety of the liquidators, they would have to pay the costs of this appeal personally.

COMPANIES' MEETINGS & REPORTS.

Eastern Telegraph Company (Limited).

The half-yearly general meeting of the shareholders in this Company was held on the 29th inst. at the Cannon-street Hotel, under the presidency of John Pender, Esq., M.P.

The SECRETARY (Mr. George Draper) read the notice convening the meeting and the report of the Directors, which has appeared in *The Electrician*, was taken as read.

The CHAIRMAN stated that the gross receipts for the half year ended September 30 last had been £309,569, being an increase of £26,499 over those of the corresponding period of 1883. About £19,000 of that increase had been derived from long Government and Press messages, which had compensated the Company for the falling off in the number of commercial telegrams. The Black Sea Company's traffic showed the sum of £2,023 against £623 in the corresponding period of the previous year, which had to bear the cost of two repairing expeditions. During the six months under review they had had no interruption of the Black Sea line. Their receipts for traffic with India had been £4,000 less. The balance sheet showed that they had £3,498 in shares of the Mediterranean Extension Company, which was now in liquidation. They anticipated that this amount would be realised at a profit before the next accounts were published. Their working expenses had been £84,907, or £4,058 more than in the corresponding half of 1883. This increase had arisen for the most part from exceptional charges, which he alluded to. The salaries and wages at stations had been £2,045 more, but they had opened four new stations—Suakim, Pireaus, Patras, and Katacolo. There were also six months' working expenses of their new station at Glasgow against two months of the corresponding period. The cost of the Lipari and Messina cables had in the past half year been £884, against £1,000 for the last five half years, and the capital cost of these cables—£5,884—had now all been charged to revenue. The expenses attending repairs and renewals of cables had been £31,189, or £1,669 more than in the corresponding period of the previous year. After charging all expenses, including income tax on the net revenue, providing for interest on debentures, debenture stock, and preference shares, they were enabled to pay a dividend with bonus at the rate of 6 per cent. per annum, and to carry forward £30,364, against £13,679 in 1883. With regard to the traffic with India, they knew very well now, from long experience, that the success of the telegraph system—or an increase or decrease in the number of messages—depended more or less upon the state of trade ; and there had been a very marked depression of trade both in India and England. They nevertheless presented a good account, a circumstance which was owing to the state of things in China. He would, however, rather trust to buoyant and active trade than to war operations for a successful return on their enterprise. The next matter he had to refer to was one of considerable importance. When the report was printed it was stated that all their cables were in perfect working order. That was fourteen days ago. That day, however, they had several cables interrupted, but, thanks to their arrangements and to having their ships placed at a proper point to meet immediate repairs and requirements, he trusted that within a very short time indeed they would have their cables at work again. He wished particularly to impress this point on them—that while they had breaks they knew where the breaks were, and had perfect confidence in being able to repair them. This, however, necessitated their having ships at different points, and they were more or less expensive. Still, they could not do without them. They now had their system so arranged in the Mediterranean that if they had one, two, or three—or even four—cables interrupted they would still be able to conduct their important traffic with the Continent and their large traffic with India, China, and Australia. They had—possibly what the shareholders were not aware of—many alternative routes. During the present pressure of war intelligence and urgent messages on military affairs they had been enabled to utilise their two cables from Alexandria to Malta and Marseilles, secondly those from Alexandria to Zante and Otranto, and thirdly from Zante to Trieste, and from Alexandria to Constantinople and Odessa. They had these four important alternative routes to the Continent and Egypt, besides the line *viâ* Gibraltar and Lisbon, which had been totally interrupted for the last five days. They were therefore now, with many interruptions, still doing their work in a way which the public could have no cause to complain of. He was sure they would all join with him in expressing deep regret at the loss which the nation had sustained by the death, at the seat of war, of Mr. Cameron, the special correspondent of the *Standard*, and of Mr. Herbert, the special correspondent of the *Morning Post*. He did not consider it at all out of place at that meeting for him to refer to the splendid services which the correspondents of the daily newspapers rendered to their employers and the public ; and he might mention, incidentally, that on more occasions than one they had received telegrams from these gentlemen which had cost the papers they represented from £300 to £500. The last time he addressed them he stated that they had connected Suakim with their system, and that Suakim was likely to be the opening to the Soudan. It was at that time generally supposed that any expedition sent from this country would go by Suakim to the Soudan. When he looked at the hundreds of thousands of pounds spent in going in that direction compared with the millions spent in going in other directions, and when his opinion was more the opinion of men of great experience, he regretted on many accounts that Suakim was not the road by which the Soudan had been approached. If the railway had been made it would have developed a new trade in that country, have prevented the slave trade which England had done so much to keep down, and in every respect he believed the result would have been more satisfactory had we gone to the Soudan by Suakim. He sincerely trusted, however, as it was, that the outcome of the course which had been taken would be

Digitized by Google

beneficial to the nation. They had now obtained possession at a moderate price of the undertaking of the Mediterranean Extension Telegraph Company; and they had also acquired a controlling interest in the Direct Spanish Telegraph Company. These were now links—and they might ultimately become important links—in the Company's system of cables. The arrangement made with the Greek Government—to which he had alluded at their last meeting—was regarded as so satisfactory by that Government that they afterwards offered the Company an extension of the subsidy of £6,500 a year for ten years, making thirty-three years, if they would connect some of the outlying islands of Greece. The fresh connections would cost the Company about £6,000, so that, on the whole, this was not an unsatisfactory arrangement. They had also opened a station at Perim, in the Red Sea. They had done this under a guarantee from an enterprising company established there—the Perim Coal Company—that their expenses should be paid, and they expected that the traffic from that place would be something considerable eventually. The whole of our mercantile fleet was composed of steamships which must coal somewhere; and what was the value of our great ironclads if we had not good coaling stations? He believed this was going to be a great question of the day, and it was the interest of this Company "to follow the flag" as far as they could. He concluded by moving the adoption of the report and accounts.

The VICE-CHAIRMAN (the Marquis of Tweeddale) seconded the report.

The CHAIRMAN, in reply to questions by Messrs. E. P. Evans, Watkins, John Newton, and Sherwin, stated that the reserve fund was the backbone of a cable company. As to placing the interest of the reserve fund to the general revenue account, instead of adding it to the reserve fund, if the accountants could be induced to sanction it, he did not think the Directors would be found difficult to deal with in the matter. They received no dividend on the shares of the Direct Spanish Company, but they had 6 per cent. on the debentures.

The resolution was then unanimously adopted.

The retiring Directors—Mr. Pender and the Marquis of Tweeddale; and the auditors—Messrs. Henry Dever, and Messrs. Quilter, Ball, and Co. were afterwards reappointed; and a cordial vote of thanks to the Chairman, Directors, and staff brought the proceedings to a close.

[We shall publish a full report of this meeting in our next issue].

Cuba Submarine Telegraph Company.

The twenty-seventh ordinary general meeting of this Company was held on Wednesday, at the offices, No. 61, Old Broad-street, Mr. Joaquin de Mancha presiding.

The SECRETARY (Mr. James Scott) read the notice convening the meeting, and the report was taken as read.

The CHAIRMAN: Well, gentlemen, the report and accounts having been taken as read, I must offer a very few observations, for I consider that they so clearly and substantially convey the whole of the proceedings of the last six months that it requires but very few observations on my part. I think we must congratulate ourselves that the report is so very favourable, taking into account the great difficulties that all sugar-growing countries have experienced during the last few months. We find, notwithstanding, that Cuba has produced for us 981 messages more than at the same period last year, which I think is very satisfactory for our interest. I am only sorry to say that the receipts have not kept up in the same proportion, for although we have carried more messages our income has been about £400 less than it was in December of the previous year. That, as I have before explained arises from the great knowledge that gentlemen who use the telegraph now possess; they are more versed in conveying messages, and one word very often includes a whole sentence. I know for myself that we have one word which signifies "We have paid into your account," or "We cable £5,000 to the credit of Mr. So and So, Barcelona." Therefore one word conveys the whole gist of all the telegram which, in former times, used to be more explicit than it is now. You see, gentlemen, that besides having added to the reserve fund, its own interest—which amounts to £1,400—we have been able to add out of the profits of the half year £550 more, bringing up the reserve fund now to £60,000, which, I think, you will consider a very favourable amount to have at our disposal [applause]. This sum we of course hope to continue adding to, for telegraph and cable property is rather dangerous, and very often breaks down, and it might be unacceptable to find an expenditure of £4,000 or £5,000, or it might be, as at one time, nearly £20,000. Therefore my colleagues and myself consider that it would be advisable to allow that fund still to accumulate [applause]. The money we have in hand, you will see, will enable us to pay the £3,000 on the preference shares, and we recommend to you that a dividend, free of income tax, be paid at the rate of 7 per cent. for the half year, which will absorb the whole of the amount except £400, which we will carry forward to the next account. In paragraph 5 it is very satisfactory to find that the cables are all in excellent repair. We have had letters lately from Mr. Keith, our engineer, who says they are all working in perfect order, and we hope they will continue to do so. It has been necessary for us to buy a small piece of land for the putting up of tanks for some cable we have there in case of necessity. This has entailed the expenditure of a trifling sum, which rather increases the expenses as you will find, but it is not very large. It amounts to about £177, but it is an expenditure which we consider is well laid out, and it has enabled us to have our spare cable re-coiled, so that in case of necessity it will be available for our purposes [applause]. As to the old question of the tax to be returned by the Spanish Government, when this report was written it had not yet been received, but since then we have had a letter from Mr. Keith, and also a telegram, by which it seems that the Government have not funds at present to pay us, but they promise to do so. The telegram was received yesterday, and the Secretary will read it.

The SECRETARY, reading: "On Monday Crow says our claim will be paid out of first cash remittance received from Spain. Expected about 5th prox." That is the 5th of February.

The CHAIRMAN: So that we hope that paragraph will be expunged from our next report, and that we shall be able to tell you that the sum of about £1,100 has been received and carried to profit and loss. I think, gentlemen, these are the few words I have to call your attention to, and therefore I will now ask you to pass the resolution—"That the report and accounts now submitted be received and adopted" [applause].

Mr. ALEXANDER F. LOW seconded the resolution.

Mr. WOODWARD asked for some information as to the item of loan on securities, £4,000; also as to the amount of sundry creditors. He also considered that the sum of £10,000 lodged with the banks on deposit was too large. It was not wise to put so many eggs in one basket, and he would therefore be prepared to move as an amendment "That no larger sum than £5,000 of this Company's money be lent to any one bank, or for a longer period than six months."

Mr. PREST, while congratulating the Board on the excellent way in which the Company's affairs had been administered, would be ready to second this amendment as a matter of precaution.

Mr. GRIFFITHS thought it would be wise to accept the report, and bring forward this proposal as a separate resolution. He complimented the Board on the manner in which they had managed the Company's affairs, and asked the time for which the concession would still run.

The CHAIRMAN said he would answer the questions they had placed before him. First of all, Mr. Woodward had inquired what security they had for the loan of £4,000. That was the spare money they had in hand for the dividend, and as they could not employ it in anything more profitable than lending it on the Stock Exchange, they lent it to a very respectable broker on securities that were worth £6,000 [applause]. By that means they were able to get 4½ per cent. They had called up the money that day so as to be ready to meet the dividend. He thought it quite right that gentlemen should ask questions, and they would answer them all, he hoped, to their satisfaction. The next question was about the sundry creditors. He had them all there. First of all there was an amount which they had to pay to Mr. Hooper for the cable that they were then using. He did not know whether that gentleman had been here before.

Mr. WOODWARD: No.

The CHAIRMAN thought he had explained before that they had to pay so much a year—£4,000 a year. They had paid £2,000 out of the profits this year, and that was the amount they had to pay Mr. Hooper as the proportion of the cable up to the present time. That amounted to £2,962. They got that back in case of any fault being found. Mr. Hooper was bound to repair it at his own cost, therefore they had retained a certain sum which went on accumulating until it gets to £5,000, when he got his full allowance. Until then they retained a certain portion, so that in case of an accident they had a guarantee that the cable would be repaired.

Mr. GREENWOOD (the auditor) said he did not think it was wise that those matters of detail should go out to the general public.

The CHAIRMAN believed they had nothing to hide. As to the other sums, there was a reserve for the income tax and an amount they owed to Mr. Ramsden, one of the managers. They had plenty of money to pay for them. The next thing was the deposits with the banks. Most of the gentlemen present knew about banking, and that it was a very difficult thing at the present time to employ money at 5 per cent [applause]. A gentleman said that there were plenty of things knocking about to pay 4½ per cent. He wished he would only send a list of them, and he would be glad to invest in them. He knew there there was the greatest difficulty in getting 3½ interest on railway debentures. He hardly thought there was a railway in England which would pay more than 3½ per cent. [applause]. He thought the question was for them to say what they wished done, but he should not like to have Mr. Woodward's proposal put as an amendment [applause]. They would express their ideas that they thought it would be more prudent not to have more than £5,000, and if they left it for the Board to deal with they would endeavour to bring it down to that figure. There was the Chartered Bank of India. They had £10,000 in that bank, which he knew was refusing money. In that bank they had not only the security of the paid-up capital of the bank, but more than that; and even in the case of the Oriental Bank, the whole of the depositors he believed would get every shilling which was owing to them. This was not like a private bank in England in which there were no shareholders. In most of those banks there were perhaps 1,000 or more shareholders, and if the bank went wrong they were liable for double the amount which they had subscribed. Therefore, though it might seem a large sum deposited with these banks, he must say that any gentleman who knew anything about the business would feel perfectly satisfied, even if they had ten times that amount with them.

Mr. WOODWARD objected to the sum of £10,000 in any bank.

The CHAIRMAN said that was a matter they would bear in mind, and he would be sorry if that question were put as an amendment. He did not think, indeed, they could put it as an amendment. None of those banks would receive money for less than a year, and some for sixteen months. They required three months extra, so as to get the money from the Colonies if they called it in.

Mr. WOODWARD contended that that made his argument stronger.

The CHAIRMAN, in reply to Mr. Griffiths, said that the concessions had still about thirty years to run.

Mr. WOODWARD here intimated that he would be happy to withdraw his amendment, and the report and accounts were unanimously adopted.

The CHAIRMAN next proposed "That the following dividends for the half year be now declared upon the shares of the Company, viz., at the rate of 10 per cent., subject to income tax, on the preference shares; and at the rate of 7 per cent., free of income tax, on the ordinary shares, payable on and after to-morrow."

Mr. LOW seconded the resolution, which was agreed to.

Digitized by Google

Mr. WOODWARD then proposed "That it be a recommendation to the Board to distribute their investments, so as not to have more than £5,000 in any one security."

Mr. PREST seconded the resolution, which was carried.

On the motion of Mr. GRIFFITHS, seconded by Mr. WOODWARD, a cordial vote of thanks was passed to the Chairman and Directors, and the proceedings terminated.

The Direct United States Cable Company (Limited).

Report of the Directors for the six months ended 31st December, 1884, to be presented at the fifteenth ordinary general meeting of the Company to be held at the Cannon-street Hotel, on Thursday, February 5th, at 2 p.m.:—

For the half year the revenue, after deducting out-payments, amounted to £68,824 5s. 2d., against £73,472 12s. 7d. (after similar deductions) for the corresponding half year of 1883, being a difference of £4,648 7s. 5d. against the half year under review. The working and other expenses, including interest on debentures and income tax, &c., amounted to £18,607 15s., leaving a balance of £50,216 10s. 2d. as the net profit of the half year, making, with £2,786 8s. 7d. brought forward from the previous half year, a total balance of £53,002 18s. 9d. For the corresponding half year of 1883 the working expenses and other payments amounted to £21,824 4s. 5d. Interim dividends of 1¼ per cent., each for the quarter ending 30th September, 1884, paid 15th November, 1884, and for the quarter ending 31st December, 1884, payable 16th February, 1885, together amounting to £30,355, have been declared. The sum of £5,396 15s. 10d. has been set aside to the reserve fund, which after being charged with £73,367 14s. 7d. on repayment of the debenture loan now amounts to £300,000. A balance on the revenue account of £17,251 2s. 11d. has been carried forward. The debenture loan of £100,000 was paid off on the date due, viz., 15th October last. On the 24th December last, the Mackay-Bennett cables opened for business at a tariff to New York of 1s. 8d. per word. The tariff of this Company was on that date reduced to the same rate.

Anglo-American Telegraph Company (Limited).

Report of the Directors to the ordinary general half-yearly meeting of the proprietors to be held at the City Terminus Hotel, Cannon-street, on Friday, February 6th, at 2 p.m.:—

The total receipts from the 1st July to the 31st December, 1884, including a balance of £2,503 11s. 5d. brought forward from the last account, amount to £243,066 12s. The traffic receipts show a decrease of £12,136, as compared with the corresponding period of last year. The total expenses of the half year, including repair of cables, &c., as shown by the revenue account, amount to £52,639 17s. 4d. The Directors, under the powers conferred upon them by the Articles of Association, have, before declaring the net profits, set apart the sum of £75,000 to the renewal fund, leaving a balance of £115,426 14s. 8d. Interim dividends of 15s. per cent. on the ordinary stock, and 30s. per cent. on the preferred stock were paid on the 1st November last, absorbing £52,500, leaving a balance of £62,926 14s. 8d., out of which the Directors recommend the proprietors to declare final dividends, less income tax, of 17s. 6d. per cent. on the ordinary stock, £1 10s. per cent. on the preferred stock, and 5s. per cent. on the deferred stock, amounting to £61,250, making a total distribution for the year ended the 31st December, 1884, of £3 2s. 6d. per cent. on the ordinary stock, £6 per cent. on the preferred stock, and 5s. per cent. on the deferred stock, leaving a balance of £1,676 14s. 8d. to be carried forward to the next account. The Company's repairing ss. "Minia" has been engaged during a portion of the past half year in the repair of the Rantem and Island Cove cables. She has also been engaged in the repair of the Western Union Telegraph Company's cables off the Great Bank of Newfoundland, having been chartered by that company for the purpose. The Company's system of cables and land wires is in good working order. The Commercial Cable Company (Mackay-Bennett) opened their cables to the public on the 24th December, 1884, at a tariff of 1s. 8d. per word from the United Kingdom, and 2 francs per word from France to New York and Canada, and at 40 cents per word from New York and some of the principal cities in the United States to the United Kingdom and France, being an average reduction of about 20 per cent. The Atlantic cable companies parties to the joint purse agreement adopted the above rates from the same date. In consequence of this reduction, a loss estimated at about £170,000 a year will be incurred by the companies engaged in carrying the traffic, there being no reasonable expectation that this decrease of revenue will be recouped to the companies by an equivalent or even appreciable augmentation in the number of messages. In accordance with the Articles of Association, two Directors of the Company, Sir James Anderson and William S. Cunard, Esq., retire at this meeting, and, being eligible, offer themselves for re-election. Mr. Joshua Dean and Mr. Francis Glass, the auditors, also retire and offer themselves for re-election.

Dundee and District Telephonic Company (Limited).

Report by the Directors to the annual general meeting of the shareholders to be held on Wednesday, February 4, 1885, at 12 noon:—The Directors have pleasure in submitting to the shareholders the accounts and balance sheet of the Company for the year ending 31st December, 1884. In terms of a resolution come to at a meeting of the Company held on 6th February last, and duly confirmed by a meeting held on 21st February last, the capital of the Company has been increased from £5,000 to £10,000. Of the new shares authorised to be issued 372 shares of £5 each have been subscribed for, and on these the sum of £2 5s. has been called up and duly paid. The number of wires rented at the close of the year was 340, being an increase of 20 on the previous year, which, considering the opposition with which the Company has to contend, the Directors regard as gratifying. The net balance of revenue amounts to £633 13s. 7d., which the Directors recommend should be applied as follows:—To reserve fund (which will then amount to £800), £200; to payment of a dividend at the rate of 5 per cent. per annum, free of income tax, £252 17s. 3d., leaving a balance of £180 16s. 4d. to be carried forward to next account, subject to such remuneration as may be voted to the Directors.

Anglo-American Brush Electric Light Corporation.

Report of the Directors for the year ended 31st Dec., 1884:—

The need for a lengthy report upon the proceedings of the Corporation during the past year is lessened by the publication in July last of an *ad interim* report, which informed the shareholders of the business and progress effected during the first half of the year, and by the issue of the circular in view of the extraordinary general meeting, on 22nd December, at which the provisional agreements for the absorption of the Great Western Electric Light and Power Company, and the Brush Midland Electric Light and Power Company were adopted. The shareholders will have concluded from the half-yearly report already referred to, as well as from the universal depression of trade throughout the country, that the expectations of a revival of business entertained a year ago have not been realised to the full extent. Nevertheless, the Board have the satisfaction of being able to congratulate the shareholders upon the great advance made by the Corporation, and upon the decidedly improved position which electric lighting occupies among the industries of the world. The progress made by the Corporation in perfecting its apparatus and in extending its business has been very considerable, and, consequently, good progress has been made, as will be seen from the accounts, towards attaining a dividend-paying position. This advance is in a large measure attributable to the fact that the Corporation have extended the scope of their operations by undertaking the work of contractors, and to their having secured important and remunerative contracts from the Government, and other sources for the installation of the electric light; and the Directors are glad to recognise in the cordial manner in which the proposal to amalgamate with two of the subsidiary Brush Companies was agreed to, that the shareholders appreciate and support the policy of the Board, which renders possible this extension of the sphere of operations. The concentration of the manufacturing works, begun in 1883 by the removal of the incandescence department from Portpool-lane to Victoria Works, proved so marked a success, both directly and indirectly, in the reduction of expenditure, and in the increase of general efficiency which resulted therefrom, that the Board determined, after careful consideration, to continue this concentration by arranging that the operations hitherto conducted at the Borough-road premises should be carried on as far as practicable at the Victoria Works. The economical advantages resulting from this concentration of work are not fully reflected in the accounts for the past year, inasmuch as the new arrangement was not completed until quite recently, but the course adopted will, it is hoped, during the current year, contribute materially towards a further appreciable reduction, both in the cost of manufacture and in the standing charges. The shareholders were informed at the last annual meeting that an understanding had been come to, subsequent to the issue of the report, with the British Electric Light Company, by which the action instituted by that Company against the Corporation was abandoned, it being admitted that the Brush machine in no way infringed the Gramme patent. A satisfactory settlement was also arrived at with Messrs. Latimer Clark, Muirhead, and Co., between whom and the Corporation cross actions were pending with regard to disputed accounts; and an arrangement has been made with the Hammond Company by which they have, for a consideration, been released from their contract to re-purchase the apparatus returned by them under the agreement referred to in the last report. The Directors regret the heavy loss sustained by the Corporation in connection with the law suit, *re* Muir and Co., reported to the shareholders in July last. The Corporation are now, however, happily not involved in any litigation, and the Directors trust that the exceptional items of law charges which have hitherto absorbed so large a proportion of the gross profits will find no place in the future profit and loss accounts of the Corporation. The Board, however, cannot but regard it as their first duty to take such steps, with a view to the maintenance and protection of the valuable patent rights of the Corporation, as may from time to time become necessary, and to exercise due vigilance in detecting and taking proceedings in respect of infringements. The Directors felt it incumbent upon them to take active steps to obtain adequate amendments in the legislation with regard to electric lighting, and early last year the Corporation directed the attention of the public to the unprecedented and exceedingly onerous conditions imposed upon electric lighting contractors by the Act of 1882, which is so largely responsible for the delay in the establishment, on a large scale, of central stations, in the absence of which the supply of electricity for house-to-house lighting cannot be economically undertaken. Later in the year a deputation to the Board of Trade was organised by the Chairman, and, as the shareholders are already aware, the interview with the President of that department was of a character to encourage the hope that a fair and reasonable proposal of reform will be favourably received by the Government. To judge from the feeling of the public, as expressed by the press, the country now generally recognises that an important industry is suffering from unduly repressive legislation. Since the time when the deputation waited upon the Board of Trade, a powerful and representative committee has been constituted to formulate, at the request and for the consideration of the Board of Trade, the views of the

Digitized by Google

electric lighting companies, and others interested in the matter, as to the nature of the amendments required. The cause of reform has also been very materially promoted by the independent action of other bodies. A very excellent report upon the subject has been drawn up and submitted to the Board of Trade by a society of electrical ennineers ; and public opinion may fairly be said to be aroused in the matter, so that it may reasonably be hoped that the injury unintentionally inflicted upon electric lighting by Parliament will speedily be remedied. The manufacture of the improved Brush armature has been systematically proceeded with, and the results obtained exceed the expectations formed regarding it. By its use the output of the Brush dynamo is increased by fully 40 per cent., and the efficiency is also very greatly increased. These new armatures are made interchangeable with the old, and no other part in the machine requires alteration. A considerable demand already exists for them, and it may be confidently expected that this demand will increase, and that every machine in use will be ultimately so fitted. The Ratchet lamp (Brush-Sellon patent) of which mention was made in last year's report, has also been well introduced, and has given complete satisfaction as an almost absolutely steady and unflickering arc lamp. The system of manufacture pursued in the case of this, as well as of the Brush lamp, is the same as that for the dynamos—namely, to secure an interchangeability of parts. At the same time the Brush lamp still holds its own as the most simple, reliable, and enduring lamp for arc lighting in exposed situations. In the incandescence department satisfactory progress has been made. The Victoria machine has fully maintained its high position as the leading machine for incandescence lighting in the market. Great improvements have been made in its armature with excellent result, and various minor but substantial improvements have also been introduced, without increasing the price, and not only has the cost of production of the machines been materially reduced by the organised system of manufacture, but the Victoria as well as the Brush dynamos are now made so that the parts of similar machines are interchangeable, thus increasing their relative value, and enabling the Corporation to sell at higher prices. Special attention is being given to the manufacture of lamps of high candle-power, and the Victoria lamp takes a prominent position amongst the best known incandescent lamps. In connection with the extension of the business of the Corporation as contractors for installation work, it became necessary to work out complete sets of fittings, for ship, factory, and private lighting, and the production and sale of these will henceforward form an important part of the business of the Corporation. The capital account has been increased by £7,992, the amount received from holders of partly paid shares in the exercise of the option given them of making their shares fully paid. The maximum number of fully-paid shares the Corporation are eventually liable to issue to the shareholders in the Great Western and Brush Midland Companies is stated in the balance sheet, but the actual amount of capital that will ultimately have to be issued is dependent upon the number of fully-paid shares in these companies that will be surrendered. The total amount owing by the Corporation to creditors and on bills payable is £3,726 6s. 4d., and as the good debts due to the Corporation amount to £19,560 16s. 8d., and the cash at their credit with the bankers and in hand stands at £10,541 4s. 2d., the satisfactory position of the Corporation will be at once realised by the shareholders and the public. The amount of the provision against shares held by the Corporation in subsidiary companies has been reduced from £99,200 to £50,000, the shares of the Brush Midland Electric Light Company, Great Western Electric Light Company, and Eastern Electric Light Company, having been eliminated from the contra account, owing to these companies being now in voluntary liquidation. The patents account shows an increase of £3,676 12s. 11d. upon last year's valuation. This increase represents the cost of maintaining the English and foreign patents, and of the experiments and other initial steps necessary to obtaining patent protection for the several inventions which have been developed in connection with the advance made by the Corporation in the various branches of its manufacture, and in introducing the new machines and apparatus. Under the head of appropriation of profits, the Directors recommend the reduction of patents account by the amount of £1,500 as a matter of principle, and not because they believe that there is anything either in the present aspect of affairs or in the general progress of electric lighting to call for a depreciation of the value of the patents possessed by the Corporation. The events of the year have really tended to increase the intrinsic value of these patent rights, and the Board are of opinion that the figure at which this asset stands in the books represents its minimum value. As a result of the concentration of the manufacturing arrangements, a considerable amount of the plant, fixed and otherwise, at the Borough-road and Portpool-lane premises, has been consigned to stock, and will be further employed or eventually realised as opportunity offers. It has consequently been deemed advisable to have a careful revaluation and readjustment made of the property and stock accounts, the result being to reduce the property account to £40,147 9s 6d., and to increase stock account to £69,171 11s. 1d., the latter figure representing the minimum cost value of the stock on hand, stores, and goods in course of manufacture. In view of the extremely low figure at which property stands in the books, and having regard to the increased efficiency resulting from the concentration of the works, it is not thought necessary to make any reduction this year in respect of depreciation. The amount of £413 7s. 4d. representing premiums on insurance, rent, &c., paid in advance on account of 1885, and not therefore chargeable against last year's revenue, has been carried to a suspense account. The item "Assets Realisation Accounts £29,475" represents the gross value of the assets to be transferred from the Great Western and Brush Midland Companies, in addition to the £4,000 cash which has been already received. The absorption of these companies was not effected in time to enable the various assets to be incorporated in the books of the Corporation under their respective heads, but it is estimated that when the liquidation of these companies has been closed, the undermentioned accounts will be increased as follows :—

Property Account.—By the value of plant at lighting stations, installations on hire, freehold and leasehold land and buildings, &c. £12,700
Stock Account.—By the value of manufactured goods on hand 4,000
Cssh (in addition to the £4,000 already received) 6,800
Patents Account.—By balance representing goodwill and surrender of Brush and Lane-Fox licenses for twenty-eight counties in England and Wales..... 5,975

In addition to the above-mentioned assets, the Corporation, as shareholders, have received from the Great Western Company £1,000. This amount has been carried to credit of profit and loss account, and will be dealt with in the appropriation of the net balance of profit. It will be seen from the profit and loss account that the result of the year's operations is a gross profit of £22,948 10s. 3d., including profit on shares in Great Western Company, proceeds of sale of patents and bad debts recovered, less provision for doubtful debts, and that after deducting all standing charges and expenses, there remains a surplus profit on the year's working of £5,743 18s. 6d., notwithstanding the heavy loss attendant upon the Muir lawsuit, and after charging sundry items more properly belonging to the previous year. From this profit, however, has to be deducted the adverse balance of £1,616 3s. 2d. brought forward from last year, leaving, as the available result of all the transactions of the past year, a net surplus profit of £4,127 15s. 4d. An analysis of this profit and loss account will show, not only a very marked improvement in the business effected, both as regards its volume and its profitable character, but also that the efforts of the Board to economise in every department have been, in a very high degree, successful. Comparison with the operations of the previous year shows that the gross actual trading profit has increased by nearly 120 per cent., while the standing charges have been reduced by more than 45 per cent. The Directors recommend, that of the amount standing to credit of profit and loss account—£1,000, being the sum received in respect of the shares of the Great Western Company—be applied to reduction of the cost of goodwill and licenses, that £1,500 be applied to the reduction of patents account, as explained above, and that the remainder, amounting to £1,627 15s. 4d., be carried forward to next account. The Directors who retire by rotation are Mr. Gibbs, Mr. Courtenay, and Mr. Ladd, who, being duly qualified, offer themselves for re-election. The Directors have pleasure in announcing that Mr. Joseph Bevan Braithwaite, jun., a member of the firm of Messrs. Foster and Braithwaite, and late chairman of the Great Western Electric Light Company, has, at the invitation of the Board, expressed his willingness to join the directorate, but as the Board are not empowered, under the Articles, to appoint an additional Director, they nominate Mr. Braithwaite for election by the shareholders. Messrs. Cooper Brothers and Co., the auditors, retire, and offer themselves for re-election.

NOTES.

DIRECT UNITED STATES CABLE.—We notice that this cable is interrupted.

SOUTH AFRICAN CABLE.—This cable is interrupted between Zanzibar and Mozambique.

THE TELEPHONE IN AMERICA.—Oral communication may now be held by telephone between New York and Boston.

INVENTORIES.—We understand that Messrs. Siemens are to light up the grounds of the forthcoming exhibition by the electric light.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 30th January amounted to £3,668.

ANTWERP EXHIBITION.—The Belgian Chamber of representatives has voted a subsidy of 500,000f. (£20,000) in aid of the Antwerp Exhibition of this year.

BERNSTEIN ELECTRIC LAMP COMPANY.—We understand that this company will have the lighting of the dining rooms at the forthcoming Inventions Exhibition.

DUBUQUE, OHIO.—The electric light companies of this town have been compelled to stop work because of the constant losses, there not being sufficient demand for the light.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of January, 1885, amounted to £57,249, and to £55,503 in the corresponding period of 1884.

PERSONAL.—We hear that Mr. J. F. Albright, late engineer to the Edison-Swan Company, has resigned his appointment, and entered into partnership with Messrs. R. E. Crompton and Co.

THE TELEPHONE IN ROME.—The subscribers have appointed a committee for protesting against the yearly rate being increased from 100 to 180 lire (£4 to £7 4s.) as the company proposes.

INVERNESS.—The New Central Telephone Exchange was opened on 19th January, the first call being received at 10 o'clock; and about two hundred messages were transmitted during the day.

GAS AND ELECTRIC LIGHT COMBINATION.—At Evansville, Ind., U.S.A., the Electric Light Company has lately been fused with the Gas Company, so that either light is available for customers.

THE ELECTRIC LIGHT IN BANKS.—Last week the lighting arrangements for the Crédit Foncier, including 100 incandescent lamps, installed by the Paris Edison Company, were brought into use.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of January, 1885, amounted to £1,770, against £2,072 in the corresponding period of last year.

COMPAGNIE INTERNATIONALE DES TELEPHONES.—The 375fr. (£15) paid-up shares of this company rose from par on 26th January, to 382fr. 50c. on 2nd February, showing an advance of 7fr. 50c., or about 6s.

ELECTRICAL COMPANIES IN AMERICA.—It is reported that in the week ending December 13, eleven new corporations for electrical purposes were organised in the United States, with an aggregate capital of $1,900,000.

SNOW AND LIGHTNING IN ITALY.—Notwithstanding the fact that railways were blocked and telegraph lines interrupted owing to the recent snow storms, two peasants were struck by lightning at Corigliano, near Naples.

SHIP LIGHTING.—The Paris Edison Company has lighted the Transatlantic Company's steamer "Labrador," beginning the installation on 19th, and completing it by 24th January, when the steamer left for New York.

PARIS ELECTRICAL EXHIBITION.—The Exhibition organised by the Société Internationale des Electriciens, at the Paris Observatory, with the co-operation of Admiral Mouchez, is announced to open on Sunday, 15th March.

AND SO SAY ALL OF US.—Sig. G. de Franceschi, in a note on the watt and volt-ampere published by *Il Giorno*, thinks it highly desirable that the next Electrical Congress settle, once for all, the electrical units and nomenclature.

BUSINESS.—Messrs. Paterson and Cooper, European Telegraph Works, Dalston, have added a department to their works for the extensive manufacture and supply of every article required for the electro-deposition of various metals.

MADRID EXHIBITION, 1886.—A Spanish Royal decree, dated 9th January, enacts that an international exhibition of art and industry be held in the park of Madrid next year, the arrangements being left to an organising committee.

BRIGHTON ELECTRIC RAILWAY.—During the six months that this line has been working, the distance run by the cars has amounted to 15,600 miles, and 200,000 passengers have been carried, the total cost of traction being less than twopence a mile.

CANTOR LECTURES.—Professor Forbes gave the first of his Cantor lectures on the distribution of electricity, on Monday evening last, at the Society of Arts. We hope in due course, with the permission of the society, to give these lectures in full.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 30th January were £2,916, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

CARRE CARBONS.—We understand from Messrs. Thompson, Dowsing, and Rew, the agents in this country, that M. F. Carré, the well-known carbon manufacturer, of Paris, has taken out patents for improvements in carbons, which are manufactured by Emile Levy, of Paris.

SUGAR REFINING.—A new process was recently tried in America for sugar refining, in which the principal agent employed is electricity. The cost is said to be not more than 3s. 4d. per ton, and the result a hard sugar of almost absolute purity without any syrup whatever.

CHURCH STRUCK BY LIGHTNING.—A heavy thunderstorm visited Winchester on Saturday afternoon, when the electric fluid, descending, it is said, like a ball of fire, struck the tower of St. Cross Church. The oak shaft was shattered, one of the brethren's houses being also stricken.

ELECTRO-MAGNETIC PHENOMENA OF THE POLARISATION OF LIGHT.—The Science Class of the Belgian Royal Academy has accepted a sealed paper by M. van Aubel, of Liége, dealing with his researches on the electro-magnetic rotation of the plane of polarisation of light and similar phenomena.

THE ENGLISH ILLUSTRATED MAGAZINE.—We have received the February number of this magazine, in which there is no diminution in the beauty of the illustrations or in the value of the letterpress. It shows that the art of illustrating is not so completely lost in England as has been imagined.

Digitized by Google

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of January, 1885 (including Government subsidies), amounted to £44,144, and to £41,129 in the corresponding period of 1884, showing an increase of £3,015.

ELECTRICITY AND MAGNETISM.—"The action at a distance of a short closed circuit is equal to that of a short magnet placed at right angles to the plane of the circuit; and the moment will equal the product of the circuit-bounded area by the intensity of the current."—R. Ferrini (*Elettricità e Magnetismo*).

ELECTRIC LIGHT IN THE THEATRE.—The Edison lamps placed in the lustre of the Paris Opera are said to give excellent results, and to have induced the management to adopt the electric light for the approaching *bals masqués*. The dynamos work almost uninterruptedly from Friday evening to Sunday morning.

E.M.F. DEVELOPED BY LUMINOUS RAYS.—At a recent meeting of the Paris Academy of Science, M. F. Griveaux handed in a note on the results furnished by Clarke's potentiometer, applied to the measure of electromotive force developed by the action of luminous rays on a silver plate covered with salts of silver.

SOUTH OF ENGLAND TELEPHONE COMPANY.—This "limited" company, which has been formed for working and developing electrical business, and specially for carrying out an agreement made with the United Telephone Company, for telephone working, is now issuing 20,000 £6 per cent. first preference shares of £5 each.

RAILWAY STATION LIGHTING.—The French Eastern Railway Company has decided to light the platforms and waiting rooms of the Paris terminus by 9 arc and 60 incandescent lamps, to be installed by Siemens Brothers, of Paris. The Epernay station of the same company is being fitted with 20 arc lamps by the Maison Breguet.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of January was 3,556, estimated to produce £3,000, against 3,291 messages, producing £3,009 in the corresponding month of last year. The traffic receipts for the month of October, estimated at £2,200, realised £2,230.

THE SOCIETY OF TELEGRAPH ENGINEERS.—At the meeting of the society on Thursday, February 12, at 8 p.m., Captain H. R. Sankey, R.E., will deliver a lecture on "Some Experiments in Electrotyping with a Dynamo-Electric Machine;" and I. A. Timmis, M.I.M.E., will lecture on "The Working of Railway Signals and Points by Electro-Magnets."

THE OMNIPOTENT "I."—Last week an eminent firm of electric light engineers received a letter from a gentleman worded thus: "Please let me know how it is that electric light companies are handicapped by the Acts, so that I may take steps to alter this." This letter is evidently written in sober earnest, as the writer gives his full name and address.

"INDUSTRIAL AMERICA."—This is the title of a new illustrated contemporary, published at the offices of the *Electrical World*. It seems to be intended to follow somewhat in the footsteps of the *Scientific American*, but in order to compete successfully with its rival, its illustrations will have to be made for the sake of giving information and not for the sake of making its pages look pretty.

PERSONAL.—Mr. John D. Miller, formerly district manager at Greenock to the National Telephone Company, has been promoted from the office of district manager at Aberdeen, to that of manager of the Dundee and District Exchanges, with nearly 700 subscribers, and branch exchanges at Broughty Ferry, Newport, Tayport, Forfar, and Perth, while others are to be formed at Arbroath and Montrose.

THE CREIL EXPERIMENTS.—These experiments, which were to have begun in January, have been delayed by the late hard frost, which prevented the erection of the posts for carrying the cable, and also rendered brittle the insulating substance with which the latter was to be covered, as a prudential measure. The machines have been erected under the supervision of M. Marcel Deprez, who is said to guard them with the greatest jealousy.

AT HOME OR NOT.—The story is well known of a country servant who told a caller that her mistress said she was not at home. They now manage these things better on the Continent by the aid of electricity. The visitor presents his card to the *concierge*, who telegraphs the name to the *locataire*, or occupier of the apartment, if he is within, and receives back a sign, only visible to himself, denoting whether he will "receive," or not be bothered.

"THE GENIUS OF PROGRESS."—This is the title of a painting by Herr Ludwig Kandler, who has incorporated the realistic and the allegorical in a beautiful female figure with incandescent lamps set as a coronet on her brow, holding aloft in her right hand an arc light as beacon, with the battery in her left, while two attendant cherubs are holding discourse by means of the telephone. The picture is admirably reproduced in this week's *Sporting and Dramatic News*.

ELECTRIC LIGHT FOR HACKNEY.—Several of the larger tradesmen in Hackney are anxious to light their premises by electric lamps, to be supplied by the Jarman Company, whose works are at Homerton. Permission has been applied for to lay pipes from the factory to Mare-street; and the Board of Works has referred the subject to a committee. The Jarman Company has lighted some works at Glasgow, and also the Atlantic Wharf, while it is preparing the plant for lighting the town of Deal.

"THE "AQUIDABAN."—The electric lighting apparatus for the Brazilian ironclad "Aquidaban," which has been recently launched from Messrs. Samuda's yard, is to consist of three sets of direct-driven steam dynamos. Each set is composed of a new pattern Crompton dynamo, driven by a Willans high-speed compound three-cylinder engine. There are to be 250 incandescent lights fitted all over the ship, in addition to two projectors for search-light purposes. The whole of the work is being carried out by Messrs. R. E. Crompton and Co.

AN ELECTRICAL TRAMCAR.—At the Wandsworth Board of Works the following motion has been made with regard to the proposed running of an electrical tramcar:—"That before the consent of the Board be given to the proposal to run electric cars on the tramways, the opinion of an independent engineer or expert be taken, and that the engineer engaged do attend the General Purposes Committee on their visit to inspect the said cars, the fee and expenses of the engineer not to exceed the sum of £10 10s., and such fee and expenses to be paid to this Board by the parties making the application."

HARROW.—The lighting of the Harrow School laundry, which had for some time been carried out by means of two A Gramme machines and Serrin lamps, has recently been entirely changed. The old installation has been completely removed, and a new one put up by Messrs. R. E. Crompton

Digitized by Google

and Co., consisting of a Crompton-Bürgin machine and incandescent lamps. We understand that the masters, and all connected with the laundry, are very much pleased with the new lighting, and the work as carried out is a credit to the contractors.

NEW COMPANY.—The Compagnie de Signaux Magnétiques et Communications Téléphoniques has been founded at Paris, with a capital of 1,250,000f. (£50,000), in 2,500 shares of 500f. (£20) each for exploiting, in all countries of the world, magnetic signals and telephonic communications, especially the patent of Bruno Abdank Abakanowics. The promoters are M. Adrien Hebrard and M. Cornélius Herz, who each received 100 paid-up shares. The above named, with M. Marcel Bernstein, M. Amédée Bocher, and M. Emile Leclert, form the council of administration—that is to say, the board of directors.

PRIZE FOR TREATISE ON THE DYNAMO.—The Real Academia de Ciencias exactas, fisicas y naturales of Madrid offers prizes consisting of gold medals weighing 60 grammes (nearly 2oz.), besides *accessits* and hon. mentions, for the best paper on three subjects, including one on the mathematical theory of magneto-electric and dynamo-electric machines, especially those based upon the Gramme machine, including induction and practical applications. Papers for competition are to be sent in by 31st December, 1866; and foreigners as well as natives of Spain are admitted to compete, members of the Academy being alone excepted.

LONG-DISTANCE TELEPHONY IN FRANCE.—The *Journal Officiel* of the French Republic has notified that from 16th January long-distance telephone communication has been afforded between Rouen and Havre by means of the telegraph wires connecting the two cities. The fee is 1f. for five minutes' conversation; and communications may be made between public call offices in the waiting rooms and post-office at Rouen and the central telegraph office at Havre. Other call offices are to be opened shortly; and telephone subscribers may hold converse from their own houses, on the same terms, as soon as certain modifications have been made in their instruments.

ELECTRIC LIGHT IN PARIS.—Among the few electric lighting installations which have been preserved in the public thoroughfares of Paris, that of the Place du Carrousel is among the most noteworthy. Ten tall candelabra, curved at the top, carry pulleys on which work the cords for suspending the Lontin lamps. Both the cords and the conductors are wound on a winch for raising the lamps to a height of eight metres, or 26ft. Two other lamps, on the Mersanne principle, with horizontal carbons, are mounted on a central column at a height of 20 metres, or 65ft. All the lamps are provided with reflectors, which throw the rays downwards. The dynamos, driven by a 35 horse-power steam engine, are placed in a temporary pavilion.

THE TELEPHONE IN A TUNIS SHRINE.—*The Times* Paris correspondent has sent the "Thunderer" an amusing account of the application of the telephone to a Kouba, or shrine, in the environs of the holy city Kairwan, the keeper of which is of French origin and a seceder from the Roman faith. His revenues being small, it struck him that a telephone might render him real service, so he decided to instal one in the Kouba, which will convey to him in his chamber the questions put to the saint, and return his own replies. Besides the material advantages which this mode of performing his ministry might bring him, he knows that he will produce a deep and salutary impression on the minds of the faithful, for whom the *modus operandi* will long remain a dread mystery.

ITALIAN TELEGRAPHS.—It appears from an official return by Cavaliere E. D'Amico, director-general of telegraphs in Italy, that in 1883 the total length of the lines was 28,506 kilometres (17,712 miles), with 97,136 kilometres (60,358 miles) of wire, showing an increase, as compared with 1882, of 893 kilometres (555 miles) of line and 3,417 kilometres (2,122 miles) of wire. During 1883, 147 new offices were opened, bringing up the number to 2,737, with 2,932 instruments. The number of telegrams, inland and foreign, was 7,176,523, showing an increase of 124,302 over that of the preceding year. The receipts amounted to 10,971,741 lire (£438,869), and the expenses to 9,190,433 lire (£367,617), giving a net profit of 1,781,308 lire (£71,252), while the Government messages were sent free of charge.

ELECTRICAL STORAGE.—Mr. Eric Bruce, in his lectures upon the electric light, says that, for private house lighting purposes, the storage of energy is almost indispensable. If a dynamo machine only is used, the lights could only be maintained when the machine is working; but, if the energy could be stored, the lights would be available at any time. Many persons now used the electric light in their houses, and even in bed rooms as a night light which they could turn on and off at any time, simply because they had an accumulator. He had used an accumulator four or five weeks, during which time it was only charged twice or thrice, and there was not a single breakdown. The lecturer explained by means of experiments the construction and working of a storage battery, and illustrated the principle by burning portions of magnesium wire.

THE SS. "TAINUI."—This fine ship, built by Messrs. Denny Brothers, of Dumbarton, for Messrs. Shaw, Saville, and Albion, has been fitted with 306 Swan 20-candle lamps, fed from two Ferranti-Thompson dynamos, excited by two Siemens machines, all driven by an engine from Marshall and Sons, Gainsborough. The specification for the installation was drawn up by Professor Jamieson, of Glasgow; and the work was executed under the superintendence of Mr. R. D. Smillie, M.S.T.E., the chief electrician of Messrs. Denny Brothers, who have now an electrical department in their works. The insulation resistance of the circuit is far above the average; and great care has been taken to guard the wires from injury. The ship is wired on the system which employs the hull as a return wire. Safety fuses of "mica-foil" are inserted in every main and branch circuit.

EXPERIMENTS ON LIGHT SHIPS.—We learn that Messrs. R. E. Crompton and Co. are carrying out experiments, under the direction of Captain Graham Hills, R.N., of the Mersey Harbour Board, to test the suitability of the electric light for use on board the light ships. The set of plant for each light ship will consist of a Crompton-Bürgin dynamo, driven direct by a Willans engine, supplying current to two powerful arc lights of 4,000 candle-power each. The lamps themselves will be of the ordinary Crompton-Crabb pattern, and be fixed in the large lanterns at present in use. The beam will be diffused equally in all directions without any attempt to concentrate it by means of diaptric appliances. The whole of the generating plant is contained in a small deck house, and can be managed by the ordinary lightship keepers.

THE TELEPHONE AT STOCKPORT.—In accordance with the terms of the new license granted to telephone companies by the Postmaster-General, the Lancashire and Cheshire Telephone Exchange Company is making arrangements for the opening of

Digitized by Google

call offices, in which the public may speak to a subscriber for 3d. for three minutes in the same town, or 6d. between two towns. On wishing to speak with a subscriber, a person enters the central or a branch office, and, if the latter, he drops his 3d. or 6d. into a box which communicates automatically with the central office. The name of the person to which he wishes to speak is made known to the official at the central office, who immediately puts the parties into direct communication with each other. The automatic arrangement is such that the official knows at once whether 3d. or 6d. has been put into the box, and can thus cut off communication at the proper time.

ELECTRIC LIGHTING IN THE NAVY.—Some experiments are being made on board the "Colossus" at Portsmouth, for the purpose of ascertaining the cost of electric lighting as compared with oil, &c. A certain number of lamps are kept on from 6 to 9 p.m., when the men's lights are turned out; but the officers' are continued till 11 p.m., in the same proportion as would be observed were the ship in service. From 1 p.m. to 7 a.m. the engine and boiler rooms are to remain lighted, as well as the passages and platform and other portions of the ship guarded by the ship's police. The Brush incandescent system is adopted, maintained by three Victoria dynamos, each one capable of generating sufficient current to light the whole ship, and leaving the other two available for the search lights. Each machine is perfectly interchangeable, and the whole plant is placed well below the water line, being protected by three inches of armour. There are 380 lamps, nearly half of 20 candle-power, and the remainder 10 candle-power.

MARYLEBONE AND THE RATING OF TELEPHONE COMPANIES.—The Court of Appeal last month gave judgment in the matter of the Lancashire and Cheshire Telephone Company and the overseers of Manchester. The judgment was that "everything connected with the working of the telephones was the exclusive property of the company, for whose benefit alone they were fixed; therefore the company was rateable, and the appeal must be dismissed," and was dismissed accordingly. The chairman of the United Committee of Marylebone, St. George's, Hanover-square, and St. James, seeing this judgment, put the following questions to the overseers of Manchester, to which he received the answers appended:—1. Did the overseers, in making their assessment for Manchester, assess a certain sum on every wire belonging to the company?—No. 2. Or did they put the whole of the estimated value of the wires as one property into one sum and assess the rate on the gross value?—Yes. 3. Or did they fix a nominal rate simply to bring the company within the claimed liability to the rate?—A moderate sum of £2,000 per annum. 4. If each wire were assessed separately, or the whole were assessed in one sum at the ordinary rate upon the estimated value, how was this value ascertained?—See above. 5. In all the wires in or elevated over the streets and thoroughfares of your city, by what means do you know to whom each wire belongs, so as to assess the proper parties for the same?—Practically all are owned by the same company. Notice of appeal to the House of Lords has been given.

MONTEFIORE ELECTRICAL INSTITUTE.—M. Montefiore-Levi, Belgian Senator and head of the works at Brussels where his phosphor-bronze is produced, has taken the lead in founding an electro-technical institute annexed to the Liége University, at the same time contributing a sum of 100,000f. (£4,000) for the purchase of instruments, &c. The object of this institute, like that of the Hammond Electrical College, is to provide means for engineers, on their leaving other schools, to acquire the special knowledge which shall fit them for practice as engineer-electricians. The lectures and workshop practice are so arranged as to constitute the programme of a supplementary year of study. This comprises four courses, one on the theory of electricity and magnetism, a second on mechanical construction, a third on the transmission of signals, and a fourth on electric lighting. A two-year complete course of study for the section of electricians includes the above four courses, and in addition applied mechanics, the construction of engines, physics applied to industry, metallurgy, railways, architecture, and languages. In both sections, practical work is made more prominent than theoretical teaching, the pupils being taught to use the cold-chisel and file as well as the principles of constructive mechanism. After passing two or three months in the workshop under the direction of a skilful mechanician, they go into the laboratory, then undertake industrial experiments, and are afterwards called upon to make an independent investigation into some specific subject. For further information, application should be made to M. Trasenster, Rector of the Liége University, Belgium, who so cordially received the members of the Institution of Mechanical Engineers on their visit to Liége in 1883.

THE TELEPHONE IN PARIS.—The General Telephone Company possesses a central office, corresponding with twelve branches scattered over the city; and, with few exceptions, the communications which pass by the district office to the central, and thence to the person called, are obtained in from thirty to forty seconds, any additional delay being caused by the correspondent not replying at once. According to the most recent statistics, the number of subscribers in Paris is about 3,700, of whom 3,550 already have communication, and 150 are on the point of receiving it. The average number of calls during the winter months is 24,000 a day and 1,000 a night from 7 in the evening to 8 in the morning, which gives an average of seven calls a day per subscriber. As the subscription is 600fr. (£24) per annum, or 2fr. (1s. 7d.) for each working day, a call costs on an average 28½c. (2¾d.). No telegram is so cheap or convenient as this; and the time taken for the delivery of a telegram averages an hour, whereas communication through the telephone is almost instantaneous. The company's double wires are more than 5,000 kilometres (3,106 miles) in length, the double wire system, introduced a year ago, being one of the greatest improvements which the company has effected. Great inconvenience has been felt from induction; but at present the double wire system has been most successful. The company considers that the rent paid to the City for the use of the sewers and the 10 per cent of the gross receipts paid to the State amount to about 25 per cent. of its earnings. The 220 persons employed receive salaries averaging 150f. and 160f. (£6 and £6 8s.) a month, lunch being provided gratis. At the "call" offices, though only opened a month, there has been an average of sixty communications a day.

SPAGNOLETTI TO THE TELEGRAPH ENGINEERS.—At the ordinary general meeting of the Society of Telegraphic Engineers and Electricians, held on 22nd ult., Mr. C. E. Spagnoletti, C.E., president of 1885, delivered his inaugural address. He referred with pleasure to the increased importance of the society, urged students to take greater part in the proceedings, pointed out the advantage of the library, and hoped that a laboratory would soon be added. Having premised that he was chiefly connected with railway telegraphy, Mr. Spagnoletti only touched lightly on other electrical subjects, remarking, however, on the work afforded women by the manufacture of incandescent lamps; the present dull state of affairs he attributed to the first rush and a desire to show what it was pos-

Digitized by Google

sible to accomplish in electric lighting; the Act of 1872 was not altogether unsatisfactory, but some provisions must be modified. A good current meter was much wanted; and in the mean time charge must be made per light. The incandescent system was wholly unsuited to out-door lighting. Train lighting was an important branch, but beset with many difficulties; and electric lighting generally would not be carried out satisfactorily without accumulators. Great advance had been made in telegraphy; and it was fortunate that all the telegraphs of the kingdom were in the hands of Government, the promised reduction being likely to cause a great extension. No less than 26,000 miles of wire had been added on the railways. The use of sounders, a development of Sir Charles Bright's bell instrument, was increasing. In the Colonies the use of the quaduplex instrument was becoming greatly extended, while in the United States the English system of fast-speed working was being adopted. Though telephony progressed but slowly in this country, the line between London and Brighton showed the practicability of speaking for long distances. In London no less than 50,000 oral communications were made daily. The total length of wire in the United Kingdom was 9,000 miles, wth 7,000 instruments and 20 exchanges. The present high rental was excessive; and the Belgian system of charging a fixed sum for a conversation would be appreciated. The Van Rysselberghe system of long-distance telephony conld only be applied on a limited scale. M. Marcel Deprez' method of transmitting power had not yet given any practical result; but the telpherage system was making progress, though the carriage of goods by cars worked by accumulators was likely to prove a formidable competitor. Railway telegraphs for regulating traffic were being improved and appreciated; the use of electrical repeaters, tell tales, and locking gear was now becoming general; and a tablet system on the principle of the staff method of working was being introduced.

THE ELECTRIC LIGHT AT BERECHURCH HALL.—Mr. Octavius E. Coope writes as follows to *The Times*:—"Sir: Another year has passed since you so kindly found space in *The Times* for my last letter (vide *The Electrician*, Vol. XII., p. 269), with reference to my experience of the electrical lighting at Berechurch Hall. So many inquiries are still made to me personally that I cannot help being of opinion that a very short account of the last twelve months' working might perhaps be of even more interest to the public than the accounts I gave in my letters that appeared in *The Times* in January, 1883, and January, 1884, for the element of time has been coming into operation, and the unforeseen should have been making itself apparent. Briefly, then, the result of the last year's working has been to confirm the statements and conclusions I gave in my previous letters. The lights have given even more satisfaction, if possible. The whole of the machinery and conductors are working as well as when they were first put down. The expense is about the same as the previous year, being rather under that I should have had to pay for gas; and the light is so charming, convenient, and healthy, that after being accustomed to it one is indisposed to sit in a room lighted in any other manner. How it is that the electric light has not made greater progress in this country fills me with amazement; whereas in America the impetus has been enormous, especially with regard to arc lighting. In Montreal, Philadelphia, Buffalo, Cleveland, Chicago, St. Louis, Indianapolis, Boston, and New York, not only the principal streets but the warehouses, stores, and places of public resort are described as being brilliantly lighted by electricity. Of the Brush system only there are said to be upwards of 25,000 arc lamps in operation in the United S tates; and in New York the Edison central station alone supplies current for over 12,000 incandescent lights and yet cannot come up to the demand; and it intended to open two more central stations of much larger size. So far as our own towns are concerned, the almost entire absence of the electric light I think may be explainable, but as to country houses the case is different. With regard to these latter, is it that the owners imagine by delaying they will be able to take advantage of some great discovery and get the electric light for a tithe of what they would now have to pay? Let me assure them of this, that if I had to light Berechurch Hall afresh to-morrow I would have the installation laid out again in exactly the same manner; and the cost would be almost as much as in the spring of 1882. And, again, I am just as able to take advantage of any great improvement—which to my mind will come in the form of more economical incandescent lamps or more perfect accumulators—as those who are having an installation laid down to-day. With regard to accumulators, there has been within the last year a marked improvement, and I trust before long I may see my way to use them. As to incandescent lamps, I find that the life of the ones I use (the Swan) is continually lengthening; there is, however, a new incandescent lamp in the market, one that is said to give out as much light as those I have and requires but three-quarters of the current; so I am about to give them a rigorous trial, and if I find the statements correct adopt them, for it will enable me to put up over fifty fresh lights in various buildings and run them without any addition to my machinery or increase of cost in my annual working expenses, except, of course, for lamp renewals. To revert to our towns, there appears to have been a certain amount of friction between the electric light companies and the Board of Trade. This is radically wrong, and I can see no reason why it should not be completely overcome. It is possible that there may have been faults on both sides; but it is obvious that such grand-motherly legislation as clause 27 in the Electric Lighting Act must injure private enterprise and prove detrimental to the interests of the public. By the 27th clause every public installation is practically confiscated to the local authorities after twenty-one years, should they desire to possess it, which they assuredly would do if it were paying anything like a dividend; if it were not, they have only to wait a few years until it is a success and then claim it as their property, the amount they have to pay being a mere nominal one compared to the original cost of the installation. Anything more harsh or more unjust to a new industry it is impossible to conceive. Any clause framed with the deliberate intention of preventing capital being embarked could not possibly have been more ingeniously drawn up. This modern tendency to place legislative restrictions on new enterprises to such an extent as to almost throttle them is to me perfectly incomprehensible, and to my mind entirely opposed to all that has made England foremost in the world. So succcessful has it been with the telephone that, instead of now being in the hands of even the poorest artisan, it can only be used by the few who can afford to pay an exorbitant annual sum for the privilege. If the same principles had been in vogue with regard to railways and gas, we should still be travelling in coaches in streets lighted by oil lamps. Perhaps I may again be allowed to repeat that I am entirely unconnected with any electrical company or interest of any kind whatsoever, either directly or indirectly. My sole object has been to try and work out for myself the question as to the applicability of electricity for domestic uses, which I have succeeded in doing to my entire satisfaction; and I now have the pleasure for the third time of giving the result of my experience to the public through your kind courtesy."

ALTERNATING CURRENTS.—MUTUAL-INDUCTION. GRAPHIC REPRESENTATION.

BY THOMAS H. BLAKESLEY, M.A., M. INST. C.E.

(CONTINUED FROM PAGE 200.)

MISPRINT.—In *The Electrician*, No. 10, Vol. XIV., January 17, 1885, "Alternating Currents," p. 199, column 2, line 34, for "converging" read "conveying."

For the sake of brevity it will be well to describe a magnitude undergoing harmonic variation by its maximum value. Thus, suppose in Fig. 1 B D, the projection of a constant line, A B, upon the axis of y, to represent the electromotive force at some instant acting through a circuit, and that the electromotive force undergoes the variations which this projection undergoes, it will be convenient to describe the electromotive force by its maximum value A B.

And similarly with currents. If a current is represented always by the projection of the magnitude representing its maximum, we may talk of the maximum value as the current.

Language based upon this convenient mode of expression has, in fact, been used towards the close of the previous article. We may employ the first proposition there given to the determination of the reading of a dynamometer subjected to alternating currents.

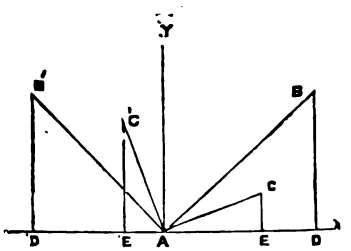

FIG. 1

Suppose, in Fig. 1, that A B represents the current through one of the coils of the dynamometer, and that A C represents the current through the other coil. Then the average value of the product of these currents will be $\frac{A C \, A B}{2} \cos B A C$.

But it is the average value of the product of these currents which will be proportional to the reading of the instrument.

Moreover, in an ordinary case the currents in the two coils are identical in value and coincident in phase.

The first consideration requires A B to be equal to A C, and we may take c as the value of each of them. The second consideration requires cos B A C to be equal to unity, since B A C = 0.

Therefore, the reading of the dynamometer will be proportional to $\frac{c^2}{2}$.

Thus the reading of the instrument which is produced by an alternating current c (*i.e.*, whose maximum is c) will be produced by a uniform current whose value is $\frac{c}{\sqrt{2}}$ or ·707 c.

The method of compounding the electromotive forces acting in one circuit and having the same period, but differing in phase, after the manner of forces and velocities in mechanics, is evidently true when we consider that the real electromotive force is the sum of the projections of each, individually projected, upon one straight line.

The graphic diagram resulting from the application of this method may be advantageously employed in exhibiting the effects of an alternating E.M.F. acting on a circuit possessing, besides self-induction, mutual induction on and from another circuit possessing self-induction in its turn.

Let L be the self-induction coefficient of the primary circuit.

Let L′ be the self-induction coefficient of the secondary circuit.

Let R and r be the resistances respectively of these two circuits, and

M the coefficient of mutual induction between them.

Take a line C F of magnitude h and draw C E at right angles to C F, and in magnitude equal to $\frac{M\pi}{RT}h$, so that, in fact, $\frac{M\pi}{RT} = \tan C F E$. On C E as diameter describe a semi-circle on the side remote from C F, and set off the angle E C A, whose tangent is equal to $\frac{L'\pi}{rT}$. From F draw F B perpendicular to A C produced, and produce B F towards F to G, so that $F G = \frac{M\pi}{rT} A C$. In C E take C D, so that C D bears to C E the same proportion which L bears to M. Join D G, and call it e.

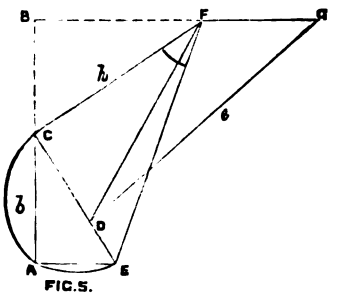

FIG. 5.

Then if e is the impressed electromotive force in the primary circuit, in phase and magnitude, C F or h will be the effective electromotive force in the primary circuit, and C A, which call f, the effective electromotive force in the secondary circuit, in phase and magnitude. In other words, dynamometers inserted in these two circuits will give the same reading as if the *constant* E.M.F.'s $\frac{h}{\sqrt{2}}$ and $\frac{f}{\sqrt{2}}$ were inserted in the circuits respectively, the angles of torsion being proportional to the squares of these lines C F A C respectively.

If we write

$$\tan\alpha = \frac{L\pi}{RT},$$

$$\tan\beta = \frac{L'\pi}{rT},$$

$$\tan\gamma = \frac{M\pi}{rT},$$

$$\tan\delta = \frac{M\pi}{RT},$$

then C F D = α, A C E = β, C F E = δ, and from the geometry of the figure we have

$$\left.\begin{aligned} f &= h\cos\beta\tan\delta \\ e^2 &= f^2\tan^2\gamma + \frac{h^2}{\cos^2\alpha} + 2fh\frac{\tan\gamma\cos\overline{\beta+\alpha}}{\cos\alpha} \end{aligned}\right\}.$$

Therefore we have for the equation connecting e and h

$$e^2 = \frac{h^2}{\cos^2\alpha}\{1 + \cos^2\alpha\cos^2\beta\tan^2\gamma\tan^2\delta + 2\cos\alpha\cos\beta\tan\gamma\tan\delta\cos\overline{\alpha+\beta}\},$$

and for the equation connecting e and f

$$e^2 = \frac{f^2}{\cos^2\alpha\cos^2\beta\tan^2\delta}\{1 + \cos^2\alpha\cos^2\beta\tan^2\gamma\tan^2\delta + 2\cos\alpha\cos\beta\tan\gamma\tan\delta\cos\overline{\alpha+\beta}\}.$$

If we write $\tan\phi$ for $\cos\alpha\cos\beta\tan\gamma\tan\delta$, for brevity's sake, these equations become :—

$$e^2 = \frac{h^2}{\cos^2\alpha\cos^2\phi}\{1 + \sin 2\phi\cos\overline{\alpha+\beta}\},$$

$$e^2 = \frac{f^2\tan^2\gamma}{\sin^2\phi}\{1 + \sin 2\phi\cos\overline{\alpha+\beta}\};$$

Digitized by Google

or, to express the effective electromotive forces separately in terms of e,

$$h = \frac{e \cos \alpha \cos \phi}{\sqrt{1 + \sin 2\phi \cos \overline{\alpha + \beta}}},$$

$$f = \frac{e \sin \phi \cot \gamma}{\sqrt{1 + \sin 2\phi \cos \overline{\alpha + \beta}}},$$

whence the expressions for the currents $\frac{h}{R}$ and $\frac{f}{r}$, in terms of the coefficients of self and mutual induction, the resistances and the period, become, by the proper substitutions

$$\frac{h}{R} = \frac{e\,T\,(r^2\,T^2 + L'^2\,\pi^2)^{\frac{1}{2}}}{\{(M^2\,\pi^2 + R\,r\,T^2 - L\,L'\,\pi^2)^2 + \pi^2\,T^2\,(L\,r + L'\,R)^2\}^{\frac{1}{2}}} \cdot \quad (\alpha)$$

$$\frac{f}{r} = \frac{e\,T\,M\,\pi}{\{(M^2\,\pi^2 + R\,r\,T^2 - L\,L'\,\pi^2)^2 + \pi^2\,T^2\,(L\,r + L'\,R)^2\}^{\frac{1}{2}}} \cdot \quad (\beta)$$

The relation which the current in the secondary coil bears to that in the primary is simply

$$\frac{M\,\pi}{(r^2\,T^2 + L'^2\,\pi^2)^{\frac{1}{2}}} \cdot \cdot \cdot \cdot \cdot \cdot \cdot \quad (\gamma)$$

and the relation of the dynamometer readings in the two circuits will be as the square of this expression.

(TO BE CONTINUED.)

ON THE DESIGN AND CONSTRUCTION OF DYNAMOS.

BY GISBERT KAPP.

At various times letters have appeared in the pages of *The Electrician* either asking for information how to construct a particular dynamo or setting forth unexpected difficulties or failures encountered by amateurs who tried to make small machines. Now, it would of course be very easy to compress into the space of a short article a few empirical rules which any amateur could faithfully follow, and thus construct a dynamo which will work more or less successfully. But this would hardly be satisfactory from a scientific point of view. It is not sufficient if we know how to make one particular kind of machine so that it will work; we must also know the why and wherefore of its performance, so as to be able to generalise from a few practical examples to all possible varieties of machines of the same kind. As regards dynamos, this knowledge is as yet very meagre. Let us at once confess that we cannot calculate with mathematical precision the best size, shape, and existing power of a pair of field-magnets, or the exact speed at which a given machine must run to produce a certain electrical output, unless we have previously made trials with similar magnets and machines. But worse than this, if we attempt a mathematical treatment on the basis of our standard text books, we are sometimes led to results utterly at variance with the outcome of practical experience. To cite only one case. According to Lenz, Jacobi, Dub, Müller, and others, the magnetic moment of cylindrical electro-magnets is for low exciting powers proportional to the exciting power, and also proportional to the square root of the diameter and to the square root of the third power of the length. The practical application of this law is simple enough; to obtain a maximum of magnetic moment with a minimum of iron and copper wire, it is best to make the magnets thin and long. This has actually been done in the original Edison machine, and after it was done and everybody had admired the beautiful application of a great scientific principle, Dr. Hopkinson doubled the output of the Edison machine by simply employing shorter and thicker magnets. In this case it would seem as if science had been positively misleading; but this was of course not so. It was not Dub's law which was at fault, but its application to a form of magnet for which its author had never intended it.

But although mathematical investigations have as yet not taught us how to design every detail of a dynamo with the same certainty of result as a civil engineer might design every strut and beam in an iron bridge, very good machines are daily being built by many dynamo makers in this country, who simply base their designs on experiments, assisted by mechanical instinct and a little, a very little, scientific calculation. For the rest, this is the course every new industry takes. The first makers of steam engines knew nothing of the mechanical theory of heat, and yet they made fairly good engines long before Joule, Clausius, Rankine, and Zeuner showed us how to make excellent engines. A similar improvement may be looked for in dynamos and motors; but until scientific men can show us the way we must be content to work and improve the machines as we are doing now, which, taking all things into consideration, is at a fairly good rate.

In the following a few simple rules are given for the design of dynamos, but in order not to fall into the error of mere rule of thumb practice it will be necessary to preface them by a few general considerations and principles on which such rules are based. So much has been written on the subject of dynamos and the principles which underlie their action, that many well-known things will have to be said here over again; but it is better to sin by repetition than to make the subject more difficult than it already is by omitting important first principles.

The interaction between an electric current and a magnet can most conveniently be considered by the conception of lines of force. Whether such lines do really exist or not does not concern us at present. For our purpose it suffices that by means of iron filings we can make such lines visible and study their properties. According to this conception every wire carrying a current is surrounded by a multitude of circular lines packed closely together in the immediate neighbourhood of the wire and more sparsely at a distance from it. If we could have a free magnet pole—that is, a piece of steel having only one polarity, say north, for instance—this pole would, if brought near the wire, revolve round it; but since a magnet with only one pole is an impossibility, and since the same force which urges the north pole in one direction will urge the south pole in the opposite direction, the magnet as a whole cannot revolve round the straight wire, but will set itself at right angles to it. Which way the lines of force run round the wire we cannot say, but to fix ideas we shall consider those lines positive which would carry a N pole round the wire in the direction of the hands of a watch if the observer sees the wire end on, and if the current flows from the observer. If we place a piece of paper over the magnet, and at right angles to the wire, the lines of force made visible by iron filings will now appear as somewhat distorted circles crowding densely into the poles of the magnet. Within the magnet they are not so well defined as outside it; but as near as can be judged from a rough experiment no lines are lost in the middle, and the same number of lines which enter at one side of the magnet find their way out at the other. This follows also from the consideration that we cannot have one free magnetic pole or a magnet with unequal poles. From this it will be seen that every line of force must be a closed line; an open magnetic line of force—that is a line with two ends—is as much an impossibility as a continuous current in an open circuit. According to our nomenclature, the positive line of force goes in air from N to S, and in iron from S to N. If, instead of a steel magnet, we had experimented with a piece of soft iron, we would also find that through its presence the originally circular lines round the wire have become somewhat distorted and crowded together at the ends of the piece of iron, which, like a steel magnet, will set itself at right angles to the straight wire. The total number of lines made visible by filings has been considerably increased, even on the side of the wire opposite to that where the piece of iron is placed; and if we increase the current we can still further increase the number of lines. This experiment, therefore, shows that the number of lines, other things being equal, depends on the strength of the current, and that one and the same current will yield more lines if a piece of soft iron be placed in its neighbourhood. It also shows that the lines pass more easily through iron than through air.

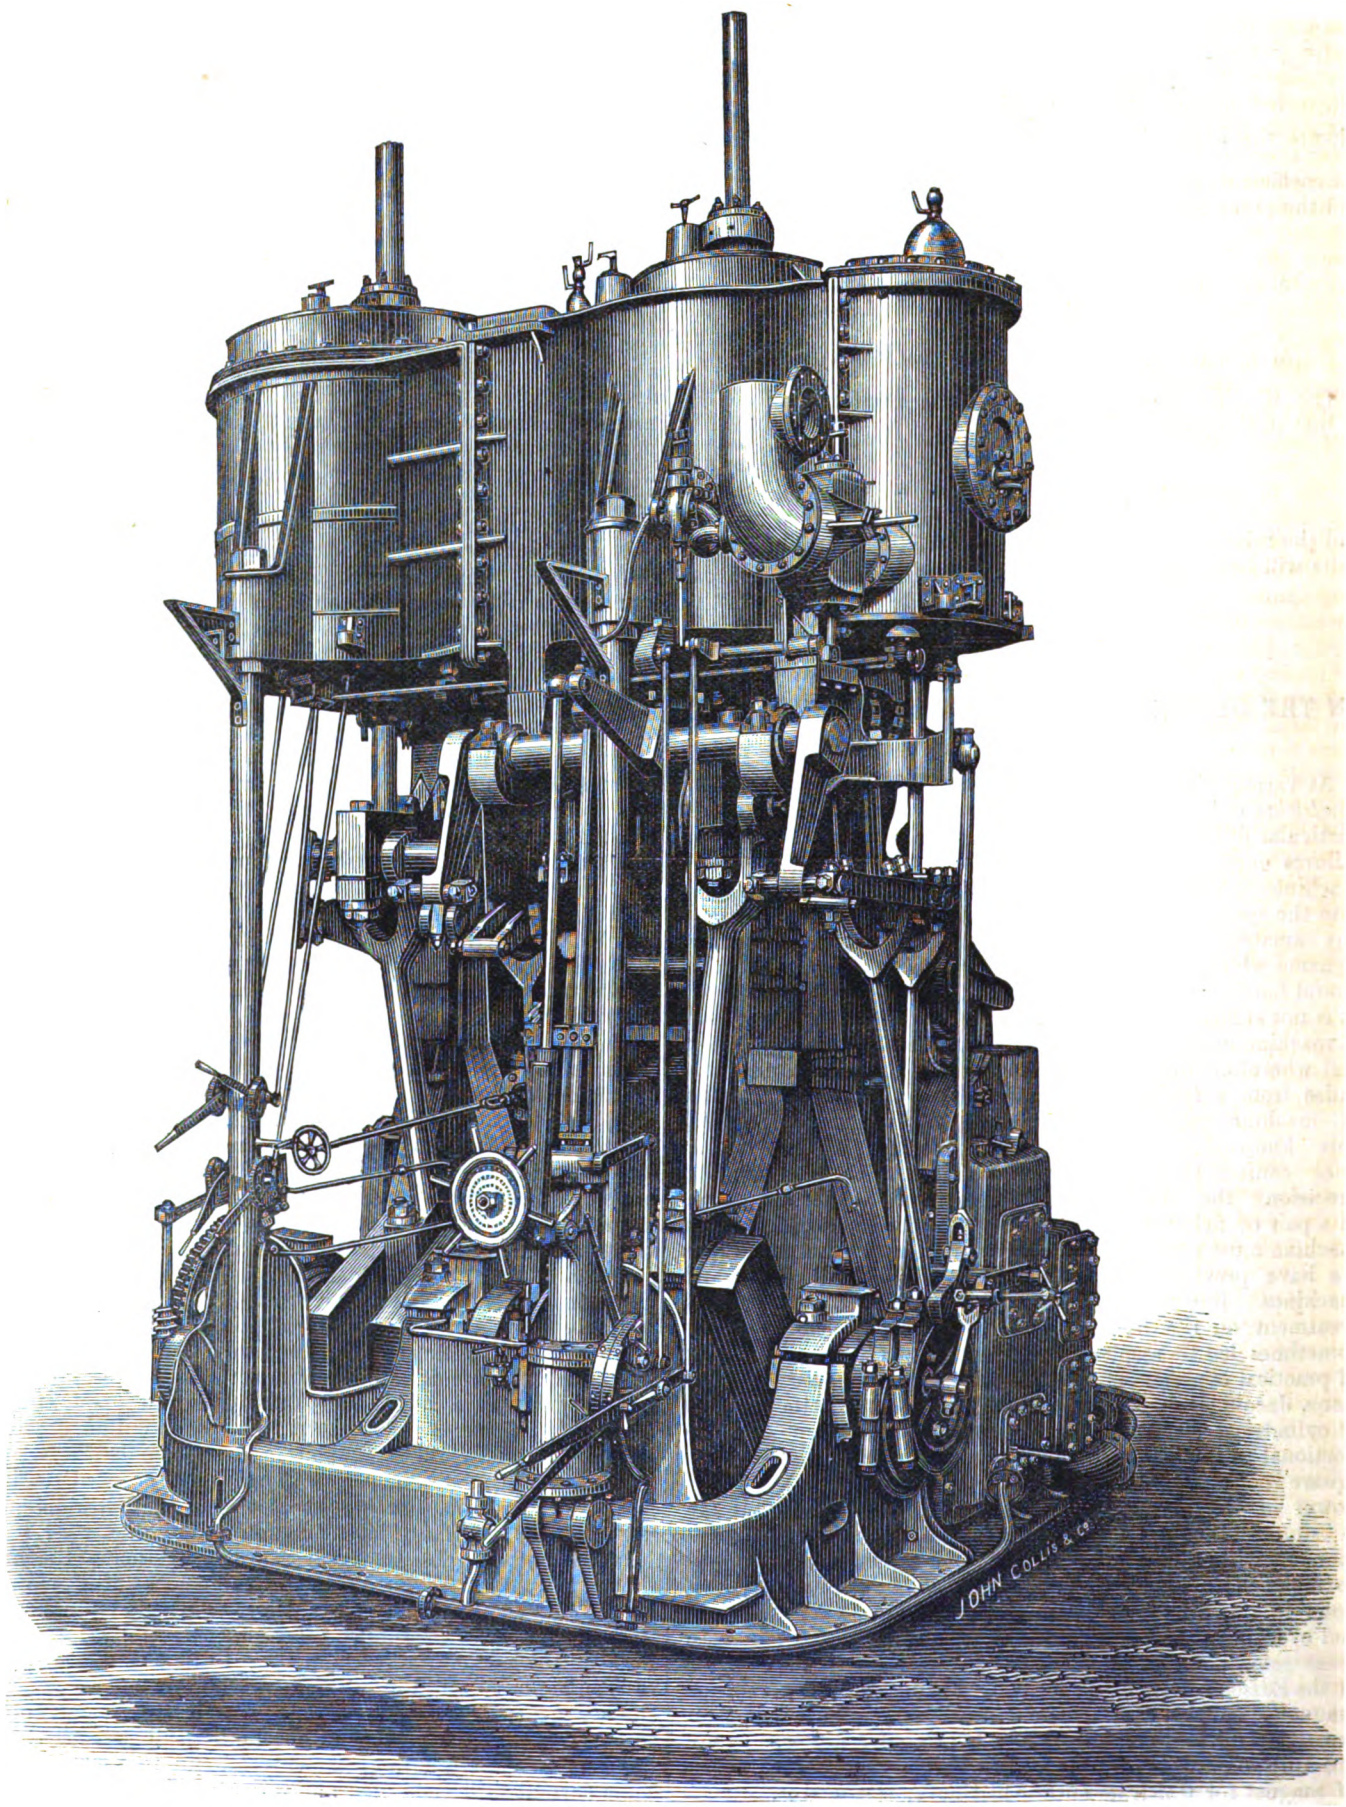
THE NEW STEAMSHIP "THE ELECTRA."



COMPOUND ENGINES OF THE ss. "ELECTRA."

Digitized by Google

THE ss. "ELECTRA."

We this week illustrate the latest addition to our cable fleet. The ss. "Electra" was built by Messrs. Napier and Sons, of Glasgow, from the designs of Mr. Joseph Birnie, of the West India Graving Docks Company, for the Eastern Telegraph Company. In speaking of the sister vessel, described and illustrated in our issue of January 3rd, we referred to these vessels as splendid examples of the forethought and enterprise of our cable companies. They have been built and fitted throughout with the view to make them perfect for the work in which they are to be engaged. We may be permitted to lift the veil of cable management for once, and to strenuously assert that it is by no means a bed of roses. The breaking down of a cable is very different to the breaking down of a five-barred gate, and we may say that breakdowns are unfortunately by no means infrequent. They are not flaunted in the face of the public, as may well be imagined; in fact, except in cases where messages cannot be transmitted, are rarely known outside the offices of the companies. Duplicating and triplicating the lines doubles or trebles the chance of faults, but, at the same time, is one of the most effective methods of preserving uninterrupted the channel of communication. It rarely happens that the two or three alternative lines are down at once. Periodically the shareholders know the cost of maintaining their lines, but they cannot realise the anxieties of their officers under the uncertain incubus of not knowing what an hour may bring forth. Elsewhere we give a list of the Eastern Company's cables and connections, and we may say that it is not unknown to have from, say, four to eight breakdowns in the system at the same time. The problem to be decided by the management is no easy one, and may be said to be—to have sufficient *materiél* in ships, men, and appliances, so that all faults may be remedied with the least possible delay, yet, while achieving this very desirable work, to minimise the expenses. Well-found repairing vessels are then a costly necessity. The better they are adapted for their work the more economical to the shareholders.

The vessel we now illustrate is intended for the Mediterranean Station. It has the following dimensions:—

	ft.	in.
Length between perpendiculars	230	0
Beam (moulded)	32	0
Depth of hold, top of floors to top of maindeck beam	16	9
Depth, top of floors to top of awning deck	24	0

Tonnage B.M. about 1,096 tons.

The ship is to run 12½ knots on trial, and 11 knots when working with a consumption of 14 tons of coal per day; she carries coal for sixteen days' steaming. The ship is built wholly of steel except keel, stern, and rudder frame, which are of iron, and is fitted with water ballast tanks, as shown in the detailed drawings. There are four cable tanks; that forward is about 25ft. by 12ft., built on top of forward water ballast tank. The top of water ballast tank is ½in.; the sides of tank are ⅜in. in one length, plated vertically with double riveted external butt strips 9in. by 7-16in., the riveting perfectly flush inside. The bottom angles on top of water ballast tank are 3½in. by 3½in. by ½in., the top angles are double, 3in. by 3in. by 7-16in., inside and outside of tank, to receive the feet of pillars from girders under deck to top of tank. The inside angles have eye-bolts about 8ft. apart for life lines. The girders under main deck on top of cable tank are four in number, and extend from the engine room bulkhead to after end of fore hatch, fastened to beams by lugs, to which girders are to be riveted. These girders are 9in. by 7-16in., with double angles 3in. by 3in. by 7-16in. top and bottom. The cable tank is pillared from these girders with three pillars with feet top and bottom, riveted to tank angles and girders. The discharge valves on bottoms are supplied by Messrs. Johnson and Phillips to three out of the four tanks. Crinolines are fitted to Nos. 1, 2, and 3 tanks. The after tanks have bottoms ½in., sides ⅜in., and strips 7-16in., with angles similar to forward tank. The eyes of Nos. 1, 2, and 3 tanks are cone-shaped, tapering from 6ft. to 3ft. at top, with portable tops, and form fresh water tanks.

The main deck is plated with steel, according to Lloyd's rules, covered with 3½in. by 6in. pitch pine deck, in long lengths. Like the sister ship, this vessel is supplied with cylindrical condensers by Messrs. Starnes and Son; but we may for a moment interpolate among drier reading, and mention that every care has been taken for the comfort and convenience of the crew. The cabins are commodious, those of the chief, second, and third officers and electricians being deck cabins, plated in ends and sides with steel, the fittings and doors being of polished teak. The engineers' cabin and bath room, and the second and third engineers' cabins and mess rooms are—except lining—wholly of polished teak, and, as we say, in all cases there has been every effort made to secure good ventilation, comfort, and convenience. The saloon is of teak and maple, with circular panels, gilded capitals, and overhead moulding; the half pillars are of fluted walnut, gilded; the overhead of saloon is in flatted white, picked with gold on edges of mouldings; the chart house is framed of pine, with teak combings, the top clyde shaped with a teak deck; the inside fittings are of teak. We do not remember to have seen anywhere—and it may therefore be interesting to give—the fittings of a cable ship's workshop. The workshop of the "Electra" for the engineers is aft, fitted up in pine, lockers painted, grained and varnished, entrance from engine room through watertight door or from main decks. It contains, besides vice, bench, and lockers, the following tools, manufactured by James Mackenzie and Co.:—One gap lathe, 7in. centres, screw cutting, self acting, with change wheels, chuck plates, counter-shafts, &c.; one vertical double-geared 1¾ spindle, with revolving and elevating table, with fast and loose pulleys; one complete set of American twist drill, a continuous line of 2in. shafting (bright), with hangers and drums; engine fitted on to bulkhead capable of driving the whole tools, with copper steam pipes from main and donkey boilers, valves, &c.; cords and bands fitted to all machines; grindstone and trough, with fast and loose pulleys and band, spanners and tools, all fitted into racks on sides of tank; a full and complete set of steel turning tools for wood and iron, with handles, two drawing boards, and two squares. The testing room is built on awning deck in line with the wheel house, wholly of teak. The inside of the room is lined with V match boarding of polished teak, the other fittings being of teak. The ship carries six boats—viz., two life-boats, 24ft.; two cutters, 18ft. and 20ft.; one gig, 25ft.; one dinghy, 12ft., all fitted with head and stern sheaves and back spars. The ventilation is by the steam system of Messrs. M'Whirter, Roberts, and Co., and may be thus briefly described:—A 10in. circular pipe is fixed on both sides of main deck, under the beams and over the scuttles, extending from officers' room 80ft. forward as far as fore-end of forecastle each side, connected with 16in. cowl heads; a 10in. circular pipe, fixed on both sides under main deck and below saloon, extending aft to engine room bulk head, also connected with a 16in. cowl head, and holes 16in. × 4in. are cut close to ship's sides through decks in all cabins, which are connected with pilasters to the same with an internal diameter of 6in. by 4in., reaching to a height of 6ft., and ending with a 6in. ordinary brass cabin door ventilator. Ventilators are also fitted on awning deck for downcast, and two 10in. pipes are fitted on both sides under forecastle, with ventilators carried to upper deck.

The cable gear is similar to that in the "Magneta," and has been manufactured by Messrs. Johnson and Phillips, being of the best and most modern design and construction, consisting of bow guards and triple sheaves, davits, crosspiece, and three tackles, stopper hooks, and plummer blocks built into the bow of the ship; dynamos for both picking up and paying out gear and lead wheels; a double-combined picking-up and paying-out machine, with engines designed especially for the ship, with holding back gear for paying out and draw off gear for picking up. To insure rigidity and avoid pillars in between decks, fore and aft foundation plates are riveted to steel main deck, with well plates, double angles top and bottom, having a foundation plate and chocks fitted overhead between deck beams in way of holding down bolts. The main

Digitized by Google

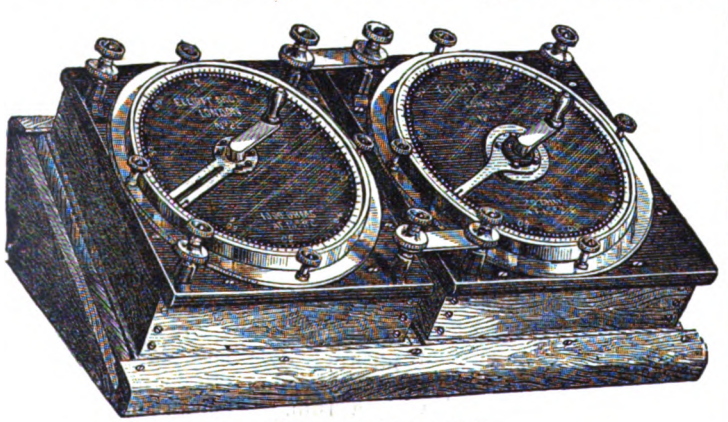
deck is carried right through between girders, and teak chocks between same. The cable gear is connected to main and donkey boiler, with copper pipes arranged not to cross the cable tanks, felted and covered with canvas and painted, with all stop valves and fittings. Of course it is to be expected that a modern vessel would be lighted by electricity, and we find that this ship is so lighted. Beside the incandescent lamps it has five arc lights and one powerful search light on bridge, with reflector. The lighting work has been carried out by Messrs. Johnson and Phillips, of Charlton.

Engines.

The engines of the "Electra," which we illustrate on p. 260, were built by Messrs. R. Napier and Sons, of Glasgow, and are similar to those of the "Magneta." They are of the compound, surface condensing, direct-acting type, fitted with all the latest improvements, and having two inverted cylinders 32in. and 64in. by 3ft. 6in. stroke. The crank, shaft, and piston rods are of steel. To facilitate the quick handling of the engines necessary in such a ship, Brown's latest improved reversing engine has been fitted, and besides the usual circulating pump there has also been fitted one of J. and H. Gwynne's centrifugal pumping engines for circulating water through the condensers and pumping from the bilges; also a special donkey, with an elaborate system of pipes for pumping from the cable and ballast tanks. Steam is supplied to the engines by two single-ended cylindrical steel boilers, with three of Fox's corrugated furnaces in each, and fitted with Galley's patent firebars. The engines are capable of developing 1,400 indicated horse-power, and of driving the ship at a speed of 12½ knots.

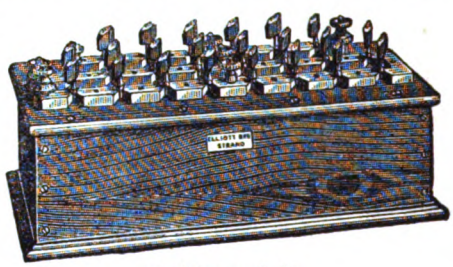
Electrical Apparatus.

The instruments for the testing room are perhaps the most complete that will be found on any vessel afloat. By the courtesy of Messrs. Elliott Brothers, of 101, St. Martin's-lane, who have supplied the electrical apparatus, we have seen many of the instruments and much of the apparatus destined for



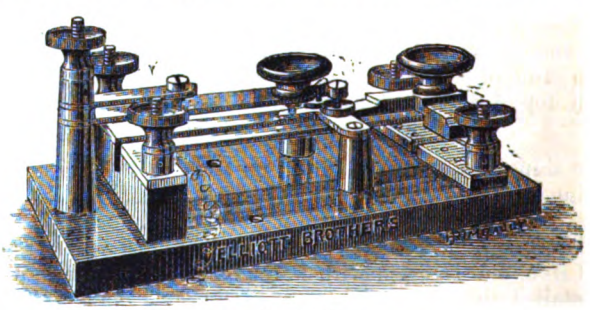
Sliding Resistance Coils.

the "Electra" before leaving the works. A brief reference to some of the chief instruments may be interesting:—*Large Marine Galvanometer.*—This instrument is an enlargement of the well-known form, the iron box being 6¼in. high and 6½in. diameter. The resistance of the bobbin is 30,000 ohms, and the constant from 40 to 50 megohms. *The Sliding Shunt* is a convenient form of shunt, with eleven multiplying powers, viz., 2, 3, 4, 5, 6, 7, 8, 9, 10, 100, 1,000, the changes being rapidly made by a sliding arm, as the name implies. *Platinum Silver Coil.*—This instrument is already well known; an extension of the bridge is, however, made, enabling readings to be taken from ·001 of an ohm to 10 megohms. *Sliding Coils.*—These coils are according to the arrangement of Sir W. Thomson, the resistances being varied by moving arms instead of plugs. They are made in pairs, one having 101 coils of 1,000 ohms each, and two contact arms embracing two coils, and the other 100 coils of 20 ohms each and one contact arm. The coils are used as the arms of the Wheatstone bridge. *Megohm.*—This resistance is divided into four sections of 250,000 ohms each, the coils being wound on about 40 bobbins, in order, as in the 250,000 coil, to equalise themselves to the temperature quickly. *250,000 ohms Coil.*—This coil is divided into six sections—viz., 10,000, 20,000, 20,000, 50,000, 50,000, and 100,000 ohms, the ends being taken to terminals mounted on ebonite pillars. The coils are wound on as many bobbins as possible, in order to get the temperature equally and quickly. *Saunders's Signalling Key* is a light working form of key introduced by Mr. Saunders, the levers of the key having spring extensions at the back for prolonging the contacts. This key was described fully and illustrated in *The Electrician*, Vol. VII, p. 309. *Subdivided Condenser.*—This has a total of one microfarad subdivided into five parts—viz., ·05, ·05, ·2, ·2, ·5. *Brass Case Galvanometer.*—This instrument is especially designed



Resistance Coils.

for use abroad and for ship service on account of its portability. It is a reflecting astatic galvanometer, with four coils of about 7,000 ohms resistance, mounted on ebonite base, with an outer cylindrical case 8in. high and 4¼in. diameter. It has a thermometer fixed to the outer case, so that the inner temperature can be readily taken. The lamp stand with the galvanometer is solid mahogany, dead blacked, with a slide for raising and lowering the scale, and a rack and pinion for a lateral motion, a convenience for bringing the zero of the scale to the spot of light. *Shunt Coils*, now used in place of the ordinary shunt, 1-9th, 1-99th, 1-999th. It has a total resistance of 10,000 ohms, subdivided in the usual manner, so that any resistance from 1 to 10,000 can be used as the shunt. *Speaking Galvanometer.*—This instrument is mounted on a solid mahogany base, the bobbin being wound in three sections, each connected



Lambert's Key.

to terminal on the base. The sensitiveness of the instrument may be increased or decreased by the use of these sections, which can be used either singly or in combination. Spare tubes with mirrors already suspended are supplied. *50 Portable Leclanchés in Box.*—A small, convenient form of Leclanché cell, each 3½in. long and 1¼in. square, packed in an oak case, the ends being taken to terminals fixed to either side of the case itself. Besides these the outfit includes *10 Leclanchés in Gutta Percha Pots.* The gutta percha pot replaces the glass jar, usually supplied for Leclanchés. It is a box 5in. high and 3¼in. square, with a hole in the top which supports and holds the porous pot. The cells are packed in teak trays, with solid india rubber blocks screwed to the sides and bottom. These blocks serve to take off blows or jars, and, in fact, act the part of buffer springs, as well as serving as additional insulation. *Speaking Marine Galvanometer.*—This instrument has been designed for speaking; it is a modification of the marine galvanometer, the iron box being replaced by a brass one which contains the bobbin, the whole being mounted on a solid brass

Digitized by Google

pillar. It has a pair of compound magnets, which completely surround the bobbin, bringing the mirror quickly to zero; it has an adjustable air chamber for the mirror, the deflections being reduced to a dead beat. The adjustment of this instrument is such that no matter how great the motion of the ship the mirror remains stationary until the currents are sent through the coil. *Lambert's Key for Capacity Test.*—This key does away with four separate keys usually used. In taking this test it is really a combination of four keys well under hand upon one base. It is both simple in design and useful in testing. There are two condensers of 20 microfarads each, subdivided into four sections of 1, 2, 2, 5, 10 microfarads in solid teak box, as usually used in cable work. *The Small Tool Chest*, specially arranged for the convenience of everyday work, contains an assortment of files of all sizes, brace with sets of centre bits from ¼in. to 1¼in., saws, screws, &c. *Large Tool Chest.*—A much extended form of the above, and contains everything that can possibly be wanted in the work of repairing both in carpentry and metal work. *The Jointer's Box* contains all the requisites for the conveniences of jointing large spirit lamp and stand, smoothing

Galvanometer.

irons, and an ingenious clip for holding the cable ends while making a joint.

The Lighting Arrangements.

The ship is lighted, as we have said, with the electric light by means of 105 20-candle Edison-Swan lamps, in addition to which there is a powerful search light fixed on the bridge. The current is generated by four Gramme dynamos, driven by two separate Willans high speed engines. Three of these machines are devoted to the incandescent lighting, and the fourth machine furnishes the current for the search light. The engines and dynamos are fixed in a space specially prepared for them, adjoining the engine room. The wiring of the ship has received special attention, and highly insulated wires have been used throughout.

The Edison-Swan bayonet sockets for the lamps have been used throughout, and these are attached to suitable brackets. Between decks, over the tanks, &c., the lamps are protected by a wirework cover, while on deck the lamps are protected with a thick glass weather-proof cover. There are six lamps fixed over each cable tank, and the gear, the bulk of which is between decks, is also well lighted by several lamps fixed at suitable points, and protected from injury by wire cages. The circuits are divided into four distinct branches, each with its complement of lamps. They are all joined to an elaborate switch board consisting of several pairs of brass bars, one set of these bars being placed above, but at right angles to those beneath, to which they can be connected by means of a screw plug. By means of this arrangement it is possible to switch any one dynamo on to any of the four circuits, or on to more than one if it is desired to work more than one circuit by one dynamo. In fact, every possible change in the connections can be very easily made. Any dynamo or circuit can also be switched on to the ammeter or the voltmeter, and in addition to these instruments, by which careful measurements may at any moment be taken, there is in the dynamo room a pilot light from each circuit as a guide to the attendant in charge of the machines, the whole arrangement having been carried out by Messrs. Johnson and Phillips.

MATHER AND PLATT'S NEW DYNAMOS.

The dynamo is a modification of the original Gramme type, carried out on the same principle as Dr. John Hopkinson's reconstruction of the Edison dynamo. The mass of iron in the magnets and core of the armature is very largely increased, and the length of the magnetic circuit is shortened. The machine has a double magnetic circuit, which though slightly diminishing the efficiency of the machine greatly increases its compactness and symmetry of form. Figs. 1, 2, and 3 show respectively a plan, front elevation, and end elevation of

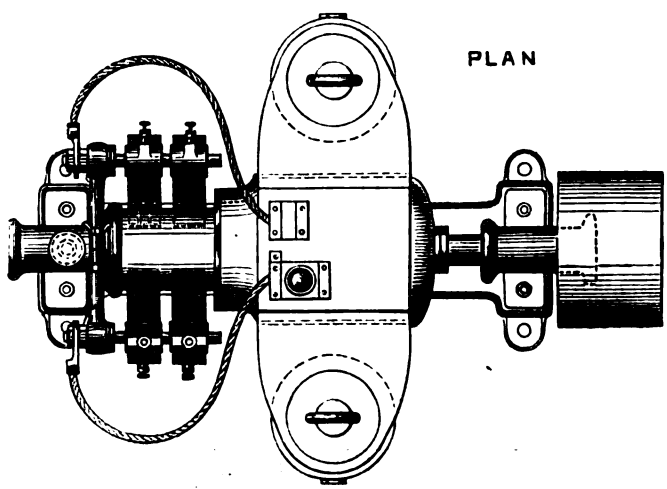


Fig. 1.

a 150 to 200 lamp machine, compound-wound, for 100 volts and 125 amperes, at 1,050 revolutions.

The shafts of the magnets are made of wrought iron, and let into cast-iron pole pieces, which have an increased section

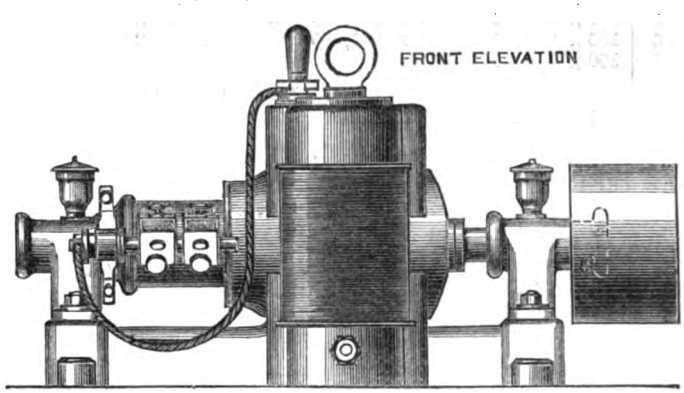

Fig. 2.

proportional to the lower magnetic permeability of cast iron over wrought iron. The lower pole piece is extended to form the bed of the machine, thus securing great compactness, keeping the centre of gravity of the moving parts as low as possible.

The armature of the machine has a free space left along the shaft to secure internal ventilation, and the commutators are large compared with the general dimensions, in order to diminish the sparking by giving as large a surface of contact

Digitized by Google

as possible between the brushes and commutator bars. The commutators of all the machines have 40 bars of toughened brass and are insulated with mica.

In the machines for 100-lamps for high outputs there is a double brush on each rocking bar, capable of separate adjustment, with a spring forward thrust and butt contact. The machines are all compound wound for constant potential at the terminals, the series coils being external to the shunt coils. These changes in the Gramme machine have very largely increased its efficiency, so that the machines of the new type are not much inferior in efficiency to the Edison-Hopkinson machine, which has probably very nearly the highest efficiency attainable.

The perfect ventilation and low resistance of the armature enable these dynamos to carry a large load in proportion to

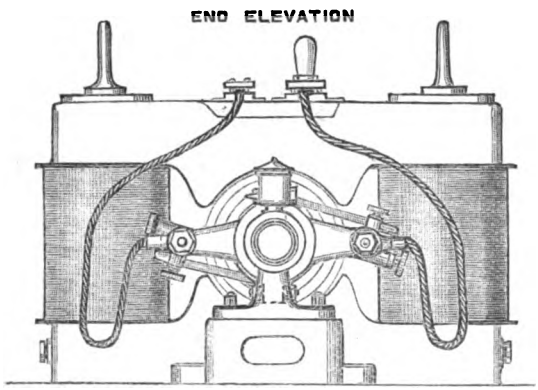

Fig. 3.

the size of the machine without heating. In fact, the load on the armature is determined by quite other considerations than that of heating.

Each machine is provided with a switch-board carried on the upper yoke, and fitted with a main plug switch and suitable terminals.

Messrs. Mather and Platt are at present manufacturing the following sizes :—

No.	No. of 20-c.p. lamps.	EMF. in volts.	Output in amps.	Speed.	Extreme dimensions. Length.	Height.	Breadth.	Size of Pulley.
					Ft. in.	Ft. in.	Ft. in.	
1	30 to 40	50	50	1,650	2 3	1 2	1 9	6×4
2	50 ,, 60	50	75	1,150	2 8	1 2	1 10	8×4½
3	100 ,, 130	100	80	1,100	3 4	1 6	2 4	10×6
4	150 ,, 200	100	120	1,050	3 6	1 7	2 6	12×8
5	300 ,, 340	100	220	850	4 3	1 10	3 2	14×9

The Telephone in Austria.—The Telephone Company of Austria has during the past year made great strides in the towns of Prague, Trieste, Gratz, Lemberg, Krakau, Czernowitz, Pilsen, Rickenberg, and Bielitz, for which the company holds exclusive concessions. In January, 1884, the number of subscribers was 436, which has now increased to 811 ; and it is expected that at least 400 additional paying subscribers will be connected up during the present year. The above will be of interest to the shareholders of the Consolidated Telephone Construction Company, as that company is a large holder of debentures and shares in the Telephone Company of Austria, and, moreover, manufactures all the instruments which are used in the Austrian exchanges.

Eastern Telegraph Company.—The *Standard's* correspondent at Rome wires that the telegraphic connection of Assab with the Suez and Aden cable of the Eastern Telegraph Company has been voted unanimously.

West Coast of America Telegraph Company.—The gross earnings of this company for the month ended January 31st amounted to £4,615.

NOTICES OF BOOKS.

A Pocket-book of Electrical Rules and Tables for the Use of Electricians and Engineers. By John Munro, C.E., and Andrew Jamieson, A.M.I.C.E. 2nd Edition, Revised. [Charles Griffin and Co., 1884.]

The march of events is too much for us, or rather we should say the intrinsic merits of this work are such that within twelve months two editions of it have been called for, and we understand a third is in preparation. We remember in years gone by in another place writing of another book which had obtained a brief popularity, that its deserts were better than its merits. The contrary is the case with the book before us in that it merits its deserts. Although the time between the issue of the first and second editions was very brief, a very large number of emendations were carried out, and we have no doubt others will be made in the forthcoming edition. Thus p. 2, "*Force* is that which produces motion, &c." This is only true in a strictly scientific sense, and when molecular motion is considered, we should prefer the ordinary definition. Again, p. 4, why is (N-seeking) pole specified ? But we venture to affirm that the value of the book lies not in its definitions ; and when the matter of practical value is considered it is excellent in quality and superabundant in quantity. There is one slight fault which might be amended, in that the authors seem to choose their authorities, naming some frequently, nay ostentatiously ; using others, but naming them infrequently ; giving contemporary publications in cases where their work is evidently nothing more than paste and scissors, and not mentioning them where the matter in question was contributed directly to their columns. The cable engineer will find this book a necessity. Never before has so much information been collected in so small a compass. He has here in handy form his formula, alternative methods, and diagrams of connections. Similarly, provision is made for the electric light engineer, the electro-metallurgist, the electro-chemist ; though perhaps not so completely. But Rome was not built in a day ; and if the second edition is better than the first, the third will be in advance of the second. And thus we go on towards perfection.

Magneto and Dynamo-Electric Machines, with Description of Electric Accumulators. From the German of Glaser de Cew. By F. Krohn, and specially edited, with many additions, by Paget Higgs, LL.D., D.Sc. [London : Symons and Co., 27, Bouverie-street, E.C. ; Edinburgh : Young Pentland, West Nicholson-street.]

It is now more than two years ago since we noticed the original of which the volume before us is a translation and extension. Almost all the best known machines are here described and illustrated, and in addition we have more or less complete accounts of Clausius's theory of the dynamo as well as the discussion of certain other theoretical questions. Although the book cannot be said to add anything to our knowledge of the subject, it seems to be a very good translation of the original work. The additions are certainly not the most unimportant part of the volume, although the theories therein given have been subjected to very severe and adverse criticism. We may say that this volume forms the first of a series which is called "The Specialists' Series."

PROFESSOR TYNDALL ON THE SOURCES OF ELECTRICITY.

In his lecture on the 1st ult., Professor Tyndall reminded his audience that in the preceding lecture he mentioned incidentally the action of atmospheric electricity, and he now, by the kindness of Sir James Paget, was enabled to show some garments which had been worn by a man who, during a thunderstorm, took refuge under a tree. This was a very dangerous proceeding. The tree was struck by lightning, as was also the man, on whose clothing it had an extraordinary effect. His clothes must, however, have been very wet when he was struck, for had they been dry he would certainly have been killed. It was the clothing and not the man's body which had conducted the electricity. Displaying a boot, the sole of which was a mass of hobnails,

Digitized by Google

and which had evidently belonged to a "son of the soil," he said they must remember that the destructive effects of electricity were produced entirely where this wonderful power encountered resistance. So with this boot, they saw a part of it where the leather had been all torn; but in the sole the conductivity was good, and where the foot was on the ground the electricity passed harmlessly to earth. Resuming his lecture proper, Professor Tyndall called attention to what he dercribed as a beautiful machine, which they owed to Mr. Wimshurst, of the Board of Trade. It would, he said, take him some time to go through the philosophy of the machine, nor was he sure that he could do so. There was considerable difference of opinion about it. In 1777 a man named Bennett invented what he called the Doubler, to augment the strength of an extremely small amount of electricity. After him came a most ingenious electrician, Cavallo, and after him Nicholson, who published a very famous journal, and who invented another way of starting from an extremely small amount of electricity, so as to enhance its value and to make it a very large amount. That was briefly and vaguely explained by the principle of Wimshurst's machine, which they then saw before him, and which was so constructed as to show them a number of pleasant experiments. In the early days of electricity there was talk of crackling and fire produced by the friction of amber and sticks of sealing wax, and the machine would enable them to hear and see the crackling and the sparks. An interesting experiment was then given to show this. They had now (he continued) to dwell a moment on that subject of supreme importance which closed their last lecture—the Leyden jar, which was first described by a canon named Kleist. It was discovered a little time afterwards by Cunæus, of Leyden, and with great justice called after him the Leyden jar. Exhibiting a Leyden jar, and placing it on a cake or bed of resin, the lecturer said he would pour as much electricity as he could (experiment) into the interior of the jar, which was coated with tinfoil. The positive electricity acted through the glass on the outer coating. It attracted the negative electricity of the outer coating, and repelled the positive; but, the jar being insulated, the positive and negative existed side by side in the thin outer coating. When he connected the inner and the outer coating, they would get no discharge. [Experiment.] First of all, he cut the outer coating from all connection with the earth, then by means of a piece of wire in his hand he established a connection and the union of the electricities, when he put the coatings into contact and produced powerful sparks. A ball was next placed by his assistant in front of the lamp, and some bran was put under the ball. The image of the ball was then cast upon the screen, when the bran was seen leaping up to the ball, the lecturer explaining that instead of allowing the electricity which he had poured into the jar to escape through the wire to the earth he had let it go to the ball in front of the lamp. The question might have occurred to some clever boy present, Why do you waste the electricity of the outer coating by allowing it to flow to the earth? Why not send it into a second jar? Producing a second jar, he gave an experiment to illustrate this. He then poured electricity into the first jar, which was communicated to the second jar, and by means of the wire he communicated the electricity to the ball in front of the lamp, when, with the aid of the screen, the bran was seen to jump up as before towards the ball. He next placed a knob at the end of the arm of the prime conductor at some distance from the jar nearest to it, explaining that the knob was charged with electricity. The electricity was thus, without any contact, passed to the first jar, then to the second jar, and communicated through the wire to the ball in front of the lamp, and the bran beneath was again seen to be excited as before. The action in this experiment was not, he explained, due to direct electricity, but to the inductive action of the electricity. The experiment was carried out on the previous day at a greater distance from contact, but they had been enabled to do that owing to the fact that the air was not so moist as it was at that present moment. The Leyden jar was, he said, capable of all kinds of modifications; and he thought that no exercises could be better for a boy than making some of these modifications. He displayed a kind of jar which, he said, he devised some time ago. He had a piece of vulcanised india rubber. Clasping Mr. Cotterell's hand, he stated that his own hand was the interior coating of the Leyden jar, Mr. Cotterell's hand being the outer coating. [Experiment.] They had there a large battery, charged with electricity equivalent to fifteen Leyden jars. All the interior coatings were united together, and all the outside were connected with the earth. Producing a thin piece of silver wire, a weight was placed at each side of it. He then spanned from the knob of the prime conductor to the weight resting on one side of the wire, and sent the discharge through. The wire was reduced to a black powder. The prime conductor, he explained, was connected with the electric battery through the wire. They had heard him carefully warn Mr. Cotterell to keep clear of the arm of the machine, and he would tell them the reason for that. When he (the lecturer) was standing in that place some years ago addressing a similar audience, with a battery charged with equal force, his shoulder was struck by the arm of the machine. The result was absolutely nothing injurious to himself, but the wonder to him was that he had not fallen. He did not believe one member of the audience knew what had occurred, though they saw that something had happened. After standing a moment or two he seemed to open his eyes, though he supposed they had been open the whole of the time, and he saw a confused mass of apparatus before him. The optic nerve was so affected that he appeared to see himself in pieces, and it was some time before the retina assumed its normal condition. He would now pass from the region of frictional electricity into another region. He exhibited a large conductor, which was placed on two stands, and brought it into contact with the prime conductor. He explained that he brought this conductor for a special reason—because it was exactly the size of the conductor devised by Lord Mahon, to whose celebrated experiments on the return shock he referred. Near the large conductor, but not in contact with it, was a second one, from which a wire passed to the lecturer's hand. When the machine before them was worked the conductor was charged with positive electricity, and it would act on the adjacent conductor, driving the positive electricity through his body into the earth. Mr. Cotterell would take a spark from the knob at the end of the conductor. At each spark Mr. Cotterell took from the machine he (the lecturer) received a shock. There was a return of electricity into his body, and that was what Lord Mahon termed the return shock. In 1786 the celebrated Galvani was making experiments with a frog. It was well known before that electricity affected the limbs of dead frogs. That was not wonderful; but what was wonderful was this. Galvani was working in his laboratory with the limbs of these dead frogs. The limbs were at some distance from the conductor, and it was observed that every time a spark was taken from the conductor a quiver occurred in them. At that time the return shock had not been explained. They were now going to an entirely different region of electricity from that which occurred in Galvani's laboratory. Galvani took a frog, hung it to a railing outside his laboratory, and watched it throughout the day. In attaching the limb of his frog he had it placed on with a copper wire, and the rail was of iron, and when the frog's limbs came into contact with the iron Galvani noticed a quivering of the limbs. Exhibiting a plate of zinc, he said that the frog they saw was suspended by a piece of copper wire. This was the second discovery of Galvani which led to the great discovery of voltaic electricity. Volta, a great man, heard of Galvani's experiment, and first of all he disbelieved it, but he worked at the subject, and became convinced that Galvani was right! The lecturer now produced a pile, which he said was similar to the first made, and was the germ from which the electric light had grown. They had before them the voltaic pile, and they could see that the manner in which it was put together justified the term "pile." In the year 1800, in which Volta discovered or described the pile, Nicholson and Carlisle observed by accident that when the two ends of a wire from a voltaic pile were immersed in water bubbles were caused, and that one part consisted of oxygen and the other of hydrogen. [Experiment.] The wire was immersed in a small cell containing acidulated water, and the lecturer sent a current of electricity to either of these wires, and they saw on the screen that bubbles rose from the water. One voltaic cell was insufficient to overcome the attractive force, but the two should overcome the attraction. He had spoken of the atoms of oxygen and the atoms of hydrogen. They united so as to form a molecule. He had there a solution of a compound of lead —acetate of lead; and by sending a current through this solution they would decompose the solution, and on one of the wires would be the deposited lead. The minute particles of lead had the power of crystallising, and he showed by an experiment, with the aid of the screen, that they did not scatter themselves in a confused manner, but presented themselves in beautiful fern-like forms. Subsequently he gave illustrations of electro-plating, some copper plates being made to present the appearance of silver after the experiments. He next called attention to a great discovery by Sir Humphrey Davy with soda and potash, who produced a metal potassium. The affinity for potassium from oxygen was shown.

Danger of Constant Batteries.—Precautions should be taken with batteries in which polarisation is prevented by surrounding the electrode with nitric acid, giving rise to a reduction of the acid and a disengagement of nitrous vapours. Several cases of poisoning from such vapours are on record, notably at the hospitals of Bonn and Halle. A chemist who had worked for some considerable time in the fumes of nitric acid gradually became poisoned, and his recovery was slow, while a girl actually died twelve hours after carrying a vessel of nitric acid through the streets.

TELEGRAPHS TO THE EAST.

Last week we had to comment upon the history and prospects of an electrical industry whose short career has been full of vicissitudes, and whose future prosperity is still a matter of uncertainty. To-day our attention is directed to another class of electrical enterprise whose success has never been doubtful from the first, whose growth, if it has been gradual, has never been interrupted, and whose future is as sure as any human undertaking can be said to be. About the success of electric lighting companies various untoward circumstances keep us still in doubt; if there ever was a doubt about the success of submarine telegraphy it is so long ago that we have forgotten it; and the report of a recent meeting of one of the largest submarine telegraph corporations, which we print in another column, shows that, by a wise combination of foresight and boldness, backed by good management, telegraph cables, although among the most fragile, are one of the most valuable of properties, and the business of working them one of the most lucrative.

In the face of disasters which have lately befallen some of the Atlantic cables our estimate may seem overcharged. But, in reality, they rather support our view. Without drawing invidious comparisons, which, indeed, we have no right to do, as the fault does not rest on the English side of the Atlantic, it must be apparent to all that the suicidal competition into which the several companies working between here and the United States have launched does not fulfil the conditions of success referred to above. Turning back at random to *The Electrician* of October, 1878, and looking at the market price of telegraph shares there quoted, and then comparing them with those given of the same month last year, we find that, with some insignificant exceptions, the companies working to the East, of which the EASTERN TELEGRAPH COMPANY seems to be the foremost, have nearly doubled, and in some instances more than doubled, the value of their shares. The same lists relating to the cables to the West show exactly opposite results, the depreciation being 50 per cent. or more. The bottom of the Atlantic indeed has been made the arena of financial speculation and reckless competition; no sooner has one cable been successful than another has been laid by a competitor; and, what is still worse, the laying of every fresh cable seems to be the signal for the others to mysteriously break down. Through no fault of their own the English companies to whom we owe our telegraphic communication with America have had to bear the brunt of a rivalry which conduces nothing to the public welfare, and has very much the appearance of being vindictive.

Happily from these forms of disaster the Eastern telegraphs have been almost entirely free; and what little of haphazard or speculative cable laying has occurred within the area covered by them has been wisely surrendered or absorbed so as to form duplicates of the larger systems, or alternative routes for cases of emergency. A large reserve fund has contributed to these results no doubt; but a bold and forward policy has done still more. Keeping touch of the commercial and political movements of the times, the companies have not only opened up new channels for trading communities, but have made themselves the indispensable ministers of imperial governments. The consequence is that the companies enjoy a practical monopoly which is financially remunerative to themselves and highly beneficial to Commerce and to States. Without it the mileage of cables might have been as great or greater; but the cohesion, the unity, and the organisation would have been wanting. Working from different points, and independently of each other, every breakdown would cause a stoppage of communication not only between those points but with them; connect them by friendly links and the whole forms one complete system which, as Mr. PENDER stated at the half-yearly meeting of the EASTERN COMPANY last week, enabled them to dispose of a good deal of extra traffic without any delay, although several of their cables had almost simultaneously gone amiss. In the long run, this, by whatever name we may call it, is the only way in which the telegraph systems of the world can be satisfactorily worked. We are profoundly sceptical as to the outcry against monopoly in Atlantic cables. Their multiplication beyond the requirements of traffic means ruin or amalgamation; and inordinate amalgamation means inordinately watered capital.

The varied and extensive character of the systems controlled by the EASTERN TELEGRAPH COMPANY, and the companies in working agreement with it, is shown in the very remarkable table which we are also able to publish this week. If we are not greatly mistaken, the facts here disclosed will be a surprise to most people. It seems almost incredible that in the short space of time during which these companies have existed they could have spread and extended their operations so widely and to such remote

Digitized by Google

quarters of the Eastern Hemisphere. The EASTERN TELEGRAPH COMPANY and the EASTERN EXTENSION COMPANY, together with the SOUTH AFRICAN and the BLACK SEA Companies, own between them nearly 36,000 miles of submarine cables, besides 3,402 miles of land lines. To keep this vast system in working order requires constant and unremitting attention, and involves, of course, considerable expenditure on the maintenance of repairing ships. Even the British Government, with its very limited mileage of cables, have found it to their advantage to possess a suitably-equipped cable ship of their own; and, of course, these companies have long had theirs. We give this week a series of illustrations of the last new ship of this kind, built for the EASTERN TELEGRAPH COMPANY, and named the "Electra." It is probably the most admirably and completely-equipped vessel of her class ever yet built.

We cannot dismiss this subject without a word of regret that the submarine telegraphs of the world, which were projected and are owned almost exclusively by this country, are so indifferently protected by its Government. The initiative in this matter, as in so many others, has been taken by France; and the Conference relating thereto was actually held in Paris. Our command over submarine telegraphy ought to entitle us to speak with authority where its safety is concerned, and our interests dictate that we should be the first to be heard. We are sorry to say that this apparently is not the view of the Foreign Office, or the Colonial Office, or both combined; and the result is that, although some regulations have been framed that may prove of service, they are still very far short of what might be obtained if the British Government took any trouble in the matter.

CORRESPONDENCE.

PERSONAL SAFETY AND ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Sprague's letter is a treatise on the laws of electricity. As I had not seen his Second Edition, p. 299, so he has not read my papers, which date from before the Southport Meeting of the B.A. He will there find the "pans of salt-water" fully described. In his postscript, moreover, he does justice to my incomplete device, which I did not claim as new, except for this purpose. My intellectual status as a physicist is, perhaps, a shade higher in the zoological scale than he, or certainly Mr. Sydney Walker, at first intimated. I entirely acquit the latter gentleman of intentional discourtesy, though his former letter shewed a rather "hoity toity" tone from which his second is free. Here, for sheer weariness, I must leave controversy.

Two points, however, are of extrinsic value:—

1. I cannot accept Mr. Sprague's "sweeping" phrase that Kohlrausch's method of measurement is a "delusion;" nor has he given any proof that the body takes "a succession of reverse charges" like a condenser. Indeed, a thing which possesses only a few thousand ohms resistance cannot be called a condenser at all, except by wrong use of words. It is more like a faulty submarine cable, as Mr. Latimer Clark judiciously suggests; and the excellent method of Mr. Mance, to which Mr. Clark has drawn my attention, brought before the Society of Telegraph Engineers on May 8th, 1884, will probably prove of service. It is intended for "eliminating the effects of polarisation and earth currents from fault tests." In some suggestive remarks made on the paper in subsequent discussion, Mr. Clark describes experiments with artificial faults in cables thrown overboard. "The resistance of the fault," he says, "was taken with potentials varying from three to sixty cells, and it was found that in all cases, as the battery power increased, the resistance of the fault decreased with great steadiness." This also answers a question of Mr. Walker's. I may add that I *do* consider the human body an exception to the rules governing ordinary conductors, and hence arise mysterious and hitherto unexplained accidents.

I may name, in conclusion, that Mr. Glazebrook's paper published in the *Phil. Mag.* for August, on estimating the capacity of a condenser by means of a tuning fork, is under trial, and that by the kind help of Messrs. Latimer Clark, Muirhead, and Co. I hope to have the opportunity of endeavouring to balance the body against a small portion of one of Dr. Muirhead's duplexing condensers, which, like it, combine resistance, or rather conductivity, with capacity.—Yours, &c.,

Wandsworth, Feb. 2, 1885. W. H. STONE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As a discussion is now taking place in your columns upon "Personal Safety and Electric Currents," it appears to me an appropriate time to point out that I have recently suggested to the President of the Society of Telegraph Engineers it might be advisable that a committee be formed by, say, the Institution of Civil Engineers and the Society of Telegraph Engineers, for the purpose of inquiring into and reporting upon the subject.

As I feel, and I think most electrical engineers will acquiesce in my view, that the progress of electric lighting has been seriously retarded by the publication in the press of the accidents which have occurred, giving the general public the impression that *all* electric lighting currents are dangerous, I consider that good results would accrue from the publication of a report drawn up by competent men, and I suggested that such committee should consist of both electrical engineers and medical men.

Mr. Spagnoletti suggests that, as a preliminary step, a paper upon the subject should be read at the Society of Telegraph Engineers, and suggests my doing this.

I was not desirous of carrying out his suggestion, as I feel that there are several others far more competent to handle the subject than myself, but I have had the good fortune to secure the valuable co-operation of Dr. W. H. Stone.

I feel that if the paper merely consisted of a record of the accidents which have taken place, with a few observations upon them, it still might be productive of an interesting discussion in which medical men might take part; and with this in view I will ask you to publish this letter, in the hope that some of your readers will be able to furnish me with details of accidents, either fatal or non-fatal, which have occurred.

A form is being circulated amongst all those likely to be able to furnish particulars. I have already to thank Sir Wm. Thomson, Mr. Latimer Clark, Dr. Hopkinson, Dr. Richardson, Mr. Crompton, and others, for their kindness in furnishing lengthy replies.

I shall feel very much obliged to any of your readers who will do the same.

I am sorry to see that Mr. S. F. Walker speaks in such a dissatisfied tone as to what has been and is being done, and should like to point out that, although his letter is very lengthy, and contains a great number of suggestions, yet it does not add at all to our knowledge of the subject.

I cannot agree with him that the measurements Dr. Stone has made represent so much time wasted. It appears to me to be of vital importance to know the resistance of the human body under all conditions; and I would suggest that if Dr. Stone's clinical clerk does not feel inclined to submit to an exhaustive series of tests as to how much current he could stand in different parts of his body, &c., that Mr. Walker should do so himself.

Again, I am not with him when he says that very little can be done before the human body can be mapped out into circuits, &c., aad I certainly cannot see at first glance the meaning of the expression "that this vein being a conductor in motion sets up an E.M.F. within itself."

Are we to glean that the vein moves about to different parts of the body, cutting lines of force, and thereby acting as a dynamo machine?

Digitized by Google

Most of the questions he asks would, I think, be answered by the results of *post mortem* examinations on those killed by electricity.

Another point appears strange. He says, "After the beautiful models and diagrams of the human body which I have seen, and which are public property, I will not believe it to be impossible."

What have the models to do with it?

Will any valuable result accrue from taking one of these models to pieces, and measuring its various resistances?

In another part he says, "We know that an electric current has the property when passing through a nerve of exciting that nerve to perform its natural function."

This is not strictly true, a current flowing steadily through a nerve or muscle produces no effect; it is only at the commencement, or cessation of the current, that such effect is produced.

In the case of continuous currents the muscle returns nearly to its normal position, and remains there so long as the even flow of the current continues. It might be advisable to point out that it appears not to be absolutely necessary, as Mr. Walker states, that the contraction of muscles should be preceded by a violent excitation of all the nerves which lay in its path, as the passage of an electric current has the effect of contracting a muscle from which the nerves have been removed.

In the next paragraph he is also in error in stating that in the case of the alternating current we should have excitation and contraction, followed by a momentary return to the normal state. Every muscle, of course, has its own moment of inertia, and above a certain speed of alternation in the current it cannot respond, and remains contracted; hence a man will grip the electrodes, whether the currents be continuous or alternating.

I fear that I have already trespassed too far on Dr. Stone's portion of the subject, but I should like to point out that thrombosis is produced by combination of haemoglobin contained in the corpuscles with certain constituents of the liquid serum of the blood; consequently, if Mr. Sprague's suggestion that certain structures are broken down by the shock or repeated shocks be correct, this would account for thrombosis.

I think Dr. Stone's experience with a Ruhmkorff coil, in which a spark leapt three or four inches in order that the current might enter in a little unhealed wound, is of great importance, and I had already pointed out to Dr. Richardson, F.R.S., that possibly it may be found that the skin resistance is so much in excess of the resistance of the moist tissues, that animals may be killed by currents the E.M.F. of which may be sufficiently low as to be harmless to the operators by the simple expedient of allowing the current to pass through the head of the animal between two sharp points which have been allowed to penetrate the skin, and this, I should imagine, without subjecting the animal to any material degree of pain.

There are a number of other points I should like to mention, but I fear I have already taken up two much of your valuable space.—Yours, &c., ALFRED R. SENNETT.

EFFICIENCY OF INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In *The Electrician* of 17th January I find a report by the jurors of the Vienna Exhibition on an incandescent lamp exhibited there. The particular lamps tested were 20 candle-power *nominal*, and the figures given show that when run to give this light the efficiency, or number of watts per candle, was 2½; and when giving 12 and 9 candles the efficiency of the same lamp was 3·13 and 3·77 watts per candle respectively. "Of course," continues the report, "when under-run in this way the length of life should be very considerable." No doubt it ought, or at least, at first sight, one would jump to that conclusion; but let us examine some of the terms employed in the above statement. "Under-run" has no absolute meaning, and can only be understood when referred to the term "20-candle." This, again, is a meaningless expression, and conveys no information unless accompanied by the reasons why the rate of work was fixed such that the lamp would give 20 candles. Were I to take a lamp, which, on economic considerations, ought to be run at 10 candles, christen it a 20-candle lamp, and then run it at 12 candles, I should be scarcely in a fair way of making its life *very considerable*. The process reminds one of the man who on finding his feet exposed during the night tried to lengthen his blanket by cutting a piece off the top and adding it on to the bottom.

It will of course be unnecessary for me to point out that knowing only the efficiency or watts per candle of a lamp is useless information. In a preliminary experiment lately made by me on a certain lamp I found that the watts per candle varied approximately as the inverse square of the watts absorbed. The equation to the curve found by taking a great many points is $(x + n)^2 = m\ y^{-1}$, where x is the watts absorbed and y the watts per candle. Now as n is small compared with x, and m is a constant, it will be seen that y, the number of watts per candle, approximately varies as the inverse square of the watts absorbed. This relation was found to exist between very wide limits, namely, from four to twenty-six candles. It will thus be seen that to give any information as to the relative merits of different lamps it is necessary to give a curve showing the average life of the lamp when run at various efficiencies. About as much information as to the merits of a lamp can be got from its so-called efficiency as idea of size of a body can be got from knowing that it is as big as a piece of chalk.

Sir William Thomson, in a paper communicated to the British Association at the York meeting, 1881, and Mr. Thomas Gray, in the *Philosophical Magazine* for September, 1883, have calculated the size of conductor required for the distribution of electric energy, in order that the sum of the annual cost for interest on capital, for depreciation, and for energy lost in consequence of heat generated in the conductor by the current may be a minimum. Now, a similar calculation may be made to find the efficiency at which a particular class of lamp ought to be run, so that for a given total light the sum of the annual cost for interest on the price of lamps in use, for renewing lamps, and for supplying electric energy may be a minimum. Without this a comparison of the so-called efficiency of different lamps is valueless and misleading.—Yours, &c., J. GORDON.

27th January, 1885.

THE DAVEY MOTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The letter of your correspondent, "Phœnix," in last week's issue has probably perplexed more young engineers than myself. He states therein that Mr. Davey's motor house, 9ft. by 6ft., is "not too big, but just big enough." I fail to understand why these dimensions should be considered just right by one who has evidently no idea of the size of the machinery within, as he goes on to inquire what the motor is.

Considering that Mr. Davey's domestic motor has been illustrated in nearly all the engineering papers during the last few months, and is described as being eminently suitable for driving dynamos, one would have thought that even so cautious a a person as "Phœnix" appears to be might have ventured to assume that this was the motor used.

He asks, "Why burn coke?" I ask, Why not? It is a very cheap fuel, and the absence of smoke in the products of combustion, thereby preventing flues, &c., being choked up, is probably the reason why it is so generally adopted for hot air engines, small stoves, &c.

As to the remarks of "Phœnix" on Mr. Davey's system of warming his house by means of the heat obtained from the motor, I confess they are beyond me. Nothing seems to satisfy him, material, thickness, diameter of pipe, or method of carrying it through the house. One is reminded of the famous leg of mutton which Dr. Johnson condemned as being "ill-fed, ill-killed, ill-kept, and ill-dressed."

Mr. Davey states that he adopts ¼ lead pipe, which I take it signifies piping ¼in. in diameter, and I do not gather from his letter that the pipe is used to convey water; but from the descriptions one has read, it appears that steam at or slightly below atmospheric pressure is used in the motor. Perhaps Mr. Davey uses this steam; if so, why should not the pipe be

Digitized by Google

thin, the pressure being practically *nil?* As to the material, my experience in the workshop has shown me that lead pipe is far easier twisted about than iron.

Of course if "Phœnix" prefers to use iron pipes of 1¼in. diameter and to go to the expense of making recesses in his walls, he is welcome to do so; but, according to Mr. Davey, cheaper pipe can be used and carried anywhere about the house where required, and fixed with very little trouble and expense, giving satisfactory results.

As a young engineer anxious to learn, I venture to inquire of "Phœnix," in his own phraseology, If this can be done, why not?—Yours, &c.,

A YOUNG ENGINEER.

DYNAMO CONSTRUCTION.—A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I regret to see several rather serious misprints in my letter in your issue of this date.

The second equation

$$E_{,} = K\,\omega\,\frac{W}{a}\,V \quad \textit{should read}$$

$$E_{,} = K\,\omega\,\frac{W}{a_{,}}\,V.$$

The dash is also omitted farther on in "W lbs of wire, *d* mils in diameter," which *should read d,* mils in diameter.

Again, in giving a formula for the number of turns of wire around the magnet coils, "$V = \frac{\omega}{C_{,}}$" *should read* $\gamma = \frac{\omega}{C_{,}}$, and farther on, where the value for $C_{,}$ is substituted, "$V = \frac{\omega E_{,}}{E C}$" *should read* $\gamma = \frac{\omega E_{,}}{E C}$.

But the "hardest cut of all" is where the words "*my* comprehensive formulæ" appear instead of *any* comprehensive formulæ. No doubt it is nearly impossible to avoid such errors entirely where it is impracticable to allow correspondents to revise their proofs, especially if the correspondents happen to be bad writers, as I fear is my case.—Yours, &c.,

G. C. FRICKER.

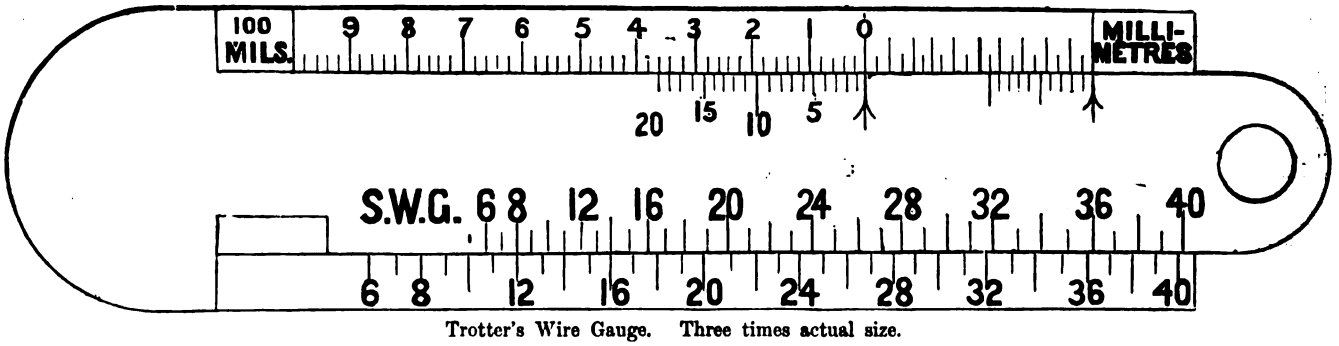
7, Charlwood-road, Putney, Jan. 31, 1885.

LIGHTING YACHTS BY ELECTRICITY.

The new yacht "Retreiver," belonging to Mr. O. Randall, has just been fitted throughout with the electric light by Mr. Geere Howard, of 36, Cleveland-street. The saloons, cabins, and engine room are lighted by incandescent lamps of 20 candle-power each, distributed as follows:—Six in the saloon, three in the chart room, one in each of the cabins and passages. The engine room and passages are fitted with portable lamps, so that any part of the vessel can be lighted at will. For this yacht, having a magazine, as it carries five guns, a special arrangement has been designed for lowering an incandescent lamp down into the magazine, doing away with any possibility of fire or explosion through accidental ignition of the powder. Besides the incandescent lighting an arc lamp of 3,000 candle-power, fitted with all the most recent improvements, is arranged for use as a search light. This search light is fitted with a powerful projector and lens. Both the search light and the incandescent lights are arranged in parallel arc, the current being supplied by one of the Crompton compound type of dynamos, driven direct by a Tower spherical engine. The engine and dynamo are fixed upon the same bed plate, and only occupies a space of 4ft. by 2ft. 7in. by 18in. The lighting of the vessel is not the only use made of electricity on board, for an arrangement is being made by which the guns can also be fired by electricity from the chart room, and the arrangement will be such that either or all of them may be fired simultaneously or independently as required. The whole of the installation is of a special character, on account of the small available space, the whole of the designs having been made and the work carried out under the superintendence of Mr. Howard. It seems to us that the owners of yachts will do well to follow the example of Mr. Randall, for as these vessels are mostly built for pleasure purposes, and the electric light being calculated to be superior in every respect to any other kind of ship lighting, it should become the rule without an exception.

[A number of letters, although in type, are unavoidably crowded out. Amongst these are communications from R. H. M. Bosanquet, Douglas C. Bate, and W. A. Rudge.]

TROTTER'S GAUGE.



Trotter's Wire Gauge. Three times actual size.

Following on the publication of their admirable "Table showing the Relative Dimensions, Lengths, Resistances, and Weights of Pure Copper Wire," now so well known in the electrical world, Messrs. Walter T. Glover and Co., of Manchester, have brought out and patented a new wire gauge, the inventor of which is Mr. A. P. Trotter. This gauge will be found to be one of the handiest invented, as it gives five measurements at one operation, each of which is registered with great accuracy. The largest scale on the gauge is that of the new Board of Trade Wire Gauge, styled the S. W. G., or Standard Wire Gauge. This is marked from No. 6 to No. 40, every size between these two numbers being distinctly shown at once without the necessity of first counting the number of mils the wire may measure, and then referring to a table to see what particular number of the S. W. G. is being measured, as is at present the case with most gauges now in use.

There is also a scale of "mils," or thousandths of an inch, and a millimetre scale, both of which, in addition to the S. W. G., are on the front of the gauge. In this way not only can the S. W. G. number be seen at once, but the diameter in mils. and millimetres can be read accurately (not approximately) without further measuring.

On the back of the gauge is another scale, showing the area in thousandths of a square inch of any wire the gauge may be measuring, and this scale also serves as a scale of amperes (calculating on the safe basis of 1,000 amperes to the square inch), so that on the scale of areas may be seen at a glance the *safe* current for any wire. Again, from this scale of areas may also be calculated (approximately) the *length*, *weight*, resistance, loss of horse-power, &c.

Indeed, the value of the gauge is such that we feel assured that electricians generally will not be slow to recognise the ingeniousness and skill of the inventor in providing so useful and practical an instrument for facilitating rapid and accurate calculations.

As we have said five measurements are made at one operation, viz., size in 'mils' and millimetres, area in square inches, and current in

Digitized by Google

amperes; while the length, weight, resistance, loss of horse-power, and also Sir William Thomson's very safe rule of 0·5 ampere to the square millimetre, can all be readily calculated from it.

The working of the gauge will be easily comprehended by an examination of our illustration. The three scales on the front of the gauge are verniers, and show the correct reading in S.W.G. (standard wire gauge) "mils" and millimetres of any wire or other article nipped between the jaws of the gauge. The gauge works like a slide rule, and all the readings, as we have already explained, are given with once measuring, the scales being so arranged that all their numbers register correctly without re-gauging.

COMPANIES' MEETINGS.

The Direct United States Cable Company (Limited).

The fifteenth ordinary general meeting of this Company was held at the City Terminus Hotel, Cannon-street, on Thursday last, Mr. John Pender, M.P., presiding.

The SECRETARY (Mr. J. W. Fuller) read the notice convening the meeting. The report and statement of accounts were taken as read.

The CHAIRMAN then said: Before moving the resolution for the adoption of the report and accounts, I shall, as usual, give you a few figures relating to the report, and make a few remarks which I have no doubt will be interesting to you. The revenue for the half year to 31st December last, after deducting out payments, amounted to £68,824 5s. 2d., and the working expenses and other payments to £18,607 15s., leaving a balance of £50,216 10s. 2d. as the net profit of the half year, making, with £2,786 8s. 7d. brought from the previous half year, a total of £53,002 18s. 9d., which has been appropriated as follows:—Interim dividend of 5s. per share, to 30th September, £15,177 10s.; interim dividend of 5s. per share, to 31st December, £15,177 10s.; amount set aside to reserve fund, £5,396 15s. 10d.; balance carried forward, £17,251 2s. 11d. The revenue shows a decrease of about £4,650, as compared with the corresponding period of 1883, owing to the continued depression in trade with America, which has affected our earnings during the last three or four years. The working expenses in London are higher, but the expenses at stations continue to show a reduction as compared with 1883. The expenditure in the past half year has been affected by the alteration of tariff, involving extra work, and outlay in printing and stationery; by the cost of advertising repayment of debenture loan, and by other causes more or less of a temporary nature. Taken on the whole, however, the working expenses and other payments are less by £3,200 than in the corresponding six months of 1883. The reserve fund has been charged with £73,367 14s. 7d., which, with the addition of our floating capital, has been applied in paying off our debenture loan of £100,000, at the same time reducing our expenditure on capital account, as shown in the balance-sheet. The balance of the reserve fund, fully invested, now stands at £300,000. We have realised £50,000 worth of Consols, in connection with repayment of the debenture loan, leaving our investments standing at a cost of £304,221 4s. 1d., which is considerably less than their present market value. These figures, gentlemen, will impress upon you the exact financial position of the Company. Now it is my duty to put before you to-day a plain and straightforward statement. I wish the Directors and the shareholders at a time like this to have a thorough understanding one with the other. When I had the pleasure of addressing you at the last half-yearly meeting I referred very fully to the position of the Company, and also to the then impending competition. I stated that Messrs. Bennett and Mackay had laid one cable, and that they were about to lay another; that when the two cables were completed we should then be face to face with an active competition. There was an idea at one time that the Bennett-Mackay cables would open at the same tariff that we were then working at—viz., 2s. per word; had they done so it would have been better for them not only at the present time but also in the future. They had, however, made so many promises to the public, and having stated that their principal object was to give a cheaper telegraphic service, and to break down what they considered to be a monopoly, that I presume they felt bound to open with a lower tariff. But did this action arise purely from a desire to benefit the telegraphing public, or from a desire to enrich themselves out of what they conceived to be a very profitable business? Or was there not a little spice of jealousy in their action against certain parties on the other side of the Atlantic, who had taken a very prominent part in telegraph communication, not only there but in connection with the submarine system? Their motives they best know themselves. However, I had more than one conversation with Mr. Bennett, and at one time thought he would take my advice, and I had also a considerable amount of discussion on the subject with the late Mr. Garrett, who I may say in passing was a very shrewd, far-seeing, and intelligent man, and whose loss is a very serious one to the commercial community of America, as there were few men there who exercised a sounder judgment, and who were more successful in developing and placing in the highest possible position the leading railways in America as the one over which he presided. I was satisfied that additional cables in the Atlantic at that particular time meant simply a waste of money, the existing cables being equal to carrying two or three times the amount of traffic offered; and most of them being duplexed, it placed the cable companies in a position far ahead of the natural growth of traffic. I therefore, after a discussion with Mr. Garrett, prepared a statement, which I handed to him. I also sent a copy of it to Mr. Bennett, and I gave instructions that a copy should be handed to Mr. Mackay. Whether it ever reached Mr. Mackay's hands, of course I cannot say. I am told it did. However, I believe that the facts given in that document decided Mr. Garrett in withdrawing from the cable combination. It is just possible that Messrs. Mackay and Bennett may have imputed my sending this document to them to other motives than those which influenced me. My desire, however, was to prevent them from getting into a business which I knew would do no good to them, but might do serious injury to the large body of Atlantic telegraph shareholders. I hope they will now see that the figures gave a very fair and straightforward statement. I showed in that document that there was a certain amount of money earned in the Atlantic at a certain rate, and I gave them figures, based upon our extended experience, which showed that if the two proposed cables secured their numerical, or cable-for-cable proportion of the total Atlantic traffic, viz., one-fifth, it would, nevertheless result in a loss of £40,000 per annum after they had provided for working expenses and a proper reserve fund, but without taking into account a very large annual expenditure for a repairing steamer. My facts, however, did not prevent them going on with the venture, and they are now gathering their experience from the working of their own cables, and I shall show you presently what I believe the result of that experience will be. Firstly, I would say that their first act of opening with a tariff of 1s. 8d. per word, and thus forcing a reduction from 2s. per word, was literally throwing away £150,000 per annum; because, so far as we can see up to the present moment, also from previous experience, the reduction will not generate any increase of messages sufficient to recoup us for that loss. And I doubt very much, if we were to take this sum and scatter it over the traffic which has passed, whether we should find that it had been of any material benefit to those engaged in telegraphing. But, gentlemen, it has been—or, rather, I may say, it will be—a most serious loss to the companies, the pioneers who have done so much to promote and maintain an efficient submarine service in the Atlantic; and if continued it will make a material difference in the dividends which we shall be able to pay to you in the future, extremely moderate as they have been in the past. Although I am addressing plain facts to you—and I am putting the case clearly and distinctly before you—I do not wish to do it in any way to deprive you of hope for the future, because I think we have it now pretty much in our own hands to make the future very hopeful indeed for submarine telegraphy; but before we get to the hopeful position, I expect we must go through a little tribulation.

Now we have to consider in what way can best protect the interests of our shareholders at the present time. Messrs. Mackay and Bennett are, of course, gaining experience; but probably before many months have passed, when they come to make their balance, they will find out that the venture they have gone into is one which, from our point of view and from the mode in which accounts are generally kept, must show them a most unsatisfactory balance. As shrewd Americans, they have been accustomed to high rates of interest upon their investments, and no doubt their money was invested in America, probably in undertakings which, judging from what one sees and hears, yielded them a return of from 6 to 8 per cent., probably more than that. They have had to realise some of these investments, no doubt, to start this new venture. They will have an opportunity of seeing this statement, and I hope they will not think I am interfering in their affairs if I put before you what I think will be the result of the working of their new investment compared with the old. I think I can show you something of what their first balance-sheet is likely to be. Take their capital at £1,500,000, and take the whole of the earnings of the Atlantic cables at £750,000—there are ten cables—give the Mackay-Bennett cables their full proportion, which would be one-fifth; one-fifth of £750,000 is £150,000. From this must be deducted £50,000 for working expenses, at least £50,000 for reserve, which would only be £25,000 for each cable, whereas looking to the enormous risk and expenses of maintaining cables, it ought to be £50,000 for each cable. Then we must deduct the expenses of the repairing ship, say £10,000, which is a very low estimate, and £5,000 for duplexing the cables, making up altogether the sum of £115,000, which, deducted from £150,000, leaves £35,000, or 2¼ per cent. upon their capital of £1,500,000.

Now, assuming, as I think we have a perfect right to do, that this million and a half of money which they have put into their cable venture had been previously invested in American securities at from 6 to 8 per cent., but for the sake of argument we will take it at 6 per cent., which is a fair rate for American investments, the result is they would have received on this million and a half £90,000, as against the £35,000 they now get, which would be a loss of £55,000, or 3⅔rds per cent. upon their cable venture as compared with their previous investment. I may say also (and this may be valuable information for them) that since the direct cable was opened we have spent £116,000 for repairs, although we have been on the whole fortunate, and I think they can scarcely expect to be more fortunate than we have been, while the Anglo-American Company since their formation have of course expended a very much larger sum than this.

Now, I think, gentlemen, that we may reasonably suppose that Messrs. Mackay and Bennett cannot be very much in love with their new investment, and the question is whether they are likely to continue to work at a rate which gives them such an unsatisfactory return. Now, bad as it is for them, I am sorry to say it is in some respects worse for us. They had their cables made and laid at a time when they could be made much cheaper than they could years ago. That is in their favour, but we have against that all the knowledge and experience, and what I may term the goodwill from having done our work so well, so that in any competition I think we shall always get our full share of the business. But is it wise on their part or ours to work our cable system at a rate which is so very unremunerative? I have always said that wholesome competition is advantageous up to a certain point, but very dangerous when it comes to a point at which you might be deprived of a sufficient income to maintain

Digitized by Google

a thoroughly efficient service, and we are now in that position. We are not in a position at the present tariff to put by the reserve we ought to do, but fortunately in the past we have built up a good one, and you will find that we have been wise in securing such an important reserve as we now possess. The fact that at the present moment there are four cables in the Atlantic which are interrupted, in addition to some of the shorter sections, will show the absolute necessity of a large reserve fund, and although the prospect of repairing those cables is good, still there is always an uncertainty in repairing submarine cables; but there is one thing that is always certain, and that is, that the expenses of repairing are very great indeed. There is, I am sorry to say, amongst those I would call the speculative dealers in Atlantic cable property, a great desire to stop the further accumulation of a reserve, with a view to getting an additional shilling or two upon the dividend; but I say this is more on the part of the speculative holders than the permanent holders, and I hope the permanent holders will always raise their voices against any policy which would lead to a smaller reserve, and consequently a lessened security for their investment. Nor are we in a position to maintain the dividend we have hitherto paid if this reduced rate is to continue, as we can see no present prospect of any increase in the traffic at these low rates to recoup us for the loss which has been caused by the reduction. I think it may interest you to know that during the last two years the income from Atlantic telegraphy has been, for 1883, £939,000, and for 1884 £888,000, the tariff being 2s. per word during both years. Thus, you see, the receipts for 1884 show a decrease as compared with 1883, due to the depression in trade in the States and elsewhere. We have found the development of the traffic depends entirely on good or bad trade. At the most favourable times and tariffs the total revenue has never reached a million per annum. There is in fact only a certain amount of money spent in telegrams; the reduction of the rate does not sufficiently increase the number of messages; and, therefore, it is only by fixing such a rate as we consider not oppressive to the sender that we can hope to make it remunerative to our shareholders. I think we have proved this pretty well during the time that the present Board have had the conduct of this Company. The present rate cannot continue long, but still we are in no great hurry to move, at least, until our competitors have gathered a little more experience. But I think I may say, without much hesitation, that if we cannot agree to establish a rate which will be satisfactory to our shareholders, we must make such arrangements as will make it as bad for all parties concerned; but I wish to say that if we are obliged to go to a low rate for a time—and I wish this to be distinctly and fairly put to the meeting and to the public—the public will eventually have to pay for it, for we should by and by have to establish such a rate as would not only enable us to recoup ourselves for losses sustained, but also to return to our shareholders a fair dividend and provide a good reserve for the future. At the present moment our cable is interrupted, but arrangements have been made for its repair, and I hope, if we have anything like moderate weather, that we shall soon be in working order again. The interruption in our cable at the present time does not in any way interfere with our proportion of the earnings, as we are guaranteed by the Anglo and the other associated companies. That is one of the great advantages that accrue from the prevailing arrangements entered into with them. But were any interruption to occur to the Bennett-Mackay cables it would mean an entire loss of revenue to them. I have given you this very plain statement, as I think it desirable you should know, and that the public generally should know, and that Messrs. Mackay and Bennett in particular should know, something of the working of submarine cables based upon the long experience of a Board that has paid a great deal of attention to submarine telegraphy, and I have no doubt when they have learned their lesson as we have learned it, that they will find that it was more easy to get into a very unremunerative operation than to get up a successful enterprise of that description. I have now to move "That the report of the Directors, dated 27th January, 1885, together with the statement of accounts for the half year ended 31st December, 1884, annexed thereto, be, and the same are hereby, received and adopted."

Mr. Wm. Ford seconded the motion.

Mr. Jackson, while expressing his pleasure that the Board had maintained their loyalty to the principle of the renewal fund, thought that, under the circumstances described by the Chairman, they must look forward to somewhat reduced dividends. As the Board had a considerable amount of leisure at their command, they might, he thought, turn their attention and intelligence to the development of the traffic of Atlantic telegraphs generally without reference to competitive schemes or opposition. It seemed to him that it was not asking too much of such experienced gentlemen to suggest that they should do something in order that the Company should be in the van of progress. As one step in advance he recommended the institution of social telegrams. He said that the telegraph companies might and ought to consider not how high they could keep up their tariffs, but how by extra exertions and improvements they could increase the value of their property, and promote the interests of the public. He also referred to the great number of press messages carried by the Commercial Company.

Mr. John Newton asked if the Board had duly considered a question which he had raised on a former occasion—namely, whether it would not be better, in the interests of the shareholders, to reduce the denomination of their shares from £20 to £10, which he believed would give them a higher relative value in the market.

The Chairman: There is just one point in Mr. Jackson's remarks that I want to reply to—and I am always glad to reply to Mr. Jackson's remarks carefully, because I know that he takes a very considerable interest in the question, and any suggestion coming from a practical man we always like to meet in the way in which it ought to be met. In the first place, I have stated on previous occasions that I think there should be something done in the development of social telegrams, and I have no doubt that that will attract attention before long. But I think I stated a little time ago that there are four cables interrupted in the Atlantic at the present time, and instead of Mr. Jackson's idea being the case, that we are sitting counting our fingers just now, I assure you that the present time is probably one of the most anxious that the managers possibly could have. I see a gentleman here who has perhaps a greater experience in the practical working of telegraphic traffic across the Atlantic than any other man, and I know his time is fully occupied at present so as to keep up our reputation of being the best carriers, the quickest carriers, and the most certain carriers, when we are more or less what I call handicapped by the loss of these four cables. But you may rest assured that all our wits will be exercised to meet the traffic in an efficient manner. Another thing which Mr. Jackson referred to—namely, the parade in the newspapers of press messages coming through the Commercial Company, demands some explanation. It so happens, I believe, that that has arisen from a policy which we have considered a wise policy to follow; and while Mr. Bennett has always said that his newspaper line would be pretty well employed by newspaper telegrams, it appears that a very large proportion of the telegrams are sent at the rate of 5d. per word. Now, we thought if we found that we could employ our cables at 1s. 8d. it would be exceedingly foolish to employ them at 5d., and therefore we wished Mr. Bennett's cables to get the full advantage of this press system, so that while the press represents messages at 5d., our commercial messages stand at 1s. 8d. I do not mean to say, when the time comes round, and we are in a position to do what we desire to do, we shall not be too glad to cultivate the press messages. In the meantime we think it is better that they should carry them at 5d. while we are carrying ours at 1s. 8d. As to Mr. Newton's remarks, we have considered the question he has raised more than once. The Direct Company is more or less a distinctive Company, and I suspect somehow or other that the maintenance of the price as it is at present does not concern the general body of the shareholders, and we have very little to consider what the public outside our own shareholders may think about the matter. It is a question I am not prepared to give a decided answer to. If we were to reduce our shares to £10 and increase the number of our shares, they would stand in the market at about £4 10s., and I think we stand better at the present time by their being quoted at £9 10s. I think practically there is not much in it so far as the shareholders are concerned. But, still, it is a question that we do not say to Mr. Newton we will not look at. It is one that may come up again, and when it does you may depend upon it that it will be considered in the interests of the shareholders. I was just going to say, when I was reminded of the circumstance by our accountant, that our shares at present stand probably lower than they ever did. There is an idea abroad that we are what we call a one cable company, and if the cable should break anywhere our returns must cease. But our arrangement with the Anglo-American and other companies is that our cable must be broken for twelve months before it makes any difference in the amount that we take out of the general pool, and from our past experience we hope that a month or two will be the longest period that it will be interrupted; and therefore, although we stand as a one cable company, we are actually backed up, and have the advantage and security of seven other cables. Now, just to give you an idea of our position, our reserve fund, I may say, is worth to each shareholder for each share £5 11s. 6d.—that is to say, you have in your reserve fund alone, apart from your cable, £5 11s. 6d. which is on dry ground, well invested and secured. You have that in hand if your cable were to break to-morrow. Now, that is very satisfactory, and our reserve fund, if we continue to manage this Company as successfully, will show a continued and steady increase. But, while I have put things very plainly before you, I have no hesitation in saying that we are looking forward to a very great and important change in America, because a great country like America cannot be permanently depressed. The vitality of America is something enormous. The moment that begins to roll in the right direction you will find a great rebound, and telegrams will naturally follow. I do not mean to talk otherwise than as a plain and straightforward business man, and I expect Messrs. Bennett and Mackay to be the same; but I am very much mistaken if they had any other idea of going into this venture than to get money out of it, or they are not like other men, and I think when they are finding only 2½ per cent. return from it they will be the first to consider how they can improve that return on the capital invested. We make no approaches to them. We think it is better that they should gather their experience from the adversity of the situation. Mr. Mackay is a very rich man, but rich as he may be a million and a half is a large sum of money, and judging from his past I think his future will be to try and improve upon that 2½ per cent. And, gentlemen, I am sure he cannot benefit himself without benefiting us; and as we have a big reserve fund we are quite prepared to take a dignified position without being vindictive, and when the time I have foreshadowed comes round we shall benefit from the change which he may consider it desirable to make in the interest of the cables.

The resolution was then put, and carried.

Mr. Stokes proposed, and Mr. Jackson seconded, a vote of thanks to the Chairman, which was cordially passed.

The Chairman: Gentlemen, I have to thank you on behalf of myself and colleagues, and let me say this one word in conclusion. We have for the last seven years, I think, had the pleasure of meeting you every half year, and declaring to you not a large but upon the whole a fairly satisfactory dividend. We have, as I have said, in the meantime accumulated a very considerable reserve. Let us hope—and six months is a long time—when we meet you next time we may be able to congratulate ourselves on the prospect of recouping any little sum we may have lost during the present state of affairs.

The proceedings then terminated.

The Eastern Telegraph Company (Limited).

The twenty-fifth half-yearly ordinary general meeting of the shareholders of this Company was held on Thursday, January 29th, 1885, at the City Terminus Hotel, Cannon-street, London, under the presidency of John Pender, Esq., M.P.

The notice convening the meeting and the minutes of the last meeting having been read,

The CHAIRMAN said: I presume that you will take the report as read; and therefore, with a view to give you some little detailed information, I shall refer first to the figures in it. Our revenue for the six months ended the 30th September, 1884, amounted to £309,569, against, in the corresponding period of last year, £283,070, being an increase of £26,499. The greater part of that increase, something over £19,000, was derived from long Government and press telegrams, which have compensated us for the falling off which has taken place in the number of commercial telegrams. The Black Sea Company's traffic shows the sum of £2,023, against £623 in the corresponding period, which had to bear the cost of two repairing expeditions. During the six months under review we have had no interruption on the Black Sea line, and our revenue has consequently improved. Our receipts for traffic with India were less by £4,000 than for the correponding six months. To this I shall refer later on. The balance sheet shows that we have £3,498 in shares of the Mediterranean Extension Company, now in liquidation. This amount will, we expect, be realised at a profit before the next accounts are published. Interest on our balances and transfer fees have amounted to £540 more than last year. The working expenses of the Company were £284,907, against, in the corresponding half year of 1883, £80,849, or an increase of £4,058. This is mostly of an exceptional character. General expenses in London show an increase of £2,542. This is accounted for to some extent by the suit brought against us by the Central News Company, and other expenses. The working expenses at the stations show an increase of £1,994. This is accounted for by the increases and decreases in the following accounts under this head:—Salaries and wages at stations have increased by £2,045. We have opened during the six months four new stations—at Suakim, Piræus, Patras, and Katacolo. There are also six months' working expenses of our new station at Glasgow, against two months in the corresponding period of 1883. There is an increase in the travelling expenses of £1,369. There are the expenses under this head of forwarding clerks to the new stations, and expenses incurred in bringing witnesses home for the Central News action, their expenses in London during the trial, and sending them back to their respective stations. On the other hand there is a considerable decrease in the following items included in station expenses:—Maintenance and renewals of electrical instruments are £1,028 less, maintenance of land lines £436 less, repairs and renewals of furniture £180 less, and repairs to stations £433 less. Office expenses in London also show a decrease of £122; stationery and printing in London are £95 less, and expenses in connection with the cholera were £463 less, and the expenses of the issue of 4 per cent. Debenture Stock were £984 less. This accounts for the sums which I have named. The item of depreciation of cable stores shows an increase of £1,019. There is a new item of £500, being the proportion of the cost of the Suez-Benha land line and construction of cable tanks at Suez. It is absolutely necessary to keep at special stations tanks where we have cable, so as to keep it in a satisfactory state. The charge this half year for cost of the Lipari and Messina cables is £884, against £1,000 for the last five half years. The capital cost of those cables, namely, £5,884, has now all been charged to revenue. I may mention that this is a valuable item, and at the same time we have paid the whole cost of it out of income. The expenses attending repairs and renewals of cables are £31,189, against £29,520, or an increase of £1,669. Full particulars of the work done by our ships are given in abstract "C." After charging all expenses, including income tax on our net revenue, providing for interest on debentures and debenture stock, and preference shares, we are enabled to pay a dividend with bonus at the rate of 6 per cent. per annum and carry forward £30,364, against £13,679, in 1883. I need not give you the particulars of wages and other items. They are all more or less matters of detail. But I have given you pretty well the result in the figures which I have mentioned. And I think, ladies and gentlemen, I may congratulate you now on the report which I have placed before you.

There is one point referred to which I should like to mention—that is the traffic with India. We know very well from long experience of the telegraph system that increase or decrease in the number of messages transmitted depends more or less on the state of trade. There has been a very marked depression of trade in India and a very marked depression of trade in England. We at one time—last year—brought a large quantity of grain from India. The price of grain has been so low in this country, however, that that grain could not be moved this year, and having some connection with Indian railways myself it seems to me remarkable the enormous decrease which has taken place in the returns of traffic on the railways in India simply on account of the depression of trade there. Where there is depression of trade transactions in the way of telegraphy are very much less. Still, we present a good accconnt, notwithstanding this depression, and that good account arises from the state of things in China. I must not say that France is at war with China, as this would not be strictly correct; but there is fighting going on between China and France, as you see from the papers. The result is that this leads to a considerable amount of telegraphic communication being carried on, and we have derived benefit from it. But, looking at the depression of trade which has prevailed for a considerable time, I would rather trust to buoyant and active commerce than to war operations for a successful return on our enterprise.

The next business I have to refer to is one that is very interesting and of very considerable importance. When the report which is in your hands was printed we stated that all our cables were in perfect working order. To-day we have several cables interrupted. But, thanks to our arrangements and having our ships placed at a proper point to meet immediate repair requirements, I hope within a very short time indeed that we shall have our cables at work again. There is one point I wish to impress upon you more particularly—that, although we have breaks, we know where they occur, and have perfect confidence in being able to repair them. That, however, leads to this:—That we cannot do without ships, and it is important that we should have them placed at different points. Ships are more or less expensive, of course, and I have often said that they are most profitable to the Company when they are lying in dock doing nothing. Still we cannot do without them, and having them placed at proper stations enables us to repair the cables promptly when they are broken. We have also looked forward, probably beyond what some people would give us credit for. We have our system so arranged in the Mediterranean that if we had one, two, or three, or even four cables interrupted, we should still be able to conduct our important traffic with the Continent, and our large traffic with India, China, and Australia. We have—probably what you are not aware of—many alternative routes. During the present pressure of war intelligence and urgent messages on military affairs, we have been able to utilise our two cables from Alexandria to Malta and Marseilles, then from Alexandria to Zante and Otranto, from Zante to Trieste, and from Alexandria to Constantinople and Odessa. We have those four alternative routes to the Continent and Egypt, besides the line *vid* Gibraltar and Lisbon, which has been totally interrupted for the last few days. Therefore, ladies and gentlemen, we are now with many interruptions still doing our work in a way which the public can have no cause to complain of. There is one matter which I would like to refer to. I do not think it is out of place in doing so at a meeting like this. This Company is very largely indebted to those important messages which the correspondents of the different daily newspapers from time to time pass over our lines. We have received on more occasions than one telegrams that have cost the papers about £300. They have been sent by special correspondents of the papers at the seat of war. Yesterday brought us the very sad news of the death of two men, one of them pre-eminently great as a Press correspondent. I refer to Mr. Cameron; the other gentleman was Mr. Herbert. Mr. Cameron was the correspondent for the *Standard*, and Mr. Herbert for the *Morning Post*. Some of those around me had the pleasure of knowing those gentlemen. The public are greatly indebted to those men. We, as a body, are equally indebted to them. You see with what valour they have acted, and we know that the position they occupy is so different from that of military men who are crowned with glory by every success. But these gentlemen have to work inspired only with the knowledge that they are doing their duty to their employers and the public, and I look on them as greater heroes than those who have such brilliant rewards before them. I am sure you will agree with me in expressing regret at the great loss which the nation has sustained in the death of those two men [applause].

The last time I had the pleasure of addressing you I mentioned that we had connected Suakim with our system, and that Suakim was likely to be the opening to the Soudan. I referred to it because it was then generally supposed that any expedition sent from this country would go by Suakim to the Soudan. I am not prepared to give an opinion myself, but when I look at the hundreds of thousands of pounds that have been spent in going in that direction compared with the millions spent in going in other directions, and when my opinion is also the opinion of men of great experience, I simply say that I regret on many accounts that Suakim was not the road by which we approached the Soudan. I believe if the railway had been made it would have served a double purpose. It would have developed a new and great trade in that country. It would have prevented that slave trade which England has done so much to keep down, and in every respect I think the result would have been more satisfactory had Suakim been the way of approach to the Sondan. Still, all honour to those men, and although we are not deriving the same amount of telegraphic communication which we had at other times, we trust the result will be beneficial to the nation.

We have completed arrangements, and obtained now possession of the Mediterranean Extension Company. We have acquired it at a moderate price, and it now forms one of the links in our chain. We have done the same thing with the Direct Spanish Company, which is not in a very satisfactory state at present. But it is a link which may become a very important link in our system. I mean to say with regard to the Direct Spanish Company that we have acquired such an interest in it that we control it, and it will, I believe, become eventually a very important link in our system—at least, as a support to our system.

I have another matter to refer to, and you will excuse me if I speak at length, as I am very desirous that you should know everything we have done of any importance during the last half year. When I last addressed you I stated that we had made arrangements with the Greek Government which were of a very satisfactory kind. They were so satisfactory to the Greek Government that they proposed that we should make a still further connection with some of their outlying islands, and they offered us an extension for ten years of the subsidy they gave us, which will make it thirty-three years in all. The amount is £6,500 a year, and I believe the fresh extensions will cost us something like £6,000, so that, on the whole, that is not an unsatisfactory arrangement. We have also opened a station at Perim, in the Red Sea. One of our cables ran within a mile or two of this island, and an enterprising company established there a coaling station and applied to us to land our cable there. We have done that under a guarantee that our expenses will be paid, and we expect that the traffic from it will be something considerable eventually. The whole of our mercantile fleet is composed of steam ships, and they must coal somewhere, and what is the value of our great ironclads if we have not good coaling stations? That is going to become a great question of the day, and it is the interest of this Company, as far as we can, to

Digitized by Google

follow the flag—if we can follow the flag with the satisfaction of knowing we are benefiting our shareholders by so doing. I think I have gone through nearly all the points referred to in the report, but if I have omitted anything, or if there is any question that any gentleman would wish to put to me, I shall be very glad to answer it. In the meantime, I beg to propose "*That the report and accounts of the Directors to the 30th September, 1884, submitted to this meeting, be and they are hereby received and adopted.*"

The VICE-CHAIRMAN (the Marquis of Tweeddale): I beg to second that motion.

Mr. E. P. EVANS (a shareholder): I should just like to ask a question. But I may first say that the praise I could wish to bestow on those concerned in the management of the Company is beyond what I can express. We are largely indebted to them for the results they have shown. With regard to the question I am desirons of putting, is it necessary that our reserve fund should be kept at so large an amount? This has been accumulated out of profits, and belongs to the shareholders past and present, and to a certain extent we have earned as much profit as we can have. It appears to me that another additional shilling bonus would not have reduced the reserve fund except by £19,000, and would not have affected materially the substantial position of the Company. I really do think, unless we hear from the Chairman some explanation that this reserve fund should be kept at the large amount it at present stands at, that there might have been an additional shilling bonus given to us. Perhaps the Chairman will be kind enough to explain why this reserve fnnd is kept at so large an amount, and why is it necessary that that should be done?

The CHAIRMAN: Does any other gentleman wish to speak? I am very glad to have an opportunity of replying to this question of the reserve fund. Probably there never was a time in the history of submarine telegraphy when the question of reserve fund was likely to be more prominently brought forward than the present. I will refer to companies outside ourselves. There are four of the Atlantic cables interrupted at the present time. If they had not their reserve fund behind them the value of that property would go down in the market hand over hand. It is the reserve fund which is our backbone, and as we get a fair amount of interest on it you are getting not only the support of that reserve fund for maintaining the value of your shares in the market, but you know perfectly well that if any expenditure is required at any time you have the means to provide for it. In our Company we have a large reserve fund, and we have also a depth of water which does not give us any inconvenience beyond anxiety as to time required to repair any break that we may have. But if we had provided nothing to stand behind us it would have been bad management on our part.

Mr. WATKINS (a shareholder): Is the Company receiving any interest on the Direct Spanish debentures?

Mr. JOHN NEWTON (a shareholder): As to the earning capacity of the reserve fund—if you carried to revenue the interest you receive on your reserve fund we should have the satisfaction of seeing what is our exact revenue from that. But you carry some £10,000 a year—much more than that, in fact—not directly to reserve, but to the reserve fund. If instead of that you carried it to revenue account, it would show our profit larger and our income larger, and I think the interest should be carried directly to revenue instead of to reserve fund.

The CHAIRMAN: In reply to Mr. Newton, I think I have very often stated that we are very much in the hands of our accountants—public accountants, not the accountants at our office. I have also stated that our accounts should be kept by men perfectly independent of us; and there are certain principles which are recognised by those accountants, and they strictly follow them out. Mr. Griffiths has just reminded me that we have done exactly what Mr. Newton suggests, that we have placed to the credit of the reserve fund the income from the reserve fund during the year.

Sir JAMES ANDERSON: Mr. Newton wants the opposite.

The CHAIRMAN: Well, I think that is the most direct way of dealing with it; and you are a very good accountant, Mr. Newton, I know. We are, however, always open here to learn anything you can show us; and I will put you in contact with our accountant, Mr. Griffiths, and if you can convince him I don't think there will be much difficulty in convincing us.

Mr. SHERWIN: Those accountants are more or less the servants of the Company, and I do not think we should be thrown back upon them. I think the revenue might fairly be increased by carrying the interest from the investments of our reserve fund to the revenue account. I think we might fairly say that for the future the dividend on the invested reserve fund should be carried, as suggested by Mr. Newton, to the credit of the revenue account.

The CHAIRMAN: Our capital is over five and a half millions, and I think our reserve fund is far short of what it ought to be [hear, hear]; and therefore I am not prepared to make any departure from the policy we have established. I will give you a case in point. A gentleman has asked me now in regard to the Direct Spanish Company. We thought it desirable to get some control over that company. We purchased a certain number of their shares to get that control, and we placed upon the Board Sir James Anderson and another member of our Board, so as to look into affairs carefully. They found on examination that the reserve fund there was practically gone, and that there was no reserve fund to enable them to restore the cable. What has been the consequence? They have been obliged to suspend interest on the preference shares, because if they were to go on paying interest on those preference shares they might find the cable broken without a shilling in the locker to repair it.

Mr. NEWTON: I am afraid you have associated my name with a question I do not approve of. I approve of your increasing the reserve fund to a million, but I cannot approve of your not regarding that as the shareholders' capital. You may call it what you like, but I regard it as belonging to the shareholders. The question that I have raised is that all our revenue should come through the revenue account. All that I want is for it to be seen that we are doing so well as we are.

The CHAIRMAN: As I told you, it is entirely a matter of book-keeping, and if you can convince Mr. Griffiths you will not have much difficulty in convincing us. I think I have now answered all the questions, and I will put the resolution.

A SHAREHOLDER: I think the question whether you derive any dividend from the Direct Spanish Company has not been answered.

The CHAIRMAN: There is no dividend on the shares.

The SHAREHOLDER: Is there any dividend on the debentures?

Sir JAMES ANDERSON: Six per cent.

The CHAIRMAN: Six per cent. [He then put the motion for the adoption of the report in the usual manner and declared it carried unanimously.]

The VICE-CHAIRMAN (the Marquis Tweeddale): I have much pleasure in moving the next resolution, which is as follows:—"That John Pender, Esq., M.P., who now retires, be and is hereby re-elected a Director of the Company."

Mr. GEO. GARDEN NICOL: I beg to second it.

The VICE-CHAIRMAN put the motion and declared it was carried.

The CHAIRMAN: I am very much obliged to you for this further proof of your confidence. I think, taking all things together, from the beginning up to the present time, we may congratulate ourselves in being associated with a very prosperous company, and one which is likely to be still more prosperous. The next resolution is, "That the Most Honourable the Marquis of Tweeddale, who now retires, be and is hereby re-elected a Director of the Company."

Sir JAMES ANDERSON: I have much pleasure in seconding it.

The CHAIRMAN put the motion, which was carried.

The MARQUIS OF TWEEDDALE: I beg to thank you for the honour you have done me.

Major LESLIE: Mr. Chairman and gentlemen, I have much pleasure in proposing the re-election of our auditors, Mr. Henry Dever and Messrs. Quilter, Ball, and Co., and I trust that they will always have so good an account to render us as on the present occasion.

Mr. GIBB: I beg to second that.

The CHAIRMAN: The motion is, "That Mr. Henry Dever and the firm of Messrs. Quilter, Ball, Crosbie, Glegg, and Welton be, and are hereby elected auditors of the Company for the current year, with a remuneration of £100 each. [He put the motion, and declared it carried unanimously.] I think, gentlemen, that closes the business of the meeting.

Mr. GIBB (a shareholder): I rise to propose the usual vote of thanks to the Chairman, Directors, and staff for their services. We may congratulate ourselves on having such a good account.

Mr. GRIFFITHS: I beg to second that. The public reputation in which our Company stands is greatly due to the able conduct of the gentlemen who have managed the affairs of the Company during the past half year. At this late moment I will not detain you, but I am sure the very courteous replies given by the Chairman and the full explanation he has afforded must convince you that he is entitled to the gratitude of those for whom he has laboured so hard.

The SOLICITOR (Mr. Burt) put the motion and declared it carried unanimously.

The CHAIRMAN: On behalf of myself and colleagues I have to thank you for this renewed evidence of your confidence.

The proceedings then terminated.

PHYSICAL SOCIETY.—January 24.

Professor Guthrie, President, in the chair.

Messrs. J. Rose Innes, A. Howard, and A. M. Worthington were elected members of the society. Some "Lecture Experiments on Spectrum Analysis" were shown by Mr. E. CLEMENSHAW. The chief point in these experiments was the production of a brilliant light without the use of the electric arc. A small quantity of a solution of the salt to be experimented on is put into a flask, in which hydrogen is being evolved by the action of zinc upon dilute sulphuric or hydrochloric acid. The bottle is provided with three necks, one being fitted with an acid funnel, one with a jet, and by the other is introduced a current of coal gas, or better, of hydrogen, by which the size of the flame can be increased and regulated. The jet, which is about one-eighth of an inch diameter, is surrounded by a larger tube by which oxygen is admitted to the flame, the result being a brilliant light giving the spectrum of the substance, which is carried over mechanically by evolved hydrogen. The spectra of sodium, lithium, and strontium were shown upon the screen; and the absorption of the sodium light by a Bunsen flame containing sodium was clearly seen.

An instrument to illustrate the conditions of equilibrium of three forces acting at a point was exhibited by Mr. WALTER BAILY. This instrument consists of a circular disc of soft wood, from the back of which an axle projects. The disc is provided with a graduated circle, and its centre marked by the intersection of two fine lines upon a small mirror. Three compound threads, each consisting of two threads connected by a short piece of elastic, are knotted together, the free end of each being fastened to a pin. Two of these pins are stuck into the disc at such a distance from the centre that the knotted ends cannot reach the centre without stretching each thread, and the remaining pin is then adjusted so that this condition is fulfilled. There are now three forces in equilibrium acting at the knot. The angles between their directions are obtained from the leadings of the graduated circle where it is crossed by the threads. To determine the magnitude of these forces the axle of the disc is held horizontally and turned till a thread is vertical, the pin is then removed, a scale-pan attached to the end of the thread, and weights added till the knot is brought back to the centre. This is repeated with the other threads. It was found possible to show the proportionality of the forces to the lines of the opposite angles with an error not exceeding one per cent.

The Anglo-American Brush Electric Light Corporation.

The ordinary general meeting of this Corporation was held at the Cannon-street Hotel on the 4th inst., under the presidency of the Right Hon. Lord Thurlow.

The SECRETARY (Mr. Emile Garcke) having read the notice convening the meeting,

The CHAIRMAN said it was a great pleasure to him and, he thought, to all his colleagues, to be able to meet the shareholders on that occasion under, what he hoped they would all admit, were certainly more favourable circumstances than those which existed a year ago. The present year had undoubtedly been one of many vicissitudes, not all of them of a very pleasant nature. Trade certainly had not revived to the extent that was anticipated, and all commercial interests had necessarily suffered more or less from this cause. It was not to be expected that a new industry like electric lighting could have formed any exception to this rule ; nor had it done so. The fact was that people were waiting for better days before they embarked in what would at first entail a large outlay for capital account. He thought if they took all these circumstances into consideration they would consider that the business transacted by the Company this year had not been altogether of an unsatisfactory nature. They had held their own as well as any of their rivals and competitors. They began the new year with important machines, with increased economy in the manufacture, and with widely extended appreciation both on the part of the public and of the Government, and especially the Admiralty, for whom they had executed and were executing important orders. He thought, therefore, that he might say that they began the new year under very favourable auspices. In addition, they must remember that the Company's shops were still full of remunerative work, and that they had by no means an unimportant balance at their bankers. Apart from manufacturing improvements and details, he thought it would be admitted that the two salient features in the Company's policy last year had been, first, the further concentration under one roof of all the operations that were necessary in the construction of dynamos and lamps, which hitherto were scattered throughout different buildings several miles apart. The result of these removals had naturally been a complete reorganisation of all their machinery and a very great saving had accrued both in labour and steam power. In doing this they had had to enter into a very careful analysis and re-valuation of all their plant, which had been done by very competent people, with the result that it enabled them to transfer a great deal of machinery which had now become superfluous to stock account, from which it could be taken and re-established in the works or disposed of as favourable opportunities might occur. The second salient point in their policy, he maintained, had been the progress they had made in absorbing the subsidiary companies. In his mind there could be no question that the original policy of the Corporation in founding subsidiary companies was an eminently sound one. Nothing, he thought, could have been sounder than to have had substantial local companies to work the provinces and the metropolis, and become the best customers of the great central manufacturing Corporation. But that dream was not destined to be realised ; and as a matter of fact, the reason for the existence of the subsidiary companies passed away almost as rapidly as it had arisen. Under these circumstances, he maintained that the policy the Corporation were pursuing in absorbing all these companies as opportunities might offer on terms favourable to all concerned was at once the most generous and most judicious. The report stated that they had come to terms with and had absorbed the Great Western and the Brush Midland Companies. The terms made were eminently satisfactory to all parties concerned. The conditions of amalgamation or absorption were not arrived at without lengthy discussion and careful consideration, and he thought he might say without making concessions on both sides. The Corporation had acquired by these amalgamations, besides cash, very valuable assets, important opportunities of extending their manufacture and sales. They had also recovered for a sum just under £6,000 their licenses over 23 counties in England and Wales, for which the Corporation received previously £27,730 in cash. This £6,000, too, would be paid in shares by the Corporation. The exact amount of new capital they would be called upon to create could not be quite accurately stated. It would depend on circumstances which he need not enter into, but there could be no doubt that the total amount of issue would be considerably short of the maximum mentioned in the report. On this new capital they would have to look to pay dividend, but it would be in a good dividend year, he maintained, an additional charge which would not be felt, and in a bad dividend year it would certainly be unimportant. With regard to paragraph 8 in the report—which he considered second to none in importance—it dealt with the steps they had taken and were taking to procure a complete revision of the Electric Lighting Act of 1882. The intention to ask the Government to review an Act so recently passed was an undertaking of considerable magnitude, but he was sanguine of success, as they had public opinion on their side. They had been met very frankly by the Edison-Swan Company, by Mr. Hammond, and Mr. Crompton—in fact, by all the leading men connected with electric lighting. They had set aside any differences they might have had, and had made common cause to obtain the removal of the fetters of 1882. The Act of 1882, he thought, must be cautiously approached. There was no doubt in his mind whatever that the provisions it contained acted most prejudicially and most unfairly on this new industry. At the same time, he was one of those who thought and believed that when the Act was passed its authors were really anxious to encourage the new industry. None the less was he one of those who held that on that occasion Parliament mistook its duty, which certainly was to have fostered by every means in its power, and not to have throttled a new discovery, which was destined to confer such benefits on mankind, and he thought their best chance of arriving at a satisfactory conclusion was to argue the question with calmness and without passion. They must remember the circumstances under which the Act of 1882 was passed. The science was in its infancy. The only thing that was patent to the public and the Legislature was the rash gambling spirit that prevailed at the time, and which the Legislature naturally deemed it its duty to curb and discourage to the utmost extent. In looking back to that time he could not help feeling that the attempt made to frame an Act which should not require amendment, and which should be adaptable to the advancement of science, as these improvements should be made, was almost superhuman, and it could not be wondered at that it had failed. He thought, as regarded this Act, that so far from giving rise to the recriminations and aspersions which were so freely cast upon it, it would in due time take its place amidst those pioneers of legislation of which the British Parliament had produced so many examples. Strong in their conviction, they approached Mr. Chamberlain, who received them not merely courteously, but with an evident desire to lend an unprejudiced ear to what they had to say. They had the good fortune to get their case stated by Sir Frederick Bramwell, and finally they were requested by Mr. Chamberlain to draft clauses of amendments for the consideration of the Board of Trade. They were still engaged in that task, with the assistance of Sir Frederick Bramwell and many other distinguished men, and he for one looked forward with confidence to the recognition of the justice of their demands, and to the removal of what certainly were the most onerous conditions ever imposed on the application of capital to a British industry. As to the financial condition of the Company, the year's work had shown a gross manufacturing profit of about, in round figures, £23,000. Of that sum £16,723 were absolutely on manufacturing account, and he desired to say that that figure had been made the subject of a careful scrutiny both by themselves at the Board, by their accountant, and by their auditor, and it might be relied upon as substantially correct. The other figure of £6,000 odd, which appeared in the accounts as other receipts, as sundry profits other than gross profits on trading—that figure represented items of what, perhaps, other companies might consider of an unusual character. But they were items fairly belonging to the revenue account, and one of his reasons for saying so and insisting upon the point was that they were items which, in a concern like theirs, would recur, and must recur, year after year, to a greater or lesser extent. They belonged distinctly to revenue and not to capital. And this gross total of £23,000 of profits would have been much larger by many thousands of pounds had it not been for an unfortunate falling off in orders which occurred during the summer months of 1884. Their net profit after deducting the standing charges and other things that had to be taken out of this sum stood at £5,743. This would have been larger by £2,000 had it not been for the proverbial uncertainty of the law, which was strikingly exemplified in the Muir law suit—a case which they would remember was one very unfortunate to them all as shareholders—but it was a case for which the present management was not responsible. The former management ordered of that firm a most unwieldy and extravagant machine. It was contracted for to be supplied in eight or nine weeks. It was not ready to be delivered for nine months, and it was not till greatly after that time that it was delivered. No wonder, therefore, that when the new Board found they did not want this machine they refused to take delivery of it. The thing went into the law courts, and the Corporation got several decisions in their favour, but owing to the uncertainty of the law, to which he had alluded, the final decision had been given against them. He would not have referred to this subject had he not desired to say that no item of that kind could enter into the accounts of 1885, as all the law charges for 1884 had been fully met and provided for, and they stood not only free from all litigation, but he believed (it was a rash thing to predict) without any chance of any appeal against any decision given heretofore in favour of the Corporation. Whatever litigation, therefore, which might be in store for them in 1885 would be honestly incurred in that year. The first duty of course in appropriating a financial margin was, as the shareholders were aware, to clear off an adverse balance if they unfortunately had one of the year before, and their accountant had done so in this balance-sheet. He left it not as a matter of option, but as a matter of necessity, and that reduced the sum they were called upon that day to appropriate to £4,127. That sum would be sufficient to enable them to declare a dividend at the rate of 2½ per cent. on the paid-up capital of the Corporation for the past twelve months if they desired to do so. That, however, was not a course which the Directors recommended for their adoption. They advocated the course sketched in the printed account attached to the balance-sheet, namely, to write off £1,500 from patents account, to write off £1,000 from goodwill and licenses recovered over twenty-eight counties in England and Wales, and to carry forward the balance of £1,627 to the credit of the ensuing year. They felt sure that that was a course which would give confidence to all, and would be acceptable to the great body of shareholders, and they also felt that it was a course that would be most consistent with the real interests of the Corporation. At the same time he did not wish them to lose sight of the fact of their having turned and returned to the position of a dividend earning Corporation. He trusted they would support the suggestion in the report of electing Mr. Braithwaite as a director of the Company. That gentleman was formerly chairman of the Great Western Electric Light Company, and he took, and always had taken, a great interest in electric lighting, and he was eminently qualified for the position of a director of the Corporation. He eulogised the services of the staff, referring in particular to the eminent services of the general manager and engineer (Mr. Frank Wynne) and of the secretary. Since he had been in the room a little piece of paper had been handed up to him, which he thought they would admit was of an encouraging character. It could not fail to be encouraging, being, as it were, a straw which showed which way the wind blew. He heard that one of the first

Digitized by Google

and most successful English gas companies (the name of which he was not at liberty to mention) had asked for powers to raise £300,000, which was to be used for electric light purposes. He concluded by moving the adoption of the report and accounts.

The VICE-CHAIRMAN (Mr. John Scudamore Sellon) seconded the motion, remarking that, after the supplementary explanation given by Lord Thurlow, there was very little left for him to say beyond emphasising, as he earnestly wished to do, what had often been foreshadowed, namely, that with the advance of the electric light which was inevitable now that its advantages and practicability were realised, and with the prospect that the ever-to-be-condemned Electric Lighting Act of 1882 would be remodelled upon lines of intelligence and justice, the property of the Corporation would stand out well in the foreground as embodying certainly the three great essentials to success, namely a good and well proved system, the highest class of workmanship, and a most excellent executive staff. The Board had had uphill work to arrive at the present condition of things, but he could now with confidence ask them to feel that if there was success in this important branch of industrial work and scientific development the Corporation would both deserve and command it.

Mr. W. ABBOTT referred to the expenses, which he thought were heavy, in obtaining the results arrived at.

Mr. F. W. REYNOLDS trusted that no new patents had been acquired, and he thought, if they did acquire any patents the payments should be by way of royalty. On the whole, he thought the balance sheet very satisfactory, but he thought there was not the slightest chance of the electric light making any great progress until there was some improvement in the general volume of business of the country.

Mr. HALL generally concurred with the remarks of Mr. Abbott. He thought that certain accounts included in the present year should have been included in the last year, as there was no use in endeavouring to make bad look better.

The CHAIRMAN, in reply, said that Mr. Abbott had scarcely been fair in his remarks as to the expenses. As a matter of fact, the total charges for 1884 had been £14,693, as against £26,533 last year, showing a diminution of the total normal charges in one year of 45 per cent. He certainly did not consider that a trifling matter. He mentioned various economies which had been effected, and said that there had been an increase of 120 per cent. in the volume of their work for the previous year. They had not acquired outside their works any more patent property last year, and the increased charge which was referred to in that item was for the cost of the developments and improvements made in their own works in connection principally with the new armature, which was of such enormous advantage to them, and which had achieved such excellent results. They had also been at some expense in improving the ratchet lamp. As to paying an interim dividend he would be the first one to hail such a proposition with delight, and if things went on well there was no reason why there should not be one. This was a matter, however, which rested with the public and the success of their endeavours to obtain legislative relief in the Act of 1882.

The motion was unanimously adopted, and resolutions were afterwards passed re-electing Mr. H. C. Gibbs, Mr. J. I. Courtenay, and Mr. Wm. Ladd, F.R.A.S., to their seats at the Board; appointing Mr. J. B. Braithwaite, jun., a Director; and re-electing Messrs. Cooper Brothers and Co. Auditors.

On the motion of Mr. ABBOTT, a vote of thanks was passed to the Chairman, and the proceedings then terminated.

South African Brush Electric Light and Power Company (Limited).

A general meeting of this Company was held on Wednesday at the City Terminus Hotel, Cannon-street, Lieut.-Colonel G. Coxon in the chair, for the purpose of receiving the audited balance-sheet of the Company, made up to the 28th of January, 1885.

In opening the proceedings,

The CHAIRMAN said the Directors did not think it was necessary for them to print the accounts. They had been made up to the latest possible date, had been duly audited, and were on the table for inspection by any of the shareholders. What he might term the "cream" of the document lay in a few items, which he would quote to the proprietors. In the first place, they had £10,683 4s. 2d. at the bank, a bill due on the 13th of June, 1885, amounting to £1,500, and there was an outstanding account with the Town Council of Kimberley, which, he might add, was undisputed, amounting to £1,680. The Directors had instructed their representative to recover the sum, and they expected very shortly to hear of it having been paid. In addition to this, there were sundries amounting to £235, making the gross assets £14,098 0s. 2d. The debts included the estimate of expenses up to the end of the 28th June, £494 5s. 1d.; in assets for distribution, less, of course, the expenses of liquidation, £13,603 19s. 1d., which would run to about 14s. per share.

The meeting having been made special,

The CHAIRMAN proposed the following resolution:—"That the Company be wound up voluntarily under the provisions of the Companies Acts.

Mr. T. DICKSON seconded this, and it was agreed to, whereupon,

The CHAIRMAN proposed the appointment of Mr. T. J. Seel (the Secretary) as sole liquidator, with all the power which could be conferred on a liquidator under the Companies Acts, with a fee of 100 guineas. He said he thought that gentleman was so well known to all the shareholders that his proposal required very little apology from him. He alluded to the great difficulties Mr. Seel had had to contend with, and said he thought they were very much indebted to him for the manner in which he had conducted the business placed in his hands.

Mr. PORTER RHODES second the resolution.

Mr. DICKSON said he was sorry to have to differ from his colleagues. He had had considerable experience as a liquidator, and he was of opinion that the liquidation should be conducted by a gentleman who had a substantial interest in the undertaking. The Secretary was not a shareholder, and did not represent the interest of the Company, as would a gentleman who held shares. There was no means of telling what might crop up during the liquidation. They might think it was all plain sailing, but they might be mistaken. He thought a member of the Board should have the appointment, at the same time reminding the shareholders that directly a liquidator was appointed they parted with their "personality" altogether.

Replying to questions asked,

The CHAIRMAN said they were not entirely clear of the parent company, inasmuch as in assigning to Kimberley and Cape Town the patents they had unfortunately done so without assigning the responsibility which still attached to them. The parent company would still consider them responsible for any shortcomings of the Company to which they had assigned the patents; but they had no reason to believe that the parent company would be unreasonable in these matters.

The resolution was then carried subject to confirmation fourteen days from the date of the present meeting.

In thanking the proprietors for having appointed him, Mr. SEEL said it would be his duty as soon as the resolution was confirmed to distribute the assets amongst them as speedily as possible. He saw no reason why the distribution and dissolution of the Company should not be speedily effected; indeed, the distribution to the shareholders should certainly take place within three months of the confirmation of the motion.

A vote of thanks was passed to the Chairman, and the proceedings terminated.

KING'S COLLEGE ENGINEERING SOCIETY.

On Tuesday last, at an evening meeting of this society, Professor W. G. Adams, F.R.S., gave a lecture on "The Electrical Experiments at the South Foreland," of which the following is an abstract. The lecturer said:—

A person walking from Deal to Dover would find when he approached St. Margaret's Bay that besides the two permanent lighthouses of the South Foreland there were three other towers, or tall windmills of singular construction without their sails, labelled A, B, and C, as though they were intended to teach the alphabet to some giant race. These towers are three experimental lighthouses for testing the several modes of lighthouse illumination. The "A" tower is designed to give the light of the electric arc on one or more of three tiers or stages, one above another. The "B" tower gives the gas light according to the system of Mr. Wigham, on four stages; and the "C" tower is supplied with oil lights, and sometimes with gas lights, on the system of Sir J. Douglass, on three several stages. The lights are spoken of as single, biform, triform, or quadriform, according as one or more of the stages of a tower supply light at the same time. Thus the light from all three stages at once of the "C" tower when supplied from oil would be described shortly as "triform" oil, known as the high and low light. The two permanent lighthouses, about 450 yards apart, have been supplied with the electric current since 1869 from Holmes' magneto-electric machines. In clear weather one machine is usually employed for each light, the second machine being ready for use in case of accident or in foggy weather. The machine contains 48 compound horse-shoe magnets, each weighing 44lb., arranged in circles with their poles toward the centre in seven vertical planes. There are 96 helices or coils of copper wire fixed on six wheels, which revolve so that the coils pass in front of the poles of the magnets—*i.e.*, between the poles of parallel rings of magnets. The ends of the wires of the several helices are joined alternately to two cylinders of metal or collectors on the axes against which the brushes rub which take the current to the external circuit. As a coil passes from a south pole to a north pole there is a current in it in one direction which is reversed as the coil goes from a north pole to a south pole, so that in one revolution there are sixteen reversals of the current, and the machines are driven at 400 revolutions per minute. Each machine absorbs about 3·2 horse-power, and with a mean electromotive force of 29 volts supplies a mean current of about 28 amperes and gives a light of about 1,520 candles. The E.M.F. on open circuit is about 75 volts. Two Holmes machines when joined to the same external circuit with a mean E.M.F. of 31 volts will supply a mean current of 53 amperes. Regarding the product of these numbers as the average power of the machine, we get 1,640 watts or units of power from the two machines to 3,000 candles. This is the permanent arrangement at the South Foreland for lighting shipping in the Channel. The 1,500 candle-power light is intensified by lenses and by prisms, and gives horizontal belts of light extending over the sea for a considerable arc, the high light illuminating about 180 degrees of arc. The engine room, in which the magneto machines are placed, is about half way between the two permanent lighthouses. The chief interest of the experiments which have been lately carried on is gathered round the three experimental towers, A, B, and C, for here are found the largest and most brilliant lights, whether electric, gas, or oil, which have ever been employed for lighthouse purposes, and as you may have seen occasionally in the daily papers between two of them the rivalry is very keen. The object of these measurements is to determine the brilliancy and the best arrangement of these lights, their efficiency, and the cost of their production. For the measurement of the lights themselves, without the lenses, a photometric gallery, some 400ft. in length, has been built on the

Digitized by Google

cliff, near the engine room. This is supplied with gas from temporary gas works on the cliff, and with electric current by leading wires from the engine room, in which all the magneto machines are placed.

Professor Adams then proceeded to describe the methods of measuring several lights by means of the Bunsen disc and the star disc photometers, and also by the shadow photometer, taking for the standard a Douglass lamp with colza oil, and with a slit of given size used, called the Merthven slit, from which measurements are taken. The Bunsen disc and shadow of photometer are fairly suitable for oil and gas lights, but when we come to the electric light, it is found blue in comparison with the yellow light of gas or of the 6-wick oil light. Experiments were then made to determine the illumination given by the electric light by means of a dispersion photometer, using a convex lens as in the method proposed by Dr. Hopkinson, by which it was shown that within a distance of 10 feet of the electric arc, giving a light of 16,000 or 20,000 candles, the light may be compared with an ordinary standard of one or two candles, the difficulty arising from difference of colour being got rid of by using ruby glass and other coloured glass, or solutions such as ammonia sulphate of copper, in front of the eye of the observer of the Bunsen disc, to determine how much red or how much yellow or green or blue light is present in the light of the electric arc as compared with the amount of the same kind of light present in the standard of light chosen for comparison with it.

General Description of Lighthouse Arrangements.—Taking the various kinds of light in their chronological order, we have first the oil lamp, which, in its present improved state, consists of a number of concentric burners, with wicks arranged as in the duplex lamp, the number of wicks varying from 1 to 6, and in some recent lamps to 7 and 8. The flame of the 6-wick lamp, which is commonly used, is contracted by means of a properly curved glass chimney to 4·33in. in diameter, at the level of the centre of the lens, which sends out a slightly divergent beam to the horizon. The horizontal divergence of the beam amounts to about 6°, when the centre of the light is placed accurately in the focus of the lens. The light given by the 6-wick burner, from measurements made at the South Foreland, will probably be found to be about 800 candles. In consequence of the small divergence of this beam, it will give a light at some distance on the sea equal to the illumination from a source of 2,000 candles where there is little more than twice the same divergence. The Wigham gas burners consist of a number of separate gas burners arranged in rings and put on in sections with open spaces between for the supply of air. Imagine a number of seperate burners on one arm bent into the arc of a portion of a circle, and these supplied ring after ring, the inner being slightly raised above the outer rings, and you have the Wigham arrangement of gas burners. Beginning from 28 jets for the lowest light required, increased illumination is obtained by adding outer rings of jets by 20 at a time up to 108, which give a breadth to the gas flame of 11 inches at the level of the lens. Hence the light from this burner is greatly scattered, and the horizontal divergence of the beam from the lens was found to be over 14 degrees. The light given by the 108 jet gas burner, as measured at the S. Foreland, will probably be found to be about 2,000 candles.

We now take the electric light as given forth from the "A" Tower. The current is generated by alternate current magneto machines of the largest type made by De Meritens, having 60 permanent magnets arranged in five rings of 12 magnets and 24 coils of each ring of the revolving armature.* After describing the method of measuring E.M.F. (1) by the electrometer (2) by Cardew's voltmeter, and the current by a Siemens electro-dynamometer (a fuller description of which will also be found in the number of *The Electrician* just referred to), continuing, the lecturer pointed out the influence of high resistance on the distribution of electrical energy in the circuit. That, whereas only an E.M.F. of 30 volts is required at the extremities of the arc, the E.M.F. at the machines is increased to 45 and even 50 volts with a corresponding diminution of current in consequence of the high resistance of the leads to the tower 300 yards away. Thus the current of 220 or 230 amperes, which can be obtained through an arc from one De Meritens machine is reduced to 130 amperes, and on employing two machines in parallel circuit for one arc the current is reduced from more than 400 amperes to about 180 amperes. In spite of this, the electric energy from the De Meritens machine is about ten times the electric energy from the Holmes machine, with a corresponding increase in the light given forth from the arc. From the arc from one machine an illumination of about 16,000 candles may be obtained, and from two machines from 20,000 to 30,000 candles, the machines sometimes being used to supply a single arc, and sometimes two arcs in series in the biform arrangement of the lights. The various experiments of 19th July, 1884, were then described, when, for the first time, two alternate current machines were set running together with their brushes united, and then the belt thrown off one machine, which continued to be driven as a motor by the current from the other machine. A full description of these experiments will be found in our issues of December 6 and 13.

* Further description of these machines will be found in our issue of 6th December, pages 75–76.

THE DRAWBAUGH TELEPHONE CASE.

AMERICAN BELL TELEPHONE COMPANY AGAINST THE PEOPLE'S TELEPHONE COMPANY ET AL.

(CONTINUED FROM PAGE 192.)

The third class of witnesses are those who identify more or less positively one or more of the several exhibits as the instruments used by them or which they saw used by others prior to March 7, 1876. Exhibits F and B are identified by the following witnesses:—Brooks saw them in 1874; Smyser, in 1872; Eberley, before Dec., 1870; Wagner, in the fall of 1874; Freese, in 1869 or 1870; Yetter, about Christmas, 1875; Fry, spring of 1875; Carl, in 1870; Scherick, in 1869; Balsley, between 1870 and 1874; Good, before 1872; Kahey, in 1871 or 1872; Schettel, about 1872; Nichols, in 1875; Renneher, in May, 1875; Weber, late in 1874; Stephen, before 1875; Shireman, about 1872; Hawn, about 1872; H. B. Eberly, in May, 1873; J. C. Smith, between April, 1872, and April, 1873; Sternberger, in October, 1871; Fetterow, in April, 1876; Halsinger, prior to 1876; Shoop, in 1869; H. F. Drawbaugh, in 1872; Zimmerman, in 1871; Bates, in 1874; Guistwent, in July, 1870; Hale, in fall of 1873; Stone, in June, 1871; Free, in June, 1872; J. A. Oyster, in June, 1875; Harman K. Drawbaugh, in July, 1871; J. B. Drawbaugh, in 1869; G. W. Drawbaugh, in 1870; Lenseman, in July, 1881; Fisher, in 1868 or 1869; Hubler, in fall of 1873; Updegraff, in 1874; W. H. Decker, in 1873; and a number of other witnesses saw one of these two exhibits.

The identification of Exhibits C, I, and A is made by a smaller number of witnesses. Some of them think they saw C in 1870 and others at various dates after that, and as late as March, 1876.

One of the witnesses thinks he saw I in 1871, the others locate the occasions in 1873, 1874, and 1875. Some of the witnesses think they saw A as early as 1872, one of them in 1870, but most of them saw it, they think, in 1875.

Exhibits E and D resemble each other very closely in appearance, and most of the witnesses produced to identify them saw both at the same time. They locate the time as follows:—Fry, labourer, in May or June, 1875; Fry, farmer, in April, 1875; Bayler, in June, 1873 (Ex. D); Springer, after April, 1876; Shettel, about 1875; Shoop, after February, 1877; Musser, in June, 1876 (Ex. D); Milliard, in 1875; Holsinger, in summer of 1875; Shoop, in 1874 or 1875; Bates, between 1874 and 1877; Dellinger, in March, 1876 (Ex. E); Gustweit, between 1870 and 1876; Bowen, in September, 1878; Hale, in fall of 1875 (Ex. D); Michael Dellinger, in November, 1877 (Ex. D); Harman K. Drawbaugh, in January, 1875, and helped put up wire for them; J. B. Drawbaugh, prior to Jan. 26, 1875; George W. Drawbaugh identifies all the exhibits as seen by him some time between 1871 and 1878; Musser, in 1876; Smith, in 1872 or 1876 (Ex. E); Updegraff, in May, 1876 (Ex. D); J. H. Smith, in May, 1876 (Ex. D); Decker, in 1874 (Ex. D); Vannasdale, in February, 1875; Evans, in fall of 1875; Mrs. Erb, in fall of 1875; S. E. Evans, in fall of 1875 (Ex. D); M. E. Evans, in fall of 1875 (Ex. D). Some of the witnesses who identify exhibits identify the whole series. Other witnesses besides those named identify one or more of the exhibits as seen by them at times subsequent to the date of Bell's applications for his patent. Some of the witnesses who identify one or more of the instruments exhibited to them by Drawbaugh as the Exhibits F, B, or C, saw or used them in 1875 or 1876. Among these are the following, to whose testimony a reference will be made:—

Mr. Springer testifies that he repeatedly talked and listened with Drawbaugh through the instruments after the 1st of April, 1876, using Exhibits F and B as the instruments. Mr. Musser testifies that he talked through F and B in June, 1874; but the proofs show that this occasion was as late as in the summer of 1876. Mr. Moore, who is produced to show that Drawbaugh applied to him to acquire an interest in the invention, testifies that the talking machine which Drawbaugh produced was Exhibit B. This was in May, 1875. Mr. Bayler testifies that he talked through F and B in 1873, but the proofs show that the occasion was between 1875 and 1877. Mr. Nicholas locates the middle of January, 1875, as the time when he saw Exhibit B in use.

That the talking machines referred to by the witnesses were electric instruments is clearly established. Drawbaugh testifies explicitly that they were always used with a closed circuit and without breaking the current, some of them being battery telephones and some magneto-telephones. He always represented them as actuated by electricity to those to whom he explained or described them, and claimed his invention would supersede the telegraph. His assertions show them to have been electrical instruments. He stated to the witness Shank, "It was the greatest invention ever known. If he had the means to go on with it they could talk, or rather be a time to come as to talk to the old country same as we can talk here;" to Zacharias, that "he could run it out for miles, and parties could talk in at one end and be heard at the other end, the same as persons in a room together;" to Smith, that "parties between Harrisburg and Philadelphia could communicate as if they were speaking together; there would hardly be any limits;" it was an "instrument to convey the voice, to supply the place of the telegraph;" to Smyser, that it would work "from here to California;" to Fry, that one "can talk as far as the wire goes;" to Carl, that "he could hear a man talking from that place to New Cumberland or Harrisburg, and understand distinctly what he said;" to Sherick, that it was "better and handier than the telegraph; that you could just talk through it in place of writing;" to Blasley, that "by attaching two wires you can hear it a way off; the telegraph is nowhere with it;" to Kahney, that "he could talk the same for miles as he could for short distances;" to Shettel, that "if he had a wire from the shop in connection with the telegraph wires at White Hill he could talk to

Digitized by Google

Mechanicsburg by having a machine there or an instrument in the office; that it would be better than telegraphing, and that it would be worth a great deal of money;" to Reneker, that "he thought he could make it that he could talk through to Harrisburg; he thought they would take the place of telegraphing;" to Weber, that "it beats all the others of my inventions; he could carry sound, or rather talk, as far as Shiremanstown;" to Hawn, that "he would be able to operate, that a man preaching in New York, that a congregation in Philadelphia would hear the same sermon;" to Kahney, that "he could just as easy speak ten miles as one, or any distance he would choose to;" to Rupp, who was there with Hammacher, that "it was worked by electricity; would take the place of the telegraph, and that he could make it so that he could talk to San Francisco;" to Musser, that "he was going to make a machine to talk from Harrisburg to Philadelphia, and it would be a cheaper and quicker way than telegraphing;" to Smith, that "he believed they could talk for a hundred miles;" to Fetterow, that "I could speak ten, fifteen, or twenty miles, or even to California, if there was a wire extended;" to Wisler, that "he could attach a wire to it and talk for ten miles, as far as he could have a circuit around;" to H. F. Drawbaugh, that "he could talk across the continent;" to Free, that "the talking machine could be used to talk at a long distance, from Philadelphia to California;" to Landis, that "it could be used a thousand miles; it would take the place of the telegraph;" to Lenig, that "he could talk hundreds of miles through that;" to Updegraff, that "instead of using the old mode of telegraphing he could talk directly through the wire; he thought he could talk as far as you could use the ordinary telegraph wire;" to Draper, that "he thought it was or would be one of the greatest inventions of the age, and would take the place of telegraphing;" to A. Evans, that "he could take this machine and talk clear out to Europe across the ocean;" to Eicholz, that "if he could only get some one to help him once he would run it to Harrisburg, and convince them, and then he would run it from Harrisburg to Philadelphia." He stated to the witness Shank that "it works by electricity;" to Smith, that "it was by electricity;" to Nichols, that "the sound was conducted by electricity;" to C. Eberly, that "the instruments were to convey sound by electricity;" to Coudry, that "they were operated by electricity;" to Shoop, that "it operated by a battery;" to Shireman, that "they operated by magnetism;" to Hawn, that "they would be operated on by a battery;" to N. W. Kahney, that "the machine was operated by electricity by a battery;" to Zimmerman, that "it was electricity that would pass it over the wires; that it would carry the sound right along;" to Hale, that "it was driven by a magnet;" to H. K. Drawbaugh, that "the sound could be carried to a distance on a wire by the use of electricity;" to Lenif, that "electricity was used in connection with it;" to Professor Heiges, that "in connection with a talking machine both magnetism and electricity were applied;" to Goodyear, that "his talking machine was also done by electricity over wires;" to Woods, that "it was to be an electric machine used in place of telegraphing;" to Young, that "it was an electric talking machine which he had invented."

Thus Drawbaugh is corroborated by a cloud of witnesses whose testimony tends to substantiate his narrative. Without stopping at this point to consider the credibility and probative force of their testimony, it suffices to state that, although some of the witnesses seem to have been reckless and unscrupulous in their statements, the great body of them are undoubtedly honest witnesses. It is impossible, however, to believe that Drawbaugh can be mistaken in the substance of his testimony, and the conclusion cannot be ignored that either his testimony is true in its essential parts, or his narrative has been manufactured to fit the exigencies of the case. In order to ascertain what effect is to be given to the corroborative proofs it is important to determine whether Drawbaugh is an honest witness or whether he has intentionally falsified collateral facts, and is therefore to be deemed discredited.

If the defence is to be believed, he had been experimenting with his talking machine from 1866, and had successfully transmitted speech as early as 1870, if not before that time. He testifies that he had used Exhibits B and F in transmitting speech for two or three years before he made Exhibit C. According to the theory of the defendants, Exhibit C was made in 1869 or 1870. At that time he had reached a secondary stage in the development of his invention, and certainly as early as in 1872, when Exhibit C had received its latest modifications, the invention had passed out of the period of rudimental forms, embodying principle merely, into a form embodying nice details of construction, and had reached a perfection not reached by Bell in his earlier patent. Drawbaugh was well aware of the merit and of the great pecuniary value of the invention; he had obtained patents for several inventions of minor value, yet from 1870 until July, 1880, he did not apply for a patent for the telephone. It was of the first importance to explain the reason of his inaction, because it seems incredible that the inventor of the telephone should not only omit to patent it as soon as he could, but should also remain silent for years after others were winning the fame and profits of the invention. Only one explanation was possible, and that has been attempted. As stated in the answer and in his testimony, it is that he was unable to do so by reason of his poverty. The answer alleges "that for more than ten years prior to 1880 he was miserably poor and utterly unable to patent his invention or caveat it." He was asked the question: "Do you mean to have it understood from your last answer that there was any other reason for some period prior to 1870, except your poverty, whether greater or less, which prevented you from patenting your invention, or filing a caveat for it?" His answer was: "If I understand that right, there was no other reason that I can think of now." He proceeds to state that Exhibits F and B exhibited the principle perfectly enough to patent. In the elaborate efforts of the defendants to substantiate the theory of Drawbaugh's inability from poverty to patent his invention, much testimony has been produced to show, and which does show, that he was always more or less in debt, often a borrower of small sums of money, was dilatory in paying his debts and used to plead his inability when dunned, and was often sued and judgment and executions were obtained against him. But it is clear from a few plain facts that the theory of extreme poverty is unfounded, and that Drawbaugh is dishonest in putting it forward. In 1867 and 1869, besides what he received for his wages, he received 5,000dols. from the Pump Company for his faucet invention, besides 1,000dols. in the stock of the concern. On the 1st day of April, 1869, he received 1,000dols. from one Gardner for the sale of a half interest in a faucet invention. He invested 2,000dols. of the 5,000dols. in real estate, lost 400dols of it in an apple speculation, and used the 1,000dols. received from Gardner to buy a house and lot for his father. Between 1867 and 1873 he paid 1,200dols. to the Drawbaugh Manufacturing Company for assessments on his stock, besides 870dols. in labour; and in July, 1873, received from that company 425dols. cash in settlement of its affairs. From 1867 to April, 1872, he was the owner of real estate for which he had paid 2,300dols. in the fall of 1867, and upon which he expended in improvements in the spring of 1868 from 300dols. to 400dols., and which was encumbered only by a prior lien for 300dols. In the spring of 1872 he encumbered it for 1,000dols., not as a principal but as a surety. He was in receipt of 110dols. annually, as rent for a part of this property, occupying the rest himself, until he sold it in 1876 and bought another house in the town of Mechanicsville. He was always in receipt of fair wages for his labour. From April 1, 1875, to April 1, 1876, he received nearly 450dols. for wages from the Axle Company, irrespective of his earnings from other sources, and declined steady work at times because he could make more by job work. Thus it appears that, although it was not convenient at times for him to pay his debts, or he was careless or indifferent, he had not only the means of raising money during all this period, but that on many occasions he had means for investment and for speculation. The pretence that he could not raise the fees to caveat or patent his invention is transparently absurd.

He was accustomed to prepare specifications of patents, and was a maker of models, and advertised himself as an inventor, designer, and solicitor of patents. During the time he was experimenting on his talking machine, and before he applied for a patent, he found time and materials for experimenting with and making the Gifford injector for steam engines, the autograph telegraph, the magneto-dial telegraph, the magneto key, the automatic fire-alarm and the electric clock. During this period he was a friend of Mr. Weaver, a patent solicitor, who frequently gave him advice and professional assistance in return for mechanical services rendered by Drawbaugh, and who drew specifications for him for a measuring faucet and for the magnetic clock. If he was not competent himself to make an application for the patent, it cannot be doubted that with the assistance of Weaver he could have made a proper application at a trifling outlay, if any, beyond the fees of the office.

Drawbaugh devoted a good deal of time between 1867 and 1878 to the invention and construction of his electric clock, and the time and money expended by him in experimenting and constructing this clock in its various forms, especially those made in 1877, 1878, was much more than would have enabled him to patent his talking machine. These clocks were built by him with his own tools and out of his own money, and to build them economically he made a gear cutting machine, which must have cost him more than it would to patent his telephone. In April 1878, he received 500dols. from the Electric Clock Company for the privilege of using his clock invention.

In order to fortify the theory of Drawbaugh's inability from poverty to patent his invention, the defendants have attempted by testimony from him and from others to show that he was extremely solicitous to patent it, and tried to induce others to furnish the means. Mr. Springer testifies that "his (Drawbaugh's) whole mind appeared to be on his talking machine; he told me that many a night he didn't sleep just studying how to improve it." After May, 1872, according to the testimony of Jacob Hawn, the talking machine superseded the clock in Drawbaugh's interest. According to Mr. Holsinger, from 1873 to 1876, "he appeared to be crazy on it. I often tried to get information from him on other subjects, and about half minute's talk would turn him right on the talking machine." Henry F. Drawbaugh, his brother, testifies, "Every time I was down there, from the summer of 1872 to 1879 or 1880, he was working at it and talking, and wanted me to go in with him and furnish means." Mr. Bates says he was in Drawbaugh's shop eight or ten times between the summer of 1874 and the fall of 1877, and "his general conversation was about the talking machine; said he would like to get it patented but had not the means, and could make a fortune out of it." Drawbaugh testifies as follows: "Question. A good many witnesses have testified that you were at various times talking of patenting your electric speaking telephone invention; what is your recollection about that, did you intend to patent it or not? Answer. Yes, sir, I intended to patent it. I had spoken to a number of persons to assist me. I would state to them that I would give them an interest in the invention for them to furnish the money to have it patented. Question. Why did you not patent it with your own money? Answer. I did not have any money. Question. At how early a time did you have the intention of patenting it? Answer. I could hardly say how early. I spoke to persons even at an early time. I spoke to Christian Eberly; it may have been prior to 1870 I spoke to Frank Lee; I spoke to them about taking an interest. They were among the earliest. I can't remember all the persons, as I had spoken to a great many." Lee is not a witness, having died in 1872. Christian Eberly locates the time as between 1867 and 1870. He had been a partner with Drawbaugh in a number of inventions and was a capitalist. He was asked: "When Mr. Drawbaugh showed you his talking machine, state whether he proposed to you to go into partnership with him and furnish the money for that also as you had before that time on the other inventions?" He answered: "Not altogether; he intimated that he would take me in. I don't recollect as

Digitized by Google

I said anything, or what I said." The witness was often in Drawbaugh's shop subsequently, in 1871, 1872, and 1873, but mentions no other propositions. The only other persons Drawbaugh specifies as having been applied to by him are Capt. Moore, Henry Bayler, and Simon Oyster. Oyster was not called as a witness. Capt. Moore was examined as a witness for the defendants, and his testimony is significant. He was the principal of the Soldiers' Orphan School, an institution in the vicinity of Eberly's Mills, and was the secretary and treasurer of the Axle Company, a concern that in part occupied Drawbaugh's shop in 1875 and 1876. He testifies that in May, 1875, Drawbaugh showed him a talking machine; said he was unable to patent it himself, and desired witness to "go in with him and get a patent." He states that he told Drawbaugh he didn't want to go into any new inventions, but that it would be a fortune to any person bringing it out if it could be put to practical use. He identifies Exhibit B as the machine shown him at that time by Drawbaugh. Although he and Drawbaugh maintained intimate business relations for a year after that time the subject seems never to have been referred to again. Mr. Moore was an intelligent capitalist. It is strange that Drawbaugh should have shown him Exhibit B, the crude instrument of 1867-1869, if the perfect instruments E and D were in existence; and more strange that the subject was never mentioned again between them if they had any faith in the value of the invention. Mr. Bayler, the other witness, carried on lumbering and a saw-mill from 1873 to 1877 in the vicinity of Milltown, and employed Drawbaugh frequently to repair machinery. He testifies that in June, 1873, Drawbaugh showed him the talking machine, and he said to Drawbaugh, "Why, Dan, that is virtually a talking telegraph," and advised him to take out a patent for it, to which Drawbaugh replied: "If I had the means I would; if you'll advance me the means to procure a patent I'll give you a half interest." The witness continues: "Generally on him meeting me he would urge it, urge me to take an interest by furnishing him the means to take out a patent." He also identifies Exhibits F and B as the instruments shown him by Drawbaugh. But his books show that during all the time from April, 1873, to May, 1876, he owed Drawbaugh more than the fees necessary for producing a patent.

The defendants produce other witnesses to prove that from 1870 to 1879 Drawbaugh was showing his telephone, adverting to his property, and trying to induce somebody to assist him. Mr. Herr may be cited as in illustration. He testified that in 1870 or 1871 Drawbaugh wanted money to get a caveat to secure his invention, and told the witness if he would help him or procure any person to assist him he would give him a half interest. Without adverting further to the testimony on this subject it is sufficient to say, in view of the fact that there never was a time from 1867 to 1880 when Drawbaugh did not have the money to caveat and patent his invention or the means of borrowing it, the only legitimate effect of such testimony is to discredit the whole defence by exciting the suspicion that it is bolstered up by exaggerated and unreliable testimony. It will hereafter be shown that, among the men with whom Drawbaugh maintained business and friendly relations during this period, there were many of intelligence and means. Some of them may have distrusted his judgment and regarded him as a visionary. Some of them may have been indifferent or timid. But it is incredible that, when only a trifling sum was required for a half interest in the invention, none of them could be sufficiently impressed with its merit or financial value to investigate it seriously as a speculation or an investment. He induced persons to invest in faucet inventions and in his magnetic clock; and it cannot be true that he could find no one to entertain the talking machine which, according to the common rumour of the neighbourhood, was to supersede the telegraph, and, in the words of one of the witnesses, "make Drawbaugh one of the richest men in Cumberland Valley." It was very natural that a hard-headed old farmer like William Daer, on being told by Drawbaugh that he had a machine by which he could talk across the Atlantic Ocean, should advise him to "try it first in talking across the Yellow Breeches Creek," but it is beyond comprehension or belief that none of the capitalists or speculators about him could be induced to seriously consider it if it was an operative device.

Where a witness falsifies a fact in respect to which he cannot be presumed liable to mistake, Courts are bound, upon principles of law, morality, and justice, to apply the maxim *Falsus in uno, falsus in omnibus.* The Trinidad, 7 Wheat., 283. Drawbaugh could not be mistaken in asserting that it was his poverty which prevented him from caveating or patenting his invention. He was not led to the assertion inadvertently. Those with whom he is associated in the defence understood fully, and so did he, that the fact that a professional inventor and patentee did not go to the Patent Office to secure an invention like the telephone for ten years after it had been completed and demonstrated was almost conclusive against the theory that he made the invention, and that unless this presumption could be parried no Court would credit his story. The theory of constraining poverty was therefore formulated in the answer, elaborately fortified by witnesses, and testified to by Drawbaugh. It is overthrown by a few plain, indisputable facts, and Drawbaugh's veracity falls with it.

The defence must rest upon the testimony of the witnesses who corroborate Drawbaugh. The case made by these witnesses is sufficiently formidable to overcome the legal presumption of the validity of the complainant's patents. It is met by the complainant with rebutting evidence, direct and circumstantial, showing the intrinsic improbability of the theory that Drawbaugh was the inventor of the telephone, and showing his conduct or declarations inconsistent with any hypothesis that he was more than an unsuccessful experimenter with the invention. Many witnesses have also been produced by the complainant to attack the credibility and reliability of the testimony of the defendants' witnesses. Of necessity the testimony of most of the defendants' witnesses can only be attacked by showing that witnesses are mistaken as to the time when they saw Drawbaugh's talking machine, or as to what they really saw on the occasions they refer to. The way in which the testimony of Uriah P. Nichols is met will illustrate the general tenor of such testimony. Mr. Nichols was one of the most intelligent and trustworthy of the defendants' witnesses, a farmer and machinist, who testified that on the 18th day of January, 1875, he visited Drawbaugh's shop on business, saw two instruments which he identified as Exhibits B and A, and described their mode of operations as stated to him by Drawbaugh at the time; he says he listened at one instrument while a boy spoke into another two hundred feet away, connected by wires, and heard the boy say: "Is it you, father, speaking?" The complainant produces nine witnesses to show that the occasion could not have been prior to February, 1878. The witness fixes the date by a purchase of lime made by him on the visit, and states that he went to Drawbaugh to see an electric clock of which he recently read a description in a newspaper, and soon after the visit told Mr. Maish and others about the telephone he had seen at Drawbaugh's. The complainant proves that the newspaper article was not published until February, 1878; that when the witness told Mr. Maish of the telephone at Drawbaugh's the latter, who was then a member of Congress, remembered the occasion, knew all about Bell's telephone at the time, and had used it in Washington. Mr. Maish states that as Drawbaugh was one of his constituents he would have been deeply impressed by the conversation if he had understood Drawbaugh claimed to be the inventor. Without attempting to particularise the rest of the testimony for the complainant upon the issue, it suffices to say that several other witnesses were introduced to show that the lime was purchased by Nichols in 1878. Much testimony is given by complainant upon collateral issues of a similar character. One of these issues relates to the time when Thomas Draper ordered a hydraulic ram of Drawbaugh. Mr. Draper was an important witness for the defendants. He testified that he went with Mr. Kissinger, a tenant of his, to Drawbaugh's shop in May or the early summer of 1874, for the purpose of ordering of Drawbaugh a hydraulic ram to be used upon the farm Kissinger had leased of him in April, and that he was never at Drawbaugh's on any other occasion. He identified Exhibit C positively, and Exhibit I less positively as the instruments used, and through which he listened while Drawbaugh talked. The complainant proved that the hydraulic ram was not put to use until the fall of 1878, and undertook to locate the date of Draper's visit approximately by that fact. Seventy-five witnesses were introduced by the respective parties upon the collateral issues. These illustrations show how hopeless a task it would be to review the testimony satisfactorily or analyse it minutely. Five hundred witnesses have been examined by the parties upon the main question and the collateral issues, and their testimony is in a printed record of over 6,000 pages. If it were practicable to do so it would not be profitable, because a microscopic view of the controversy would be inadequate and misleading. In cases where such a chaos of oral testimony exists, it is usually found that the judgment is convinced by a few leading facts and indicia outlined so clearly that they cannot be obscured by prevarication or the aberrations of memory. Such facts and indicia are found here, and they are so persuasive and cogent that the testimony of a myriad of witnesses cannot prevail against them.

NOTES.

THE POSTMASTER-GENERAL.—Mr. Shaw-Lefevre, the new Postmaster-General, has been elevated to a seat in the Cabinet.

LUNDY ISLAND CABLE.—This cable has been interrupted for over three weeks, but at present the fault has not been detected.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 6th February amounted to £3,542.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 6th February were £2,823, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

CURRENTS AND CURRANTS.—*Il Giorno* says that a noted pastrycook of Milan obtains, with an apparatus of his own invention and "a discrete electric current," results which satisfy not only the taste, but also the eyes of his numerous customers.

SS. "ELECTRA."—In describing the system of ventilation applied to the ss. "Electra," p. 261 of last issue, the holes cut through decks in all cabins should read 6in. by 4in., being same size as those in ss. "Volta," and ss. "Magneta," instead of 16in. by 4in.

THE WAR OFFICE AND THE EASTERN TELEGRAPH COMPANY.—A special telegraph wire has been laid on to the War Office from the Eastern Telegraph Company's office in the City, so that not a moment's delay will take place in the receipt of telegrams from the front.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 31st Jan. are £2,684, as compared with £2,865 in the corresponding period of 1884. The October receipts, estimated at £4,147, realised £4,231.

MAXIM-WESTON ELECTRIC COMPANY.—A notice has been given that this company, after making up the deficit in profit and loss account of £2,544 14s. 7d. for last year, has just declared a dividend at the rate of 5 per cent. for the last four months, carrying forward £764 5s. 3½d.

ELECTRICAL LECTURES.—Professor Ryan, of Nottingham University, delivered the second of a course of lectures on "Electricity" in the Town Hall, Ilkeston, on Thursday evening, Feb. 5. These lectures are in connection with the University Extension scheme, and are well attended.

TELEGRAMS FOR THE WEST INDIES.—The cables between St. Kitts and Antigua, and between St. Vincent and Grenada are interrupted; there is, therefore, at present no telegraphic communication with the islands of Antigua, Guadeloupe, Dominica, Martinique, St. Lucia, St. Vincent, and Barbadoes.

GREAT NORTHERN TELEGRAPH COMPANY.—This company notifies that a telegraph station has been opened at Pakhoi in China. The traffic receipts of this company for January, 1885, amounted to £20,800, against £19,360 and £18,400 respectively, in the corresponding months of 1884 and 1883.

TEMPORARY LIGHTING AT BARCELONA.—The most important electric light installation in Spain, though of a temporary nature and put down in a few days, is said to have been that of fifty-two Gramme lamps between the Plaza de Cataluna and the Rambla de Santa Monica, Barcelona, on the occasion of the recent festivities.

ELECTRICAL TRAMCAR AT WANDSWORTH.—The General Purposes Committee of the Wandsworth Board of Works has arranged with Messrs. Siemens Brothers for an electrical engineer to attend and advise the committee during its inspection of the electric car proposed to be used on the tramway lines in Battersea.

THE BELL PATENT IN CANADA.—On 24th January the Canadian Minister of Agriculture and Commissioner of Patents gave his decision, *in re* the Toronto Telephone Company *v.* the Bell Telephone Company of Canada, declaring null and void the Patent No. 7,789, granted on 22nd August, 1877, to Alexander Graham Bell.

ANGLO-AMERICAN TELEGRAPH COMPANY.—We are informed that, with reference to the resolution proposed by Mr. Abbott, Mr. Cyrus Field telegraphed to the company on the 7th Feb., 1885, as follows:—"I am not now and never have been interested to the extent of a single pound in any rival scheme to the Anglo-American Telegraph Company."

COST OF TRANSATLANTIC TELEGRAPHY.—The sums paid for transatlantic telegraphy during 1884 amounted in the aggregate to £888,000, while for the preceding year the amount was £939,000, at the same rate, the reduction being due to depressed trade. Although indications are not wanting of reviving trade, the tariff is somewhat lower.

ELECTRICAL EXHIBITION AT BRUSSELS.—It is intended to hold at Brussels this year an exhibition of electric apparatus chiefly for lighting, and also gas appliances. The difficulty appears to find a suitable building; but the organising committee hope to have the Palais du Midi (intended for the industrial school) placed at its disposal, owing to an arrangement between the State and the Municipality.

ELECTRICAL WORKING OF LEVEL CROSSING GATES.—A scheme for opening and shutting level crossing gates by electricity is being tested in France. A catch, governed by an electro-magnet, secures the gates; and the train, on approaching, closes the electric circuit and releases the catch, when the gates open. The train having passed, the circuit is broken, the gates are shut, and they are secured again by the catch.

ELECTRIC LIGHT IN ITALY.—At the town of Terni, in North Italy, celebrated for its waterfall, the theatre has been electrically illuminated by Calandri, Viglino, and Bizzoni, who are about to lay down plant for lighting the Terni Club and some of the principal shops, distant a kilometre (0·62 mile) from the generating machine. A description of the electric lighting operations at Terni will be found in our issue of July 26, 1884.

INFLUENCE OF PETROLEUM CANS ON THE COMPASS.—It is asserted that refined petroleum in tin cases exerts an influence on the compasses of a vessel equal to the same quantity of iron or steel. The masters of the German ship "J. Weisselholm" and the schooner "Maggie Dalling" have sent in reports confirming the above statement; and in the latter case the captain asserts that his vessel went ashore through an error caused by cased petroleum.

THE TELEPHONE IN PARIS.—In accordance with an arrangement between the French Ministry of Telegraphs and the Société Générale des Telephones, the tariff for conversation between two different towns is fixed at 1f. (10d.) for distances under 100 kilometres; and this is to be reduced one half when two towns in telephonic communication shall have been classed by Ministerial decision as forming part of the same telephonic group.

OVERHEAD WIRES AT WANDSWORTH.—The General Purposes Committee of the Wandsworth Board of Works, having

Digitized by Google

considered the report of the surveyor for Streatham as to telegraph wires having been erected by the London, Brighton, and South Coast Railway Company over Streatham High Road, at Streatham Station, recommended that the company be called upon to remove the wires in question forthwith; and this recommendation was adopted.

UNION ELECTRIC LIGHT AND POWER COMPANY.—The affairs of the Union Electric Light and Power Company being now fully wound up, the liquidators have given notice that a general meeting of the company will be held at the late registered office of the company, St. Stephen's-chambers, Telegraph-street, E.C., on Monday, 23rd inst., at 2 p.m., when an account will be submitted, showing how the winding-up has been conducted and the company's property disposed of.

ELECTRIC LIGHTING AT THE SOCIETY OF ARTS.—We mentioned some time back that accumulators were being tried at the above institution in connection with the existing electric lighting. These were put in as regulators; but on more than one occasion they have supplied the current for all the lamps in the lecture room throughout the evening. The result has been considered by the council so satisfactory that the Storage Company has received an order to fix permanently a set of cells of their latest type.

ELECTRIC LIGHT AT BOSTON.—It appears from the annual report of the Superintendent of Lamps for the city of Boston (U.S.A.) for the past year, dealing with the three systems of illumination—gas, oil, and electricity—employed, that there were 401 electric lamps in use last year, costing the city 65 cents per lamp per night, or 237 dols. 25 cents. per annum. The total cost of these lamps (the greater portion of which are Brush) was 95,137 dols. 25 cents.

LIGHTING FOR BROOKLYN.—The following proposals for lighting the streets of Brooklyn, U.S.A., have been submitted:—From the Municipal Electric Light Company, lights for various streets, 255·50dols. per annum for each standard arc electric light furnished; from the Brooklyn Electric Light Company, for furnishing electric lights in various streets of the Western District, 255·50dols. per lamp per annum, lamps to be erected within the territory covered by the company's wires.

TELEPHONE AT THE CLUBS.—The members of the Sheffield Club have had before them a proposition for introducing the telephone; but only four out of about fifty members voted for the motion, which was accordingly lost. The directors of the Sheffield Athenæum have had a memorial, signed by over sixty members, presented to them, asking for the telephone to be extended to that institution, and a sub-committee having reported favourably, the telephone may be tried for a year to ascertain how far it is appreciated by the members.

PRESENTATION.—Mr. John D. Miller, local manager of the National Telephone Company, has been presented by the subscribers to the Aberdeen Exchange with an illuminated address in token of their appreciation of the services rendered by him as manager to the company at Aberdeen. Reference is made in the address to Mr. Miller's careful management, and the ability, tact, and courtesy which he manifested in commencing his duties under considerable difficulties, and in carrying them to a successful issue. Notice is also taken of the degree of S.T.E. and E. obtained by Mr. Miller in recognition of his engineering skill.

ELECTRO DEPOSIT OF NICKEL ON ZINC.—In coating zinc with nickel, by means of a galvanic current, the zinc must first be cleaned by diluted hydrochloric acid and thoroughly washed. It is then hung in the nickel bath for a short time, taken out, rinsed, and thoroughly scraped, so as to remove all the metal that does not adhere firmly. This operation is repeated till the zinc is covered with a thin film of nickel, which can afterwards be made as thick as required. The suitable current strength is easily found; and when the zinc is once thoroughly covered, the current may be increased without any risk of the nickel peeling off.

PRESERVING TELEGRAPH POSTS.—A correspondent to the *Timber Trades Journal* says that, to prevent the decay of posts at the level of the ground they should be protected, say 6in. above and 6in. below this point, with sheet zinc closely nailed round; and another good plan is to shoe the posts with wood, allowing the shoe to come 6in. or so above the ground. This offers a larger volume of wood to the action of disintegration at the ground level, and gives the post an extended lease of durability. Though the ordinary charring and tarring are no mean preservatives, it is a popular error to apply these remedies to other points than those of the ground level.

THERMO ELECTRICITY.—Professor Riatti has constructed a thermo-electric cell, based upon the principle that the production of electricity is due to the difference of the temperature of two parts of a single fluid. The cell consists of a receptacle of wood or porcelain, traversed by two tubes of copper, with wires at a certain distance between them. By the principal tube a jet of steam is passed, and by the other cold water. The outer jar contains a solution of sulphate of copper. When the circuit is made, the copper of one of the tubes is dissolved, and is deposited in the other. This cell is said to be constant, and not liable to polarisation.

THE TELEPHONE BETWEEN PERTH AND DUNDEE.—A new telephone wire between Dundee and Perth was inaugurated at the central office of the National Telephone Company on the 9th inst. The wire is about 22 miles long, and, with the exception of the wires between Glasgow and Edinburgh and Glasgow and Greenock, is the longest distance to which a National Company's wire extends. The wire to Perth is the first instalment of a projected wire to Glasgow, and probably to Edinburgh. A trunk wire to Arbroath is almost completed, and from thence another is to be carried to Brechin and Montrose, and then on to Aberdeen.

ELECTROLYTICAL SEPARATION OF METALS.—Mr. B. Moebius, of Chihuahua, Mexico, has invented apparatus for refining silver and separating it from gold, platinum, copper, lead, and other metals by means of the electric current. The elements forming the anodes and cathodes of the battery have brushes for preventing the accumulation of metals or peroxides, and oxygen or hydrogen bubbles. The exciting liquid, contained in a water-tight tank, consists of a nitrate of silver solution, acidulated with nitric acid to which nitrate of copper is added. The liquid is heated for diminishing the internal resistance and favouring decomposition of the anode.

ACCIDENT TO ONE OF CROMPTON'S MEN.—The annual dinner of the *employés* at the Chelmsford Electric Light Works, which was held on Saturday evening at the Corn Exchange, Chelmsford, was followed by a shocking accident. About an hour after the company had dispersed the hall-keeper went into the cellar for the purpose of turning off the gas, when he found a man named Edwards, who was employed at the Electric Works, lying at the bottom of the steps quite dead, his skull having been fractured. The door at the head of the steps being open, it is supposed that the unfortunate man stumbled against it and fell head foremost to the bottom.

NOVEL LIGHTNING CONDUCTOR.—The apex of the Washington monument, 500ft. high, and now approaching completion, is protected against the lightning shock by a large conical

Digitized by Google

block of aluminum, to the bottom part of which will be attached a large copper bolt or cord, divided into four parts, one led to each of the four heavy columns supporting the elevator. These in turn will be connected with the well near the base of the monument, thus making a complete and ample connection between its summit and the earth. A similar connection between the temporary top of the column and the earth has always been maintained, thus protecting the workmen as well as the structure itself from the effects of any electrical disturbances.

THE TELEGRAPH BATTALION.—Instructions were received at Aldershot on Monday to hold the air-line section of the Telegraph Battalion Royal Engineers in immediate readiness to embark for Suakim. The section, which numbers about forty non-commissioned officers and men, will be under the command of Lieut. Lindsay. An opinion prevails at the camp that, unless the reserves of this particular arm are called out, very few men will be available, as nearly the whole of this battalion is already in Egypt and at the Cape. Later information states that the reserves to be called out will include a detachment of the 24thMiddlesex Volunteer Telegraph Corps. The air line section of the Telegraph Troop of the Royal Engineers will consist of 40 men, 36 horses, and four telegraph waggons. The wire will extend 50 miles.

SHIP LIGHTING.—The new mail steamer, "Trinidad," lying in Hendon Dock, on the Wear, has been fitted by the Edison-Swan United Electrical Company with 150 20-candle incandescent lamps, distributed throughout the vessel. The globes in the saloon are of frosted glass, and each lamp has a switch for turning the light on or off. There are two large deck or cargo lights, intended to be used while the vessel is loading or discharging cargo at night. These two lamps, each equal in power to 400 candles, are composed of eight 50-candle lights each. The current is supplied by an Edison-Hopkinson dynamo, coupled with and worked by a small double engine, supplied by Tangye Brothers, Birmingham. The "Trinidad" is the third mail steamer which has been thus fitted with the electric light in the Wear during the last few months, and also the second steamer fitted by the Edison-Swan Company, the other being the "Funchal."

QUEENSLAND.—We have received a neat and elegant New Year's card from the officers of the Post and Telegraph Department, Queensland, which, besides pleasure, gives information. The telegraph statistics show that in 1860 the revenue was £938; and in 1883, £70,583. The expenditure in the same years was respectively £1,652 and £76,369, while the officers numbered 201 in 1883, against 7 in 1861. The number of messages transmitted in 1861 was 6,189, having a cash value of £938, and value O.H.M.S. of £122. The corresponding figures for 1883 are 1,018,350 messages, cash £68,724, value O.H.M.S. £15,852. In 1860 there were 160 miles of line with 161 miles of wire, which had extended in 1883 to 6,654 miles of line and 10,618 miles of wire. Telephony, unknown in all 1860, established in 1880, is described as having furnished four exchanges and 352 subscribers in 1883. The population of the colony in 1881 was 226,968; and we think the above statistics show the enterprise of the colonists.

CONSTANT ELECTRICAL GAS LIGHTER.—A form of portable electrical gas lighter, in which the spark is produced by the conversion of the mechanical force exerted by the hand upon a button, has been devised by Herr Ullman, who calls it an "everlasting" gas lighter. The external appearance, as described by *La Nature*, resembles that of the battery lighters already in use, the working parts being enclosed within a vulcanite handle, and the spark emanating from metallic points at the end of a suitable rod. The handle contains an inner concentric tube which is caused, by suitable gearing, to rotate rapidly when the button is firmly pressed; and by this rotation a small statical electric machine is constituted, which in due course charges a small fixed induction coil, whereby the spark is caused to appear at the interrupted portion of the circuit. The apparatus therefore works upon the principle of Sir W. Thomson's "replenisher." The operation is much facilitated by the fact that the electrical portion is hermetically enclosed in a suitable case, the enclosure being also kept dry by a small quantity of absorbent material.

HOUSE TO HOUSE DISTRIBUTION OF CURRENT.—A new method, devised by Sgnor Meardi, of distributing high-tension continuous current to private houses is founded on the following principles:—1. Distribution in series of the leads to the apparatus in which the current is utilised, whether lamps, motors, accumulators, baths for electro-deposit, &c. 2. Subdivision of the current intensity among the line conductors in more ratios of various measure; and, consequently, conductors composed of so many elements, each of small section, limited, various and constant capacity, completely insulated and separated from one another. 3. Differential system of counter-tensions, and variable auxiliary resistances, with automatic regulators, capable of being worked by hand in the event of an audible signal being given by a tension indicator attached. 4. Utilisation of the series at will, with slow and progressive graduation of the resistance, when the series is put in and out of circuit, and in measure as the ammeters and audible signals in the laboratory or place of production give warning in sufficient time of the need to modify the tension in the special element of the conductor, so that the intensity always remain constant.

ELECTRIC LIGHT IN THE BATH.—The Turkish bath, lately opened in Savoy-street, Strand, W.C., is electrically lighted throughout by fifty-seven 10 and 20 candle Woodhouse and Rawson incandescent lamps, in fittings by Tayler Smith. The light of each separate lamp may be switched on and off at pleasure; and most of the brackets may be taken down and put up elsewhere, contact being made with metal shields permanently fixed in the walls. Some of the lamps are enclosed in frosted, and others in crystallised globes, while those in the hot rooms form the centre of yellow lilies pendant from the ceiling. The current is supplied by a 60-light Elwell-Parker dynamo, with an 8in. armature, driven at about 1,200 revolutions a minute by a 4-horse Clark horizontal gas engine. The dynamo is sufficient to generate all the current required; but there are also twenty-six 1-horse Elwell-Parker accumulators, each giving out 2·15 volts, which are charged in the morning, so as to afford a reserve in the event of a break-down. The current is sent through the accumulators, which thus act as regulators, securing a remarkably steady light. J. Wells is the electrician in charge.

ELECTRICAL FIRE ALARM.—The fire alarm, devised by M. E. Raikem, which has been favourably reported upon by the Belgian Commission des Procédés Nouveaux, and by the Director-Général des Postes et Télégraphes in the name of the Belgian Minister of Public Works, depends on the principle of air expanding when heated. A chamber made of brass has a porous bottom for permitting the air therein to slowly acquire the same density as that outside. A glass tube, bent to the form of the letter U and containing mercury, is put in communication with the air chamber, and contains a

Digitized by Google

platinum wire reaching to the bottom and connected with one of the poles of a battery. A rod, terminating in a platinum wire, the end of which is normally a short distance from the mercury, is inserted in the open arm of the tube and connected with a bell. The mercury remains at the same level in both arms of the tube so long as the temperature remains unchanged, or the increase is so slow that the porosity of the bottom permits the air in the chamber to acquire the temperature of the outer air; but, when the heat is suddenly increased, the air in the chamber expands, depresses the mercury in one arm of the tube, causes it to rise in the other, and, by making electrical contact, rings the bell.

GAMBLING AND BETTING IN THE POST OFFICE.—The Postmaster-General has just issued an official instruction upon gambling and betting, in which he says:—"A case having recently occurred in which betting on horses and playing with cards for stakes far beyond what the players could afford to lose was proved to have taken place, not only on the official premises, but in some instances during the official hours, the Postmaster-General has felt constrained to direct that the superior officer who had taken part in and encouraged these malpractices should be dismissed, and that of six subordinates one should be required to resign and five be reduced in their class, the reduction ranging from four to forty-four steps. A postman also who acted as housekeeper has been deprived of the housekeepership, as well as his good conduct stripe. The Postmaster-General deems it his duty to make these punishments known by way of warning, as in the case of Post Office servants he regards gambling in any form as a most serious offence, and one which it is incumbent on him to put down in an exemplary manner." The Postmaster-General also re-issues a notice concerning betting which appeared in the Post Office Circular of the 26th of August, 1878, as follows:—"Any servant of the Department who shall hereafter be concerned in betting will render himself liable to dismissal."

AN EARLY PIPE-LIGHTER.—It is interesting to compare the following description of a contrivance for producing fire for lighting candles, pipes, &c., with the handy little apparatus provided at the present day by Trouvé and others for the same purposes. The description is from a patent taken out by Mr. Richard Laventz, of Hammersmith, in February, 1807. The apparatus was so contrived that on raising a button an electric spark was produced, which ignited a stream of hydrogen. The gas was produced from a mixture of zinc and muriatic acid in one vessel, ascending by a pipe into another vessel previously filled with water, and forcing the water thence into another and higher vessel which, in proportion as the water rose, pressed by its statical weight, so that when the cock of a pipe was opened allowing it to pass outwards in a small jet with considerable velocity. The electric spark was produced by an electrophone previously excited, which was so connected with the cock above mentioned that the same motion which turned the latter raised the resinous plate of the former from its metallic plate. The spark thus caused passed from one metal knob to another across the hydrogen as it issued, and inflamed it. The knobs were joined to the electrophone by wires. Lastly, a candle was so fixed that the jet of hydrogen must strike its wick. The whole apparatus was included in one portable box of tin or other material. This was before primary batteries and platinum wire were as common as they are now. The metal platinum had, indeed, only been discovered some 60 or 70 years before. The electrophorus was not so old as that, and the primary battery quite in its infancy.

ELECTRIC FISH.—In a magazine published in 1807 it is stated that "Adanson first discovered that the benumbing faculty of certain fishes depends upon electricity. He made his experiments upon the *silurus tremulus*. It is also affirmed that he was the author of the letter on the electricity of the tourmalin, which bears the name of the Duke of Noya Caraffa." This letter was written in 1758; and Adanson is said to have assured the writer of his biography that he was really the author, though it was published in the name of the duke, a Neapolitan nobleman. It was addressed to M. Buffon. Adanson appears to have been a genius of no common order, and made himself famous by his researches in natural history. Born in 1727, at Aix, in Provence, we are told that so early "as the age of five he began to make observations on the smallest plants, such as mosses, which he cultivated in the window, and upon the minutest insects." In 1748 he went to Senegal, where he remained for several years ardently pursuing his favourite study. In 1750 he was elected corresponding member of the French Academy of Science, and in 1759 a member of that body. Our own Royal Society elected him an associate in 1760. He had many tempting offers of lucrative professorships, but he declined all, preferring to live in positive penury, in order to confine his whole attention to botany and natural history. He died on the 3rd August, 1806, in his eightieth year. His lodging at this period was "a ground floor, without cellars, in one of the lowest streets in Paris." He appears to have been descended from a Scotch family which had followed the fortunes of James II.; and his biographer hazards the guess that his proper name was Adamson. An account of his travels and discoveries in Senegal was published in 1757, and afterwards translated into English. Although we are not told so in the memoir from which we have taken the above facts, it is more than probable that this work contained some account of his discovery of the electrical properties of certain fish.

TELEPHONIC CONNECTION OF COASTGUARD STATIONS.—On 9th inst. the Docks and Pilotage Committee of the Aberdeen Harbour Board had before it a letter from the assistant secretary of the Board of Trade, dated 18th October last, with reference to the Board's contribution towards the expense of maintaining telephonic connection between Aberdeen and the coastguard stations at Cove and Donmouth, reminding the Commissioners that the contributions which the Board of Trade guaranteed had now been paid; that whether they would make any further contributions would depend upon circumstances, and have to be considered when the proper time arrives; and requesting that the Department might be furnished with a report showing to what extent the telephone had been of service in connection with vessels in distress. The committee resolved to recommend that a reply should be returned to the Board of Trade to the effect that the telephone has been of great service, and expressing the Commissioners' hope that the Board of Trade will continue the contribution. The committee at the same time instructed the convener, the shoremaster, and the captain pilot, to prepare a report for transmission to the Board of Trade, showing to what extent the telephone has proved of service in connection with vessels in distress. The clerk read a report from the captain pilot to the effect that on several occasions the telephone had been found of great service in notifying the fact that vessels in distress were being driven towards Aberdeen. By receiving notice through the telephone regarding ships in danger, tugs were got ready, and assistance rendered, which resulted in the saving of life and property. Shoremaster Mearns moved the approval of the minute and that the report be sent to the

Digitized by Google

Board of Trade. The motion was agreed to; but Baillie Paterson gave notice of a motion in accordance with his remarks, that the telephone being used for commercial purposes as well as for inquiries as to ships in danger or distress, those who used the wire should pay for the privilege, while probably the stamps that had been recently issued by the Telephone Company might be called into requisition.

Electricity in Cotton Mills.—The *Textile Record*, in an article on this subject, says that one of the most formidable foes to be contended with in cotton mills is electricity, which is generated with fearful rapidity, in dry, frosty weather, in all parts of the mill, by the friction of machinery and belting. The writer has frequently, on windy days, removed the conducting wires from the counter and frame driving belts and held "slivers of roving," 42in. long and weighing about 3 grains, opposite a 2in. belt, in which there was sufficient electricity to hold the sliver firmly in a horizontal position. On admitting the sun's rays near the belt, he saw streams of fibre flying in the air and loading the belts with cotton. To ascertain the injury done to the yarn, he selected a place where the electrical force had been subdued by good insulated copper wire conductors, and then tested yarn from ten spindles on the end of a spinning frame nearest the driving belt. Without quoting the experimenter's figures, it is sufficient to say that he found 59 to 65 per cent. of moisture in the air, with a depreciation of nearly 3 per cent. in the quality of the yarn due to the action of electricity; and when there was but 53 per cent. of moisture in the air, and the electricity therefore much more powerful, he found over 4 per cent. difference in quality. By mounting a good magnifying glass over the rollers at the end of the spinning frame, near the belts, the fibres were seen distinctly. On throwing rays of sunlight between the rollers with a good hand mirror, not only were the fibres seen drawn out at right angles from the surface of the sliver as it passed from the bobbin to the rollers; but the fibres between the rollers were seen constantly swinging off at every conceivable angle, giving the thread of warp yarn a rough woolly surface. He insists on the importance of placing all drawing, roving, and warp spinning machinery in the most favourable positions, away from the influences of electricity, the conditions of which are constantly varying, and of providing insulated wires to convey the currents to the ground, care being taken to have an unbroken connection of metal, so that the current shall not be severed.

General Gordon at Aden.—Now that, as a nation, we are mourning the probable death of a simple-hearted soldier, and of one of the greatest of the world's modern heroes, we feel a melancholy satisfaction at being able to contribute our mite to the fund of information respecting him. It has been our good fortune to have met General Gordon, at intervals of years, in several different parts of the world; and it will be fresh in the minds of at all events a few of our readers that he, on the occasion of his proposed voyage to India with Lord Ripon in 1881, honoured the station of the Eastern Telegraph Company, at Aden, by a visit. The eccentricity which invariably marked his character led him to decline the social attentions which the resident and other important executive officials would have thrust upon him; and it is in keeping with his well-known kindness of heart that he should have accorded those favours to the humble which the great sought after in vain. He came to see us one unusually hot morning, toiling up the ninety-two steps from Aden's only road to the summit of Râs Baradli without a murmur, and, walking quietly to the shadow of the office, sat down on a stone and, removing his hat, entered into conversation with one of the junior local clerks, in whose account of Aden he seemed to be vastly interested. One after another we went out and had a peep at "Chinese" Gordon, whom imagination had invested with manifold terrors, but instead of the dreaded fire-eater, we were astonished to find an amiable and unassuming gentleman, who received us not only with kindness but almost with diffidence. After he had rested, and accepted a glass of water at our hands, we had the pleasure of conducting him through the offices and the testing room, where he seemed desirous of remaining until he had mastered every detail of electrical engineering. Shortly afterwards, he took his leave of us with reiterated thanks, and went to the Artillery mess to lunch. It was proposed to invite him to dinner, and had we done so I think he would have come, but somehow or another the project fell through. General Gordon was to those beneath him an essentially charming man. He imparted confidence to the most diffident, and by a series of judicious questions left one, pumped, it is true, but glowing with satisfaction at having contained so much information.

Report of the Kew Committee.—We glean from the report of the Kew Committee for the year ending 31st October, 1884, that the values of the ordinates of the different photographic curves determined in January were :—

Declination : 1 inch = 0° 22′·04. 1 mm. = 0° 0′·87.
Bifilar, January 4, 1884, for 1 inch $\delta H = 0{\cdot}0276$ foot grain unit.
„ 1 mm. „ $= 0{\cdot}0005$ mm. mgr. unit.
Balance, January 4, 1884, „ 1 inch $\delta V = 0{\cdot}0251$ foot grain unit.
„ 1 mm. „ $= 0{\cdot}0005$ mm. mgr. unit.

The distance between the dots of light upon the cylinders of both the bifilar and vertical force magnetometers having become too small for satisfactory registration, it was found necessary to readjust each instrument, after which the scale values were again determined on January 11th, with the following results :—

Bifilar for 1 inch $\delta H = 0{\cdot}0267$ foot grain unit.
„ 1 mm. „ $= 0{\cdot}0005$ mm. mgr. unit.
Balance „ 1 inch $\delta V = 0{\cdot}0296$ foot grain unit.
„ 1 mm. „ $= 0{\cdot}0005$ mm. mgr. unit.

The difficulty experienced in adapting ordinary unprotected gas burners to the bifilar and balance magnetometers, owing to the extremely sensitive nature of the gelatino-bromide paper, has now been overcome by the use of a small screen of blue glass interposed between the flame and mirror. This diminishes the intensity of the light, so that the traces are now well defined instead of being blurred. Professors Rücker and Thorpe visited the Observatory on July 17, 18, and 19, for the purpose of taking a series of absolute magnetic observations preparatory to surveying the western coast of Scotland, as a preliminary operation towards the proposed repetition of the survey of Great Britain and Ireland. The following clocks are kept carefully rated as time-keepers of the Observatory :—French; Shelton K. O.; Shelton No. 35; and Dent 2011. By the courtesy of Mr. Preece, Superintendent of Telegraphs, the Richmond Chief Post Office was placed in direct communication with the Royal Observatory, Greenwich, on January 22, and enabled to receive the time signal at 10 a.m., when a period of cloudy weather had rendered the true time a little uncertain. Among the experimental work, the sub-committee appointed last year as to the magnetic survey of Great Britain and Ireland has now under consideration the details necessary for the early prosecution of the survey; and during the past summer Professors Rücker and Thorpe made preliminary observations at a number of stations along the West Coast of Scotland, their base observations being made at the Observatory as above stated.

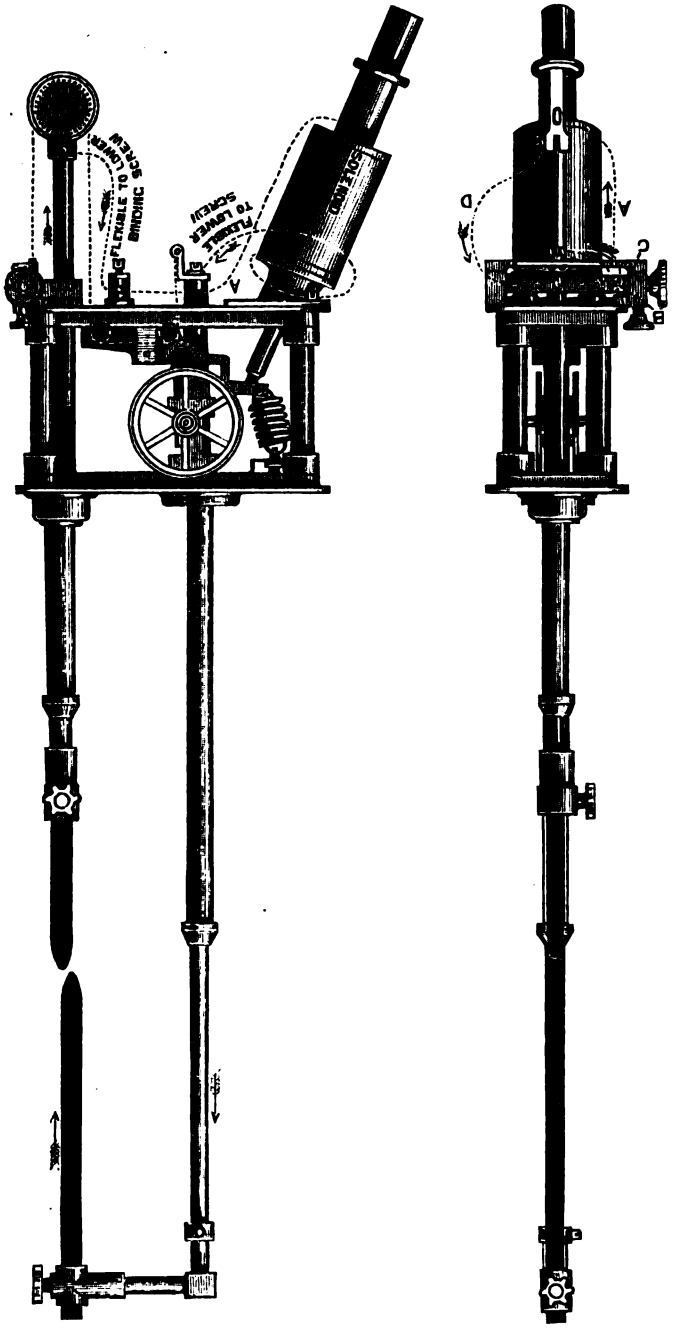
CROMPTON'S SEARCH LAMP.

We illustrate this week what will no doubt be interesting to our readers—namely, a very simple search light, designed and constructed by R. E. Crompton and Co., of Chelmsford. Up to the present time the lamps for search lights have been hand-regulating; but Messrs. Crompton and Co. have perfected a self-regulating differential focussing lamp, which has been satisfactorily tried under varying conditions. The lamp is a modification of the well-known Crompton-Crabb arc



FIGS. 1 AND 2.—The Crompton-Crabb Self-Regulating Differential Focussing Lamp for Holophote.

lamp. It combines not only the usual excellent principles of the D D lamp, but is also provided with a later patent compensating lever, by which arrangement the amount of carbons consumed does not alter nor disturb the equilibrium of the lamps, and a very small movement of the solenoid, or armature core, gives a comparatively great travel to the carbons, and thus makes the lamp very sensitive. To bring the focus of the lamp in the focus of the parabolic mirror, it is adjusted by a milled-headed screw in the vertical, and by a similar screw in the horizontal direction. The whole of the working parts are below the carbons, and enclosed in a light wrought-iron casing, with sliding door on both sides, to give access to the parts of the lamp. The case is fitted to the rolled steel tube, fitted with a strong gun metal casting on both ends. In one end is mounted a 24in. diameter Chance parabolic mirror (this is a decided advantage in cost to the usual

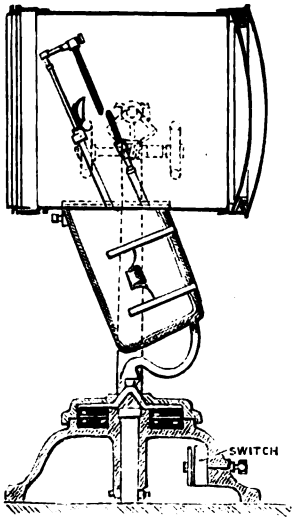


FIG. 3.—Vertical Section.

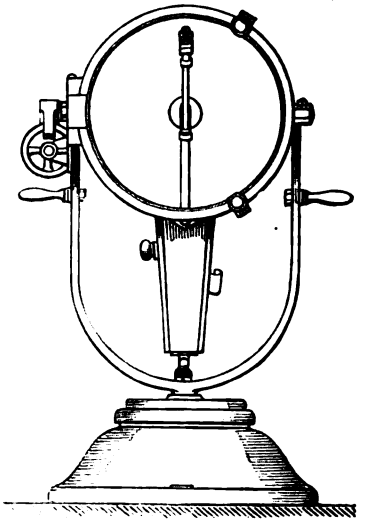

FIG. 4.—End View.

dioptic lenses). The mirror is fastened and held in position with springs at the back, to prevent injuries by concussion due to the firing of heavy guns. At the other end is a strongly-hinged gun-metal door, carrying a thick plate glass front, provided with a neat and simple fastening for opening and closing. The

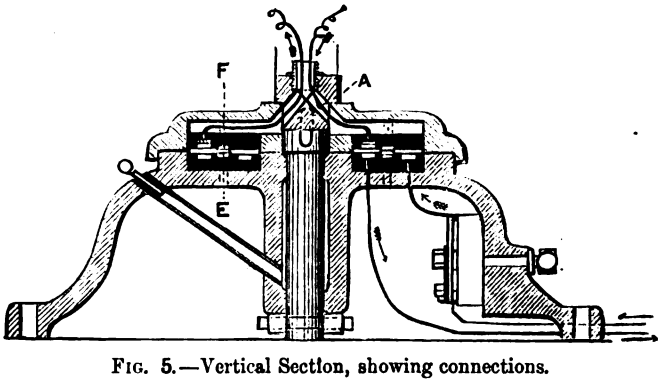

FIG. 5.—Vertical Section, showing connections.

steel cylinder is fitted with gun-metal trunnions, which rest in gun-metal bearings held in a strong wrought-iron fork, which is fixed into a movable cast-iron top and passes through into the lower cast-iron base for turning in the horizontal plane. On one side of the trunnions is fixed a quadrant and worm

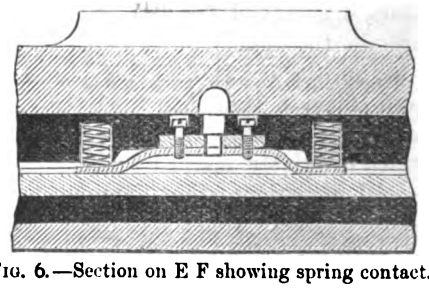

FIG. 6.—Section on E F showing spring contact.

for raising and lowering in the vertical through a certain angle. In the cast-iron base are fixed the contact rings and sliding brushes to supply the current to the lamp in any position. On the outside of the base is also fitted a switch, on either side of which the cable enters, and is connected up as shown.

Digitized by Google

The drawing is so clear as to need no further detailed description; and we venture to say it is very characteristic of the above firm to give to the profession full descriptions of everything they manufacture. We understand that Messrs. Crompton and Co. manufacture search lights fitted with 24in., 20in., and 16in. diameter mirrors. They have at present two in hand of 25,000 candle-power each, for the ironclad "Aquidaban," which is being built for the Imperial Brazilian Government by Messrs. Samuda Brothers. Besides the two arc lamps, the ship is being fitted throughout with incandescent lamps by Messrs. Crompton and Co., the general arrangement of which we hope shortly to be able to place before our readers.

ALTERNATING CURRENTS.—MUTUAL-INDUCTION.

BY THOMAS H. BLAKESLEY, M.A., M. INST. C.E.

(CONTINUED FROM PAGE 259.)

The interesting experiments of Mr. Willoughby Smith on the effects produced by inserting masses, or as they were described screens of metal in the field of two coils on their mutual induction illustrate this proposition. Though the undulations of the primary electromotive force were not in this case harmonic, but were produced by the mere commutation of the poles of a battery, yet there is no doubt that the effects produced in the secondary coils by this mode of generation would approximate to those illustrated here. From the figure it is clear that a large increase in the value of M will greatly diminish the proportion which h bears to e, but unless L′ is largely increased, the increase of M will not largely alter the value of CE, though h be greatly diminshed, and f depends on CE and L′. In the lecture which the writer had the good fortune to hear from Mr. Willoughby Smith the chief omission seemed to be that of a dynamometer in the primary coil. It is highly probable that a great falling off would have been noticed in the reading of such an instrument, when the metal was placed in the field, even when the dynamometer in the secondary circuit showed no falling off of current. The faulty use of the idea of *screening* would have been made very manifest by such an experiment, for it would have seemed as if the screen had been enabled to *maintain* the effect of the *radiation* on the recipient circuit when the source of the radiation itself had become weaker. I have, in fact, illustrated this point in an experiment. A battery and electric tuning fork were joined in circuit with the primary coil of a Ruhmkorf apparatus of which the usual vibrator was constrained in position to maintain contact, the tuning fork taking its place as vibrator. In the scondary circuit was a Bell telephone. The core was removed and the apparatus set to work, both the tuning fork and telephone singing in unison. On pushing the core into its place in the centre of the coils, the intensity of the tone of the telephone was increased, but that of the tuning fork was diminished. The period was $\frac{1}{430}$ of one second, the tuning fork giving the A above tenor C. Probably a lower note would have increased the effect observed. To render the effect on the tuning fork more evident, it is well to silence the telephone. This can be conveniently done by holding it mouth downwards and burning a wisp of paper about 6in. beneath. On the other hand, the figure and the formulæ show that when the period is diminished, other things remaining the same, both the effective electromotive force in the primary and that in the secondary circuit grow smaller compared with the impressed electromotive force. But the equation (γ) indicates that when T is diminished, *i.e.*, when the alternations become more rapid, the relation of the current in the secondary circuit to that in the primary circuit becomes greater; thus, in that part of Mr. Smith's experiments which dealt with an augmentation of the rate of alternation, the energy could hardly be said to be *screened* when a dynamometer in the primary coil would have demonstrated a greater falling off in the current in that circuit than occurs in the secondary circuit. To describe such an effect as due to screening would be as if one suffering from the radiation from a grate should pull between himself and it a screen, which, by being drawn into the middle position, should, by suitable mechanism, cause a bucket of water to be emptied into the fire, and were then to declare that the screen had stopped the radiation by virtue of being a screen.

[The above forms the completion of the chapter on "Mutual Induction," which was unavoidably crowded out of our last issue.]

(TO BE CONTINUED.)

THE LATE DR. DAVY.

It is with extreme regret that we record the death of Dr. Davy, whose name is so well known to our readers from the investigations of Mr. Fahie. In recognition of Dr. Davy's pioneer efforts in electric telegraphy, the Society of Telegraph Engineers had quite recently elected him a honorary member. Dr. Davy had received this information by telegraph but a few days before his death, which took place at Malmesbury, Victoria, on the 28th January. It will be unnecessary for us to give in detail the incidents of Dr. Davy's life, inasmuch as they were given very fully in a biographical sketch in our issue of July 28, 1883. Dr. Davy was born in 1806, and hence, at the time of his death, was seventy-nine years of age. As early as 1836 he appears to have conceived the possibility of an electric telegraph, and seems to have had an excellent knowledge and thorough grasp of the properties of electricity. A full account of his work has been given by Mr. Fahie in our pages, and we only regret that Dr. Davy's claims to recognition were not sooner admitted. In 1839 Dr. Davy went to Australia; he was one of the founders of the Royal Society of Victoria, and an active worker among its members.

CENTRAL STATION LIGHTING.

The following is an abstract of a paper read by Dr. Fleming, based upon his experience in America. The information contained in this paper is on points not of very general knowledge respecting central station lighting, its difficulties, and its successes, with respect more especially to the incandescent lighting in New York. The facilities of Dr. Fleming were exceptionally good, and the results given in this paper are not merely those of a hasty visit, but of weeks of careful scrutiny, and hence may be taken as absolutely accurate. Things that chiefly interest us in the history of all great experiments are the difficulties that have arisen and the methods by which they have been overcome. It has been well said that if Faraday's "Experimental Researches in Electricity" is a valuable book, yet Faraday's experimental failures in electricity would be almost as valuable, and accordingly Dr. Fleming mentioned first some of the difficulties in the problem of distributing large currents for illuminating purposes. He then said:—

When Mr. Edison had completed his lamp and his dynamo, which he had practically done some time before the Paris Exhibition, he knew that between him and the realisation of his project of central station lighting there stood the great difficulty of the underground conductors. He realised that the maintenance of an equal potential over a large conducting network buried in the earth and the necessary insulation of the same were not easy things, but involved stupendous difficulties, which no small scale experiments could overcome; and the history of his mind on this subject is most interesting as gathered from the study of his patents. He recognised that in order to give his station a chance of success he must pitch upon some locality where there was as great a density of consumption of light as possible—that is, as many lights per acre or as much vertical lighting as could be obtained; and he selected a spot in the extremity of Manhattan Island. He was intimately acquainted with the various projects, whose name is legion, for underground conductors, and he recognised most of them as branded on their foreheads with the stamp of impracticability. All such schemes as using the metallic sheath of an insulated conductor for a return were tried and

Digitized by Google

abandoned; cables dragged through metal or stoneware pipes, troughs or channels, or laid in wooden casing, were examined and condemned. He finally selected to use copper rods, segment shaped, and put, together with an insulating material of bitumen and oils, in an iron pipe. These were joined together in 20ft. lengths by copper screw connections, the joints soldered. The reason he did this was because in city streets it is almost impossible to get a clear run free from other pipes in which to lay a conduit. If anyone not familiar with sewer work only looks for five minutes at a street dug up it will be seen that the entanglement of pipes crossing at various levels, and crossing out of the street under the pavement renders it impossible to use any method which cannot easily and cheaply be accommodated to the instant necessity of a change of level in laying down.

The first difficulty met with was in soldering the connections of the 20ft. lengths. The joints had to be electrically perfect, and the getting of a good joint in two highly conducting copper bars, which run away with the heat as fast as you put it in, and the countless difficulties of insulation at the joint brought the workmen sometimes to despair. Edison himself was down on his knees in the trenches night after night until the job was got through, and thirty or thirty-five miles of underground conductors laid. Now came the question of the feeders. As you know the current has to be got into this double network at one side in certain places and got out again at the other, and the question of *how* and *where* to attach the feeders was the next obstacle. Edison at first thought that the problem could be solved mathematically, and so it can by a method due to Maxwell; but the mathematical solution only applies to a given case, whereas, in the real case the points of consumption are continually shifting, and the thing wanted is a practical solution. At last he did the thing experimentally. The probable consumption was first estimated as closely as possible, and the probable localities of lamps represented on a plan, and by experimental methods, the best localities found at which to supply the current. From the central station twenty feeders go out to these points, and at all the street crossings are circular junction boxes, into which the sixteen ends of cable from four sheets come to two copper rings + and −, and the feeders are attached to these. As soon as the station was started, on September 4, 1882, difficulties began. First, it was found that the consumption of light shifts, the centre of gravity of consumption varies, the chief bulk of the lights are going in one place at one time, and at another at the next hour. Hence they require to have a command over the point of supply, and to do this they have had to throw out of use six of the feeders, and only use 14, not always the same 14. What this proves is that plenty of spare feeders are required, so that if the potential is found to be low at one spot it can be brought up, and if high lowered. They would have preferred, if possible, to add spare feeders. This necessitated a little too much load on the feeders, and one day all the main safety catches went, and put the station out for four hours, but this is the only occasion in two years and a half. Next it was found that the conducting network was too rigid, and broke or got damaged by the stresses brought upon it by traffic in the streets. Owing to the varying loads on the surface of streets, and the unequal density of the soil beneath, in some places hard and compact, and in other places where it has been recently opened, spongy, it is essential that the conducting system shall have a power of accommodating itself to small displacements without injury. Gas and water pipes do this by the method of attachment. The first methods of coupling the 20ft. lengths were too rigid. Then, when many mishaps had occurred, Mr. Edison devised a cup and ball joint at the coupling box, which gives a certain play to the skeleton, and gives the necessary elasticity. He told me it was a perfect success. Next as to the insulation. The compound used is really a stiff fluid; and when the pipes containing the two copper rods are bent the flexure in some cases brings stress to bear, which makes the rods gradually change their place in the material and come together. It is this very quality of bitumen being really a fluid that makes it undesirable to lay down cables in bitumen, unless the cables are kept in position by solid insulating bearers or bridges. The result of this was that in some cases they had dead crosses both in mains and in feeders. The methods now adopted are to wind the bare rods spirally with string, then put them together and wind string over the two, then put them in iron pipes and force in the insulating compound when fluid, and thin danger from dead crosses is obviated. There is another cause of cross leakage, viz., conduction through the bituminous compound as the conductors get warm; but of this I will not speak, as I am now engaged in a series of experiments in the conducting power of oil and such like bodies at high temperatures. Lastly, accidents happened from want of mechanical strength. When navvies have to take up streets they are not too choice where they drive their pickaxes, and in many cases they drove them through the iron pipes; but as occasion offers the thin iron gas pipe first used is being exchanged for thicker iron steam piping, and this result prevented. Experience therefore has shown the need for, 1st, elasticity in the network; 2nd, spare feeders; 3rd, great mechanical strength; 4th, highest perfection of insulation in both mains. The insulation of the + and − side is measured every hour, and the exact amount of leakage estimated, and its locality ascertained. This is never allowed to exceed one lamp over the whole system. With regard to future improvements there is room for much. Enough has been said to show you that it has not been easy work to devise a system of underground conductors for large currents of even 100 volts pressure, and it will be more difficult still to devise a system on an equally large scale if the working pressure is higher, since the breaking stress tending to carry electricity through the dielectric varies as the square of the electromotive force.

It is only within the last year that the problem can be said to have been approximately solved, even for incandescent lighting. Experience has also brought forward the necessity for perfectly simple means of getting each street length isolated for testing without digging up streets, and for easy replacement of safety catches at each end. This is now done by the cast iron box, closed by a manhole lid, at each street crossing. Each positive main is joined on to the positive copper ring by a fusible slip, and each negative to the negative ring. Experience has shown the need for the most perfect contacts at these places, since a loose contact that would generate little noticeable heat with a 100 ampere current creates a very different state of things with a 500 ampere current. One thing is certain—viz., that the laying of the two conductors in one tube is a difficulty, and it would be better to have them separate. Dead metallic crosses would then be impossible, as even if both mains are earthed the polarisation resistance is considerable. We may pass next to some criticisms on the chief details of the generating station. What they did was to buy two houses in Pearl-street (something like Thames-street), gut them, put in iron girders and struts, build chimney stacks, and put in Babcock boilers, Porter-Allen engines, and six of Edison's big dynamos, driven direct. They put the boilers downstairs, and the heavy engines and dynamos upstairs, and in this they made a mistake. The vibration is excessive, but it does not matter. On this question of injunction for a nuisance they enjoy special advantages. The elevated railway runs down the street, and nothing can be a greater nuisance than that is. I made special tests on the economy of their boilers and engines, which showed fairly good results but left plenty of room for improvement. The result of investigation into the lamp hours of the lights in this installation showed that the maximum does not reach 1,000 hours per annum. Now, between the engine cylinder and the lamp you have the following losses of energy:—Friction in engine and dynamo; eddy currents in iron of armature and bolts; eddy currents in copper rods of armature; loss in mains and feeders; loss in badly fitting safety catches, lamp sockets, house wiring, switches, &c.; and the result is that of 100 parts of power indicated on the piston, 48 per cent. only gets dissipated in the filament as light and heat. The other 52 per cent. is totally lost, of which more than 40 per cent. will be

Digitized by Google

accounted for outside the mains, and even with the present boilers represents a loss of 1,880 tons of coal a year. Here is a gap for engineer electricians of the future to fill up. There is a more striking fact than this. The horse-power hours of energy dissipated as light and heat in all the filaments of all the 12,600 lamps in six months is 500,000. This is equal to a million million foot-pounds. The coal used in six months is 1,887 tons = 4¼ million pounds nearly. Each pound of coal contains 12,000,000 foot-pounds of energy. Hence nearly 50,000,000,000,000 (*fifty* million million) foot-pounds of energy are used to get *one* million million as light and heat, or 49–50 of the total energy of the coal is irrecoverably lost. The second law of thermo-dynamics forbids our getting back the whole of this, but there is a vast fraction which can be recovered. Can we ever hope to bridge this gulf and get the energy out of the coal direct, and, if so, where is the genius who is going to show us how? The world waits breathless for his advent.

The author thought it would be advantageous to use compound machines. Referring to meters, he said: Meters deserve one word. I do not think, from what I know of the zinc voltameter meter that it is the meter of the future. We are still waiting for an accurate mechanical meter, not dependent on complicated gear, and capable of being made for £3 or £4, or less; so that a rental of 1s. a quarter may pay the interest on capital outlay on meters, and provide a little something for a meter sustentation fund, for pensioning off and replacing old and decayed meters. My determination, of the accurate lamp hours of the station has enabled me to determine the average hours' burning of each lamp per year, and it is about 900 hours. Now, this is very interesting and important. It shows that in a district composed of shops, warehouses, restaurants, banks, &c., when people tap and use the light as they like, the average lamp use per annum is less than 1,000 hours. Now, I do not believe that a residential district would double this, and that therefore all those estimates for cost of electric lighting of towns based on 2,000 hours and upwards are misleading and incorrect. In one estimate, which was drawn up for the town of Sheffield for 10,000 lamps, the draughtsman assumed as the basis of his calculation 30,000,000 lamp hours per annum. At the end, however, he says this is probably too much, and finally surmises that half that amount would be right. Any estimates of cost as compared with gas are in error if they assume much more than about 1,000 hours per lamp per annum.

I must now say one word on the subject of multiple conductors. In July, 1882, a patent was taken out by Dr. Hopkinson, and followed by two others by Mr. Edison in December, 1882, and June, 1883, for a system of multiple conductors, in which combined parallel and series grouping is used for dynamos and lamps. You all know about it, so I need not describe it. Its advantage is that it effects a saving of copper over simple parallel in the proportion of $\frac{M}{2(M-1)^2}$ to unity, when M is the number of conductors. Practically for three conductors it only saves about 30 per cent. on the whole.

They have this system working in thirteen places in America, and in three of them the triple conductors are underground, and in one tube (Newburgh, Brockton, Fall River). I had a long and special talk with Mr. Edison on the extension of this. To my mind one of the most hopeful directions for inventors to work is given—that ground is too expensive in a district to admit of a central station, nevertheless, we can bring in from a distance to a central room current of high potential by light mains, and there split up the potential and distribute it. It can be done by multiple conductors without secondary batteries or secondary generators. The problem of the future is not central stations, but excentric stations, getting electricity generated on cheap land, and bringing it in by highly insulated feeders at high potential to places of division.

One word in conclusion about the Board of Trade model Provisional Order. That has got to be remodelled, like the Act. When I explained to Mr. Edison the delightful intricacies of A and B districts—fines for not keeping the potential constant, choice of lamp left to customer, and so forth, he simply laughed. A model order, if orders there are to be, must be drawn up with the assistance of those who have studied central stations in operation to obtain conditions which are consistent with the actual difficulties which are met with.

Although we in England seem to drag behind, I yet believe that the interesting and fascinating problem of publicly distributed electricity will be solved some day for ourselves on English soil. We call our practical electric units after the names of great investigators. Three out of the eight are named after Englishmen; and it is impossible to doubt that the country of Watt, Faraday, and Joule has in it engineering and electrical skill to overcome the difficulties to which I have most briefly alluded; and, unless there is some radical impracticability about the whole problem to grapple successfully with it, and give us, in the dying words of Goethe, "More Light."

LEGAL.

In the Chancery Division of the High Court of Justice on Monday, 12th January, 1885, Vice-Chancellor Sir James Bacon gave judgment "In the Matter of the Companies Acts 1862 and 1867, and in the Matter of the Mediterranean Extension Telegraph Company, Limited."

The VICE-CHANCELLOR said: I think the difficulty in this case is more apparent than real when the constitution of the company comes to be considered. This was a joint-stock company, formed by contribution from the several shareholders, and there was a power to increase the capital of the company. They resorted to that power, and they did increase the capital by issuing preference shares. They did it, and I suppose they could do it upon no other terms than to raise the dividend up to 8 per cent, and so, while the company was a going concern, that went on. Now, the 88th section, upon which most of the discussion has arisen, seems to me to be perfectly plain. It is this: No dividend shall be payable except out of the profits arising from the business of the company. £7,200 paid by the Government was part of the profits of the company. Then it provides that the profits shall be estimated independently of such sum as the Board may think proper to set aside as a reserve fund to meet contingencies, or for equalising dividends, or for repairing or maintaining the company's telegraphs or works, or for the purchase of, or any expenses connected with, any patent of the kind mentioned. Now, the meaning of that is, when we come to take an account of the profits, which is what we have earned and what we have got, the profits shall be calculated. But, we will reserve money enough in the till to enable us to carry on other business. One thing will be the equalisation of dividends. If the 8 per cent. had been paid and the 3 per cent. had gone without payment, which upon many occasions it seems that it did, then this reserve fund might be applied for that purpose. The power to redeem the preference shares applies very well to a going company, but it can have no influence or operation whatever when the company is bankrupt, insolvent, and wound up. Now, that state of things has happened, and the accounts are taken, and it is ascertained that there is this money in the till, as I call it. There is a sum to be divided among the shareholders, and for the purpose of that division there is no difference between preference shareholders and others. It is no longer dividend they are going to divide. There is no necessity for resorting to that to equalise dividends for past years when no profit was made, but the money as it stands there is divisible among the shareholders of the company, there being in that respect and for that purpose no difference between preference shareholders and any other shareholders. The only difference was that the preference shareholders got 8 per cent. while there were the means of paying them 8 per cent. When the catastrophe happens, and there is no possibility of there being any gain, profit, or anything else out of which the dividends can be paid, for they can be paid out of profits, then, all that remains to be done is to wind up, to realise what remains, and to divide it among the shareholders equally. The Chief Clerk dealt with it, as I understand, in this way. He decided that the preference shareholders had no preferential claim against the capital, but that, as shareholders, they are entitled to participate in the reserve fund. In my opinion that is the very plain justice of the case, and it is perfectly consistent with every stipulation contained in the articles. The articles authorising the enlargement of the capital gave an advantage to certain persons while the thing was going on, but there is no power given where bankruptcy has happened, and nothing remains but to wind up the concern and divide amongst the parties the fund to which they are entitled. Their rights as shareholders are equal; their rights to receive dividends, when dividends were payable, were different. But that state of things has ceased to exist, and in my opinion the fund is divisable *pro ratâ* among all shareholders, original and preferential, and there is no ground whatever for making any other distribution of the fund which remains.

Mr. MILLAR: The surplus assets of the company will be so dealt with, including the reserve fund. We had better state that.

Mr. BUCKLEY: Certainly.

The VICE-CHANCELLOR: They are all one. It is money in the till, as I have said. It is the property of the company to be divided among the owners, and the owners are the shareholders in equal shares.

Mr. MILLAR: The costs of all parties will come out of the estate.

The VICE-CHANCELLOR: Yes.

SOLDIERS AND THE TELEGRAPH.

At a serious crisis like the present, when the nation is suffering acutely by reason of ill news—news which has travelled, this time none too quickly, partly by hand but chiefly by the medium of Electric Telegraph—it may be useful, as it certainly is natural, that we should once again turn our attention to the functions of that now indispensable adjunct of modern warfare. To say that the telegraph is indispensable is to settle the question of its utility; and this being so all the grumblings in the world on the part of generals in command will not alter the fact. Officers have been heard to say that it is that confounded Telegr aph that makes military operations so difficult; but those very officers, our informant assured us, were particul arly anxious to become better acquainted with their aversion, and to compel their men to follow their example. The truth seems to be that from a soldier's point of view the telegraph is very good for him, but bad for the civilian—or rather, bad for the soldier when used by the civilian. It also hampers the General with orders from home when he would greatly prefer to act on his own judgment—many a good campaign being spoiled by the civil big-wigs at home whose interference is made far too easy by the swift messenger on wires.

It is perhaps not worth arguing against a prejudice which is probably rapidly disappearing under the lessons of experience. It may be worth while to remark, however, that interference from home is no new thing, as the history of the Peninsular War only too plainly reveals; and although our generals in India used to have a freer hand they were not free from responsibility. Responsibility never sat very heavily upon them, it is true; but, on the other hand, wars are nowadays undertaken and planned on the clear understanding that communication with central authority will be maintained uninterrupted. And this alteration brings some clear gain to recommend it. In India the mutiny would not have reached the formidable dimensions it actually attained had the telegraph stretched its friendly arm so far at that time; and in this Egyptian business, where the unforeseen, which is always to be reckoned with in warfare, has actually happened, the original expedition must have been much larger, and the uncertainties much greater had there existed no instant means of demanding reinforcements. Then, again, the purely military services rendered by the telegraph, not only in the field but for keeping touch of outlying posts and reserves, far outweigh the small annoyances caused by that munificent patron of the telegraphs the war correspondent of the newspapers. Indeed, the present Commander of the British forces in the Soudan is said to have got rid of the annoyance by well-nigh suppressing the chief cause of it—not the special wire, but the special correspondent.

On the whole, therefore, it can be proved, if any proof were needed, that while it has had to accommodate itself to the facts of the Telegraph, in the hands of enemies as well as of indiscreet friends, modern warfare has been immensely the gainer by having under its control a medium for the despatch of orders and intelligence so swift in its operation that commanding officers are everywhere within sight and hearing practically of the whole army, as well as of the country for which it is fighting. So far from bearing it any ill-will, military men should, we submit, encourage the Telegraph by every means in their power. We are glad to know that in certain arms of the service the value of the Telegraph has been fully recognised, and that, for example, the Royal Engineers are as a body all expected to be able to work the Morse system when required. The fact that a not inconsiderable number of them have from time to time been employed in the Postal Telegraph service indicates that they have attained proficiency in this part of their important duties. But the Royal Engineers cannot be everywhere; they have other special duties quite as important, often more so, than erecting telegraph lines and transmitting messages. With the advance of the British Army in force towards Khartoum or on Berber, as the case may be, it is conceivable that even if a wire were to follow its movements, there might at certain points be nobody capable of operating upon it. We should be glad to be undeceived if we are mistaken in this; but unless there can always be spared a certain number of Royal Engineers to accompany every separate body of advancing troops, telegraphic communication with the base of operations cannot possibly be kept up. Any way, it seems to us that no harm would be done, and a great deal of good might accrue if a knowledge of the telegraph, which is considered indispensable for Royal Engineers, should be extended to a selected number of every regiment and of every arm of the service.

We urge this with a full knowledge that the Electric Telegraph does not, and cannot always, follow every step of the soldier's march. But visual signalling might; and if it does not it is because there are not a sufficient number of competent signalmen to perform the duty. Visual signalling is closely related to electric signalling; the manner, though not the medium, is often the same, and in any case the best visual signalmen, as the Post Office Volunteers have shown, are men who are most experienced in electrical signalling. The helio-

Digitized by Google

graph is said to be impracticable in the desert because of the *mirage;* whatever signalling is done must therefore be carried on by flag waving, or some similar device. That this is capable of further development and extension we have not the slightest doubt ; and in favourable circumstances messages might be passed on in that way over long distances at a speed slower indeed than the electric telegraph, but vastly quicker than the fleetest horseman could travel. The code is the same ; and after learning its application to one system its adaptation to the other is said to be very easy. By beginning with the electric telegraph there would perhaps be this advantage, that signalling by night, supposing the flashing system not to be available, would still be possible by means of sound. Lord Charles Beresford with a hammer and the engine boiler, and Sir Charles Wilson with a stick and a drumhead or a provision chest, could have spoken to each other quite freely through that anxious night when two miles of Nile river separated them, if only they had learnt the Morse code and how to utilise it. England's wars are almost always out of the beaten tracks of civilisation, and the necessity for being independent of local means of communication is more incumbent on her armies than upon the armies of any other country. The rank and file of English soldiers should be taught the Morse signalling more extensively than is the case at present; and most certainly both visual and electrical telegraphy should form part of every British officer's education.

CORRESPONDENCE.

ELECTRO-MAGNETS.—PROF. ROWLAND'S ADDRESS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : A letter appeared recently in *The Electrician* asking for information about the design of electro-magnets. An answer which appeared was useful as far as it went, but contained no allusion to the magnetic properties of iron. I propose, without interfering with your proposed course on dynamos, to say a few words on this subject, so far as it has come my way.

The only work which professes to deal with the construction of electro-magnets is by Th. Du Moncel, Paris, 1882. It is not of much practical use, on account of the antiquated notation and point of view generally; and its discussions are restricted to cylindrical bars, whose length is 11 or 12 times the diameter. But I have little doubt that a modernised edition of this work would be of much practical utility. The want of generality of view impairs its value for scientific purposes.

It is convenient practically to divide the subject of electro-magnetic induction in iron into three parts :—

1. Properties of the iron itself;
2. Properties of the shape of the iron;
3. The combination of 1 and 2.

Rowland's paper on "Magnetic Permeability, and the Maximum of Magnetism of Iron, Steel, and Nickel,"* gave the first complete account of the nature of the magnetic properties of these metals themselves, and rendered rational discussion of the subject possible. Rowland's experiments were made on rings, which formed closed magnetic circuits of the metal, and thus eliminated the influence of shape. ". . . The results are expressed and the reasoning carried out in the language of Faraday's theory of lines of force." The elementary law assumed is similar to Ohm's law.

The experiments are directed to the determination of a quantity, μ, which expresses the ratio of the field within the iron to the ordinary magnetising force. Rowland's results consisted of expressions for μ in terms of the magnetism per unit area, Q in the paper, $\mathfrak{B}$ as I write it. Two further papers by Rowland appeared in *Phil. Mag.*, Vol. L. (1875), on magnetic distribution. Here the idea of magnetic resistance is formulated, but is only employed in the construction of the theory of distribution.

My attention was directed to the subject in examining the theory of electro-magnetically driven tuning forks. I found that the books did not touch the subject, and there were no means of deriving the properties of magnets from their arrangements. All the theoretical formulæ were practically untried, and depended on uncertain assumptions far too much for practical purposes.

In a paper sent to the Royal Society (abstract in *Proceedings*, No. 223, 1883) I developed a means of defining the properties of electro-magnets under given excitation which is in principle the same as that I still use. This consisted of defining the "magnetic permeability" of the electro-magnet as the ratio of the magnetic induction in it to the external magnetising force.

This was the first attempt within my knowledge to deal with the branch of the subject which I have called (2) above from a practical point of view. Rowland's work had disposed of (1), or shown the way to do so.

Theoretical estimates of the magnetic resistances of different parts of an ordinary magnetic circuit were made in the paper referred to. As far as I can now judge, the estimates of the air resistances were all somewhat too large.

In a paper "On Magnetomotive Force," *Phil. Mag.*, New Series XV., p. 205, March, 1883, and subsequent papers, I have reduced these considerations to a practical system. Magnetomotive force is difference of magnetic potential, just as electromotive force is difference of electric potential. Lately, as will be seen, Rowland appears to have defined magneto*motor* force differently. I define magnetic resistance as,

$$\rho = \frac{\text{Difference of magnetic potential}}{\text{Lines of force per unit area}}.$$

The resistance according to the strict analogue of Ohm's law would be

$$\frac{\rho}{S} = \frac{\text{Difference of magnetic potential}}{\text{Total lines of force}}.$$

As ρ is the more convenient quantity to deal with, S is struck out on both sides. (S = area.)

Now, if we know ρ we can tell what amount of induced magnetism will be excited by given potential, and *vice versâ*.

(Potential $= 4\pi C n$ $\quad 10 C n =$ ampere turns.*)

My experiments have been mainly directed to tabulating ρ in different cases, and I have obtained in this way general expressions by which we can calculate its amount in certain cases.

In the paper on magnetomotive force I first employed the principle that the resistance of a circuit is the sum of the resistances of its parts, which was the first practical attempt to deal with subject (3).

My formulæ for cylindrical bars are given in *Phil. Mag.*, June, 1884, p. 532. I have since been led to doubt the applicability to very short and thick bars.

ρ = magnetic resistance.
l = length of bar.
r = radius of bar.
$\mathfrak{B}$ = lines of force per unit area in equatorial section of bar.

$$f = \frac{\text{focal length of bar}}{l} = \frac{4\pi M}{l \times \text{lines of force.}}$$

M = moment.

μ = permeability of metal: may be represented by Rowland's formula, or more simply by such a formula as

$$300 + 2000\left\{\sin\frac{\mathfrak{B}^\circ}{100} + \tfrac{1}{4}\sin\frac{2\mathfrak{B}^\circ}{100}\right\}$$

(See paper in *Phil. Mag.*, Feb., 1885.)

$\mathfrak{B}$ ranges from 0 through a value (5,000 or 6,000), where the metal is most easily magnetised, up to a saturation point of about 18,000.

* *Philosophical Magazine*, XLVI., Fourth Series (1873), p. 140.

* With respect to the origin of this phrase. In a letter in *The Electrician*, December 9, 1882, I called 10 C n "coil amperes." In a paper on the same subject shortly after Mr. G. Kapp spoke of "ampere turns," a phrase which I have always used since. I call C n "current turns."

Digitized by Google

The winding is supposed uniform from end to end of the bar. The formulæ are—

$$\rho = \frac{l}{\mu} + \cdot 37 \times 10^{-\cdot 0061 \frac{l}{r}} *$$

$$\text{Ampere turns required} = \frac{10\,\mathfrak{B}\,\rho}{4\,\pi} \quad (\pi = 3\cdot 1416)$$

$$f = \cdot 650 + \cdot 440 \frac{\rho}{r}$$

$$\mathrm{M} = \frac{f\,l\,r^2\,\mathfrak{B}}{4}$$

The use of these formulæ may be best shown by an example. I will select one of the bars for which the formula was established, reckoning back, as if the behaviour of the bar were to be found.

$$l = 28\cdot 55 \text{ centim.} \quad r = \cdot 938 \text{ centim.}$$

We will suppose that the required value of $\mathfrak{B}$ is 10,000, that is a powerful magnetism, but below the point where the resistance due to saturation begins to be sensibly felt.

To find μ, when $\mathfrak{B} = 10{,}000$

$$\sin \frac{\mathfrak{B}^\circ}{100} = \sin 100^\circ = \cdot 985$$

$$\tfrac{1}{4} \sin \frac{2\,\mathfrak{B}^\circ}{100} = \tfrac{1}{4} \sin 200^\circ = -\cdot 085$$

$$\cdot 900$$

$$\cdot 9 \times 2{,}000 = 1800$$
$$300$$
$$2100 = \mu$$

$$\text{and } \frac{l}{\mu} = \cdot 0136$$

The second part of ρ is calculated by logarithms.

$$\log \cdot 37 = \bar{1}\cdot 568$$
$$\log r = \bar{1}\cdot 972$$
$$\bar{1}\cdot 540$$
$$\cdot 0061 \frac{l}{r} = \cdot 186$$
$$\bar{1}\cdot 354 = \log \cdot 226$$

adding the two parts of ρ, $\cdot 226 + \cdot 014$

$$\rho = \cdot 240$$

To calculate the ampere turns required,

$$\log 10 = 1\cdot 0000$$
$$\log \mathfrak{B} = 4\cdot 0000$$
$$\log \rho = \bar{1}\cdot 3802$$
$$4\cdot 3802$$
$$\log 4\pi = 1\cdot 0992$$
$$3\cdot 2810 = \log 1910,$$

which is the number of ampere turns required.

The ampere turns actually employed in an experiment which gave $\mathfrak{B} = 10{,}210$ were 1894.

The calculation of f is required for the moment. f is generally a little less than the distance of the poles, as commonly defined, divided by length of bar:

$$\log \rho = \bar{1}\cdot 380$$
$$\log \cdot 440 = \bar{1}\cdot 643$$
$$\bar{1}\cdot 023$$
$$\log r = \bar{1}\cdot 972$$
$$\bar{1}\cdot 051 = \log \cdot 112$$
$$\cdot 650$$
$$f = \cdot 762$$

To calculate M, the moment,

$$\log f = \bar{1}\cdot 882$$
$$\log l = 1\cdot 456$$
$$\log r^2 = \bar{1}\cdot 944$$
$$\log \mathfrak{B} = 4\cdot 000$$
$$5\cdot 282$$
$$\log 4 = \cdot 602$$
$$4\cdot 680 = \log 47{,}900 \ldots \mathrm{M}$$

The value directly found for the moment when $\mathfrak{B} = 10{,}210$ was 48,400.

It must be remembered that the constants of the formulæ are determined so as to agree pretty well with facts through a wide range. Very close agreement with single values cannot be expected.

I have not as yet made experiments on magnets with pole pieces. But there can be little doubt that these will be intermediate in behaviour between rings and bars. I may probably address some remarks to you on dynamo machines, suggested by these considerations, which will not, I think, interfere with your proposed course on the construction of dynamos.

I must now make some remarks on the report of Rowland's British Association address on dynamo machines, and especially on that part of it which is reported in your number of October 25, 1884. The report is so meagre as to be almost unintelligible. It is necessary to allude to it, because it appears that Rowland's present methods are following the same lines that I have been pursuing.

Near the bottom of p. 535 we find the term magnetomo*tor* force. It will be remembered that I had assigned the term magnetomo*tive* force to difference of magnetic potential in March, 1883. In fact, however, I have found the old term, magnetic potential, preferable in practice.

It is not possible to make out from the report precisely what Rowland's magnetomotor force is intended to be. It is first described as being proportional to current turns. Then the total number of lines of forces, ($\mathrm{S}\,\mathfrak{B}$ in my notation) is described as proportional to the current turns and inversely as the magnetic resistance, which is exactly as I state it, except that I keep the potential in the numerator to save the analogy to Ohm's law. Then the different parts of the resistance are enumerated. The air resistances appear to be estimated in a manner nearly according with one of the rules in my Royal Society paper, and the different parts of the resistance are directed to be added together in the manner practised in my paper on magnetomotive force, and subsequent papers. But the final quantity with the current turns in the numerator and the sum of the resistances in the denominator is spoken of again as being the magnetomotor force, instead of being proportional to the number of lines of force, as it probably should be. Then I remember that Rowland's original "magnetising force" was current turns per unit length, and I feel uncertain whether the "magnetomotor force" may not be intended to have a linear quantity in the denominator. We must wait for a fuller report.

The curve mentioned immediately after is the curve which would have for abscissa the induction (as in Rowland's previous curves), and for ordinate the permeability of the magnetic circuit, defined as I have defined it in my Royal Society paper. These curves would bear a reciprocal relation to curves of resistance such as I have drawn (*Phil. Mag.*, June, 1884, p. 334), the one set being always concave where the other is convex. The flatness in the middle of the curves described

* In the summary of formulæ at the end of the original paper $\frac{r}{l}$ is inadvertently printed for $\frac{l}{r}$. In the body of the paper the formula is rightly given.

Digitized by Google

by Rowland is recognised at once in the curves just referred to. No doubt the other curves, with which Rowland compared those he was describing, were the original curves of permeability of his rings.

However, to understand Rowland's intentions completely, we must wait for a fuller report.—Yours, &c.,

R. H. M. BOSANQUET.

PERSONAL SAFETY AND ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I note with considerable surprise that Dr. Stone considers the human body exceptional in its behaviour as a conductor. If he means that it has the property of altering its resistance merely in obedience to the E.M.F. of the testing current, without having undergone any previous physical change, I think he will hardly find confirmation of his views in the case he has quoted. If one thing is shown more than another in Mr. Mance's paper, and in the whole of the discussion—even in the very title of the paper itself—it is that the condition of the conductor at the fault is constantly changing, and the very object of the test is to eliminate the value of the erroneous resistance or E.M.F. caused by the action, principally electrolytic, which is going on, ever-varying, at the fault. I would refer Dr. Stone to Mr. Latimer Clark's beautiful experiment in the wine glass, which is described on page 351 of the *Journal* of the Society of Telegraph Engineers and Electricians, which bears so closely on the subject of Mr. Mance's paper, and also, I venture to think, on the matter under discussion.

I should like to ask Dr. Stone if he can adduce any reason beyond the bare fact that his measurements differ for believing that the human body possesses the property I have named, and also if he does not find a similar result attend measurements made with a comparatively weak current, if the current be allowed to flow for some time, provided the current strength remain constant.

From observations that I have made on my own person I have formed the opinion that the resistance of the body, or at least some parts it, falls with a continued application of a direct current.

The apparent alteration of resistance, in obedience to varying E.M.F., more especially the falling of resistance as the E.M.F. increases, and the lowering of the resistance on the continued application of an E.M.F., are phenomena which are by no means unfrequent in the everyday work of the electrical engineer. As a striking example, I may mention the case of two points in an electric light circuit closely contiguous, between which a rather high difference of potential exists. If the material which is used as an insulator between the two points can be changed physically by the infinitesimal current which passes, the insulation resistance in many cases falls, and you have a powerful current passing where you do not want it, putting you to serious inconvenience.

In reply to Mr. Sennett, I may say that I am constantly, as far as time and opportunity will allow, making experiments and observations bearing upon this very important subject. May I ask that he and others will follow my example? By so doing I feel sure that we should soon collect a vast amount of very valuable information. I am surprised that Mr. Sennett, who has evidently studied physiology, is unable to follow my remarks *re* opposing E.M.F. My reasoning is simply as follows:—We have in every part of the body numerous vessels containing fluids in rapid motion. Taking only the blood vessels, which appear to conduct the best on account of the blood which they contain, we have in every part of the body, side by side, an artery and a vein. Supposing that an electric current be passing through a certain portion of the body in a given direction, it will divide between the artery and vein, passing in the same direction in each. I am here reasoning on the hypothesis that the current passes only in one direction; in each it will create a magnetic whirl around it—or, in other words, a magnetic field. But each conductor —the fluid blood—is in motion in the field created by the other, and, further, they are moving in opposite directions. Therefore I say that a minute E.M.F. will be generated wherever a current passses through a portion of the body containing such vessels. I have no doubt that I shall be told that the E.M.F. must be so small as to be negligible. But is it? Remembering how small are the figures we are dealing with all through, it certainly appears to me by no means so.

Take again the case of the fault in the submarine cable. How small is the surface exposed in the most troublesome faults, and how minute are the currents generated in most cases. I think it will be found that the E.M.F. generated in the body, as I have suggested, and also possibly by the secondary products of electrolysis, bear quite as large a proportion to the currents circulating there as do the polarisation currents, E.M.F., or resistance, whichever form it may take to the ordinary currents used in working and testing the cable.

Now, as to the models and diagrams. I do not think I have suggested anywhere that the resistance of wood models should be measured with a view to obtaining therefrom the resistances of the various parts of the human body; but I do think that the collective ability that has been shown in obtaining such a mastery of the different organs, even to their minutest vessels, &c., should not sit down and say it is impossible to follow the current after it enters the body, because we do not know the proportion that will be taken by the different organs—I use the term in its widest sense—through which it passes. I ask again, Why is it impossible? If we had a bundle of wires covered with cotton, or silk, or other insulating substance, or, what would perhaps form a nearer parallel, a bundle of wires drawn from various metals, would it then be impossible to calculate what proportion of current passed through each? And what are the blood vessels, the blood, the nerves, &c., but conductors, all of high specific resistance, but all varying?

And then as to the use of such plans. Do we not every day hear of some one who has contracted a disease with a name unintelligible to lay understandings, and then we learn that it is something that has happened to some internal membrane or some delicate vessel deeply seated within the body? May it not be that some organ, some membrane, or some vessel, either in health or disease, can withstand a certain current, but if it receives a larger current, though the total current strength itself may be ridiculously small, yet the extra strain caused by the excessive strength of that proportion of the current which passes through that organ may cause a serious or even a vital injury?

I understood Dr. Stone to say "No! it may not!" If I may be allowed, without wearying him too much, or asking him to write a treatise on physiology for my especial benefit, I would ask, Why not?

With regard to Mr. Sennett's remarks as to the action of continuous currents and alternating currents, so far as I understand them, we are at one on the matter, as I think he would find on a perusal of my letter. If Mr. Sennett can produce figures that shall be an accurate measure of the absolute resistance of the body, I will acknowledge myself in error; until he does so I shall maintain that the valuable time spent in measuring from hand to hand and from foot to foot under conditions that could hardly occur in practice might have been more profitably employed.

I trust that it will not be taken that any discourtesy is meant to Dr. Stone or Mr. Sennett by this remark; it is merely the expression of an opinion.

I consider Mr. Sennett's proposal for the slaughtering of animals a very valuable one, and that its adoption, or that of some similar arrangement, would confer a great benefit on those who at present are what I can only term the victims of a brutalising custom. Has it not been shown, however, that the quality of the meat would be deteriorated?

In conclusion, I think that the suggestion of a committee to go into the whole question is also a very valuable one, and I trust that Mr. Sennett will not confine himself in his paper merely to the record of accidents. I would suggest also that a circular addressed to our American friends would be productive of most valuable results, they having so much more experience with high tension currents than we have.—Yours, &c.,

SYDNEY F. WALKER.

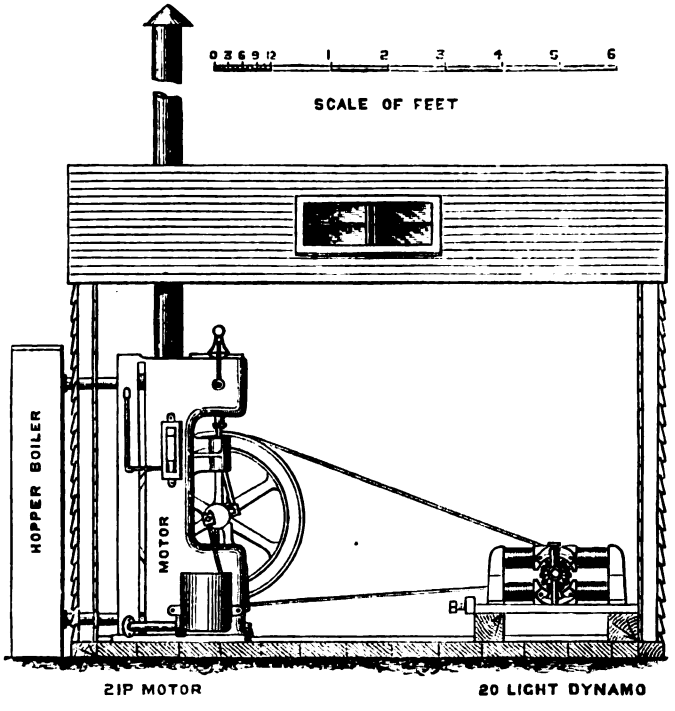
THE DAVEY MOTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: "A Young Engineer" (telegraphic, I presume) in last week's *Electrician* says:—"The Davey motor has been illustrated in nearly all the engineering papers." Will he kindly name a few? I have not seen a description of it in *The Electrician*. If "A Y. E." has read the description in nearly all the engineering papers, why is it, instead of rounding on me, he did not enlighten "A Subscriber," "D.," and myself? Quoting from his letter, he writes:—"Mr. Davey states that he adopts ¼ lead pipe, and I do not gather from his letter that the pipe is used to convey water," Precisely; neither do I. Mr. Davey wites in reply to "D.":—"In my case the *pipes* (not pipe) run up the walls and along the cornice, where they are out of sight (but not lost to memory dear if he uses steam); it matters not how many twists and turns and ups and downs the pipes (not pipe) make."

Unless Mr. Davey has introduced a new element, steam will not travel through a ¼ lead pipe any considerable distance without condensing, a fact "A Y. E." ought to have known. That disposes of the up and down theory of Mr. Davey. Water will not travel unless flow and return pipes are used, and a tank be fixed in the upper part of the house; and my word for it, if "A Y. E." or any one else depended on a ¼ pipe warming his house in mid-winter on that plan he would be precious cold. In Perkins' patent system a ⅞ bore hydraulic iron pipe is used, and the temperature of the water raised to above 300° F., and it circulates under great pressure. Now, a ¼ lead gas pipe would hardly do for this system. Will Mr. Davey furnish our editor with a rough sketch of his motor, and a plan showing the ¼ lead gas pipes in use. I name Mr. Davey, as I feel certain "A Y. E." can have but an elementary knowledge of the laws of hydrostatics or steam. In conclusion, let me inform "A Y. E." that as a rule I do not rashly cut recesses in my walls to bury my pipes without due consideration, and he may rest assured that a 1¼ pipe would not have been used if a ¼ gas tube would have done the work. Apologising for intruding so much on your valuable space.—Yours, &c., PHŒNIX.

[Mr. Davey has sent us drawings of his machine room, from which the following illustration has been prepared. The coke



used is shot into the hopper shown. The motor is of 2 horse-power, driving a 20-light dynamo. We might state, in reply to "Phœnix," that the motor has been twice illustrated in the *Engineer*, but it was not till a day or two before this correspondence commenced that we knew the motor was used for electric light purposes. An illustrated description of the motor shall be given as soon as the pressure on our space from companies' meetings allows us room.]

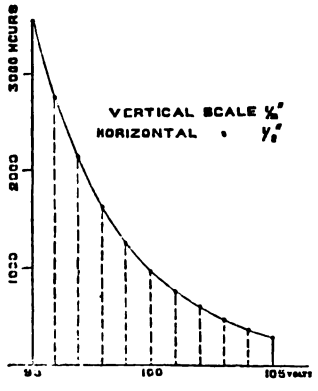
INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: About eight months ago I pointed out to one of your contemporaries many singular agreements between the duration of incandescent lamps—as stated in a German technical journal—and the ordinates of a hyperbolic curve; so it has just occurred to me to look into the particulars given on page 246 of a recent number of *The Electrician*.

It is impossible that the average life of Edison lamps, when subjected to "a very extended series of tests," will be greater than we find it in practice; but it is remarkable, to say the least of it, that whenever a careful record is published the average life of lamps burning at their normal candle-power is always said to be 1,000 hours exactly.

Further, it is in the highest degree improbable that when plotting out the results of an experiment we should get such extreme regularity as I have observed in the figures supplied by Mr. G. Foussat, and I cannot help thinking that your correspondent has been deceived.



I enclose a simple diagram to make my meaning clear.—Yours, &c., WM. H. MASSEY.

Twyford, Berks, 10th February, 1885.

LOSS OF POTENTIAL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should be much obliged if you, or any of your correspondents, could tell me of a practical text-book which deals with the above subject. Is there any book published in the same style as "Day's Electric Light Arithmetic" which takes up this important subject? If there is not, I would suggest that one or more papers on the above in the pages of *The Electrician* would be of immense service to others besides myself.—Yours, &c., E. M. F.

[Professor Forbes is, in the Cantor Lectures now being given before the Society of Arts, dealing somewhat fully with this question. These lectures will be given fully, and not in abstract, in our pages.—ED. *E.*]

ELECTRICITY DEVELOPED BY CONTACT OF SIMILAR METALS.—PRELIMINARY ANNOUNCEMENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In performing some experiments on the conductivity of the human body I observed the following phenomena, and as I can find no reference to the subject in any book on electricity I claim priority of discovery.

I placed a copper wire in my mouth and held another in my hand; the free ends were connected to a sensitive galvanometer. On completing the circuit a deflection took place. I tried this experiment several times and used different sized wires, and always with the same result. The mouth appeared

Digitized by Google

to be positive, and the hand or other parts of body negative, except in the case of the nose, for on placing one wire up the nostril and holding the other in the mouth I obtained a deflection, showing the nose to be positive. I at first thought these effects were due to a current in the body, but found on placing the wires in dilute saline solutions, and even in *distilled water*, the same result took place.

I next employed wires and plates of copper, silver, iron, and zinc. Deflections were always produced on placing one in the mouth and the other at any part of the body ; also on moistening the plates with distilled water, and putting them in contact.

From the above facts it can be seen what two wires or plates of the same metal can produce. In all cases both wires were cut from the same coil and the plates from the same sheet of metal. Nos. 16·20, 30·36 B.W.G. wire was used. The galvanometer was a reflecting one of my own construction, and wound with 36 silk-covered wire ; resistance about 200 ohms.

Trusting you will pardon me for occupying your valuable space with what may be "stale news."—Yours, &c.,

W. A. RUDGE.

Holyrood-place, Plymouth.

[We do not think these experiments are new to the majority of our readers, nor must we expect to find everything that has been observed recorded in books.—ED. *E.*].

THE ANGLO-AMERICAN TELEGRAPH COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : From the notice of the voting at the adjourned meeting of the Anglo-American Telegraph Company published in the daily papers on Monday last, it would appear as if all the shareholders had been invited to give their opinion upon the question brought forward at the meeting whether or not Mr. Cyrus W. Field should be requested to resign. Such, however, was not the case, no attempt having been made by me to obtain proxies from absent shareholders; but the question was unmistakably answered in the affirmative by the majority of the shareholders present at the meeting. The directors, as usual, demanded a poll, in order to record the proxy votes of country shareholders, who had not heard the arguments and discussion, and, consequently, were not in a position to form an opinion. If they had been present probably not one of those votes would have been recorded against the resolution.

It is time that shareholders should take some interest in the management of their affairs, but from long habit they meekly sign the proxy form sent to them by their directors, thus putting a complete check upon any efforts which more active shareholders may think it advisable to take for the improvement of their property. In the case of the Anglo-American Company, I took the precaution to give notice to the directors of my intention to move a resolution requesting the resignation of a particular member of the Board, and asking that a copy of the resolution should be sent to each shareholder with the report, but this very fair proposal was declined on the ground that it was "not in the interest of the company." The shareholders present, however, after hearing the discussion, thought otherwise. It is quite evident that meetings of shareholders are becoming unnecessary, as the opinion of those who take the trouble to attend them is systematically ignored. Much valuable time, and, no doubt, inconvenience to the directors would be saved by the chairman of the Anglo-American Telegraph and other companies printing and circulating an address, together with the intimation that the report and accounts had been unanimously adopted by the directors at a special Board meeting called for that purpose, and consequently a meeting of shareholders was not requisite or desirable.

With regard to the number recorded as having voted at the poll at the meeting last week, most of the shareholders had left the room, or were quite satisfied with the part they had taken in the moral demonstration against the action of the directors, and they felt that it was hopeless to overcome the mass of proxies behind which the directors had so ostentatiously entrenched themselves.—Yours, &c.,

16, Tokenhouse-yard, E.C. WILLIAM ABBOTT.

STRANGE, IF TRUE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Under the above heading you publish in your issue of the 31st ult. an account of the wonderful curative effects produced by wooden "magnets." Instances might be multiplied where imagination and faith in the means used have resulted in the complete cure of all kinds of complaints, particularly nervous diseases; whilst the more mysterious the agency in the eyes of the patient the greater will be the chance of successfully evoking these two most powerful therapeutic agents. Some years ago, Mr. Snape, surgeon dentist, of Chester, having announced his ability to extract teeth painlessly by the aid of electricity, my father, Mr. J. Rogers Bate, fitted up a similar apparatus, consisting of an induction coil, with water regulator in the primary, one end of the secondary attached to the forceps, the other in contact with a metal plate on the arm of the operating chair, so placed as to be grasped by the patient, whilst a simple circuit closer located on the floor enabled the operator to control the flow of current by the pressure of his foot. The most feeble battery power was, as may be supposed, quite sufficient, and under the benign influence of the new local anæsthetic painless extractions became the rule, although, as may well be imagined, the exceptions usually proved excessively painful operations. It was necessary for the coil to be placed so that the patient could hear the slight hum of the contact breaker, or the percentage of failures rapidly rose, whilst so long as the sound was audible it seemed quite immaterial whether the secondary circuit was opened or closed. Nervous people, who believed the operation was going to be painless, usually found it so ; whilst unbelievers either experienced no relief at all, or, as stated above, their sufferings were much intensified.

I remember reading, if I am not mistaken in an old volume of Guy's Hospital *Reports*, of most miraculous cures effected by an electrical arrangement, which went, I believe, by the name of "Perkins' tractors," and were continued when silk cord and tinfoil-covered wood were substituted for the conductors and electrodes of "Perkins'" apparatus.

If I am correct as to the source of my information, Dr. Stone would doubtless be able to furnish some instructive remarks on the subject.—Yours, &c., DOUGLAS C. BATE.

1, Wellington-villas, East Dulwich, Feb. 2, 1885.

Hammond Company Electrical Engineering College.

On Tuesday evening, February 3rd, the President of the Hammond Company Electrical Engineering College entertained at dinner the staff and students of the college at the First Avenue Hotel.

After the usual loyal toasts, Mr. F. C. PHILLIPS proposed "Success to the College."

Mr. HAMMOND, in responding, pointed out that the college was first started to supply a want which was felt throughout the electrical world. There were no skilled electricians combining practice with theory, and after having experienced many disappointments, he arrived at a determination of which the college was the outcome. He pointed out that the study of electricity was in every way a desirable one. It not only gave the intellectual faculties full play, but afforded stimulus to renewed exertion by bringing its votaries face to face with those absolute truths which could not but elevate the human mind.

Mr. ROBERT VENNER, in proposing "The Staff of the College, and the Principal, Mr. H. E. Harrison," referred in high terms to the members of the staff, and testified to the great advantages that he and the other students had derived from the special method of training adopted in the institution.

Mr. HARRISON, who rose to reply amid loud and prolonged cheering, said that although immediately after the formation of the college the electric lighting industry reached its lowest stage of depression, yet all the original pupils had persevered in the profession they had adopted, and it was gratifying to learn that of the Hammond Company's apprentices who had completed their time last September almost all had obtained good appointments.

The toast of "The Hammond Company" was given by Mr. HOFFMAN, and replied to by Sir CHARLES L. YOUNG, Bart., the Chairman, who, after expressing the great pleasure he felt in sitting at the right hand of the President that evening, said that in many of the problems which came before him in his official capacity as Chairman of the Hammond Company he had been helped by the knowledge which his son had acquired at the Hammond College. He felt certain that the City electric lighting contract —the deposit upon which would be paid during the following week— would give employment to even more students than they had at present in the college.

A few songs and recitations brought the evening to a close.

COMPANIES' MEETINGS & REPORTS.

Anglo-American Telegraph Company (Limited).

The ordinary general half-yearly meeting of the proprietors of this Company was held on the 6th inst. at the City Terminus Hotel, Cannon-street, under the presidency of the Right Hon. Viscount Monck.

The SECRETARY (Mr. T. H. Wells) read the notice convening the meeting and the minutes of the last meeting, which were confirmed by the present meeting and signed by the Chairman as correct.

The CHAIRMAN: Gentlemen, it now becomes my duty to move the following resolution:—"That the report of the Directors and accompanying statement of accounts to the 31st December, 1884, submitted to this meeting be and the same are hereby received and adopted, and that the following dividends, less income tax, he now declared—that is to say, first, a balance dividend of 17s. 6d. per cent. upon the ordinary consolidated stock for the year ended 31st December, 1884, making with previous payments 3½ per cent. for that stock for the year 1884; secondly, a balance dividend of £1 10s. per cent. upon the preferred stock for the year ended 31st December, 1884, making with previous payments 6 per cent. upon that stock for the year 1884; third, a first and final dividend of 5s. per cent. upon the deferred stock for the year ended 31st December, 1884." Gentlemen, in moving this resolution I shall, in the first place, congratulate you on one important fact, namely, that your main cables between Europe and America are all in good condition. That fact is an important one at all times, but it is especially so on the present occasion, because at this moment there are four cables of the combined cable companies which are not working, so that the whole work of the Atlantic, as far as our combination is concerned, is done by our cables. I merely mention that fact, which you must bear in mind in considering all the different subjects that will come before you to-day. I will now say a few words as to the figures in the accounts. The revenue account of the half year ended last December shows that the expenses when compared with those of the corresponding period of 1883 have increased £2,493. But in that expenditure of 1884 is included a sum for the repair of the buildings at Heart's Content. The net increase in the expenses of 1884 is £2,493, as I have said, but the expenses attributable to this building are £2,846, so you see if we had not had this extraordinary and inevitable item of expenditure on this building, our outlay for the half year would have been less than for the corresponding period of 1883. I may mention, as a proof of the desire of your Board to keep the expenditure at as low a figure as possible, that the salaries at home and abroad, taken together, show this half year a net decrease of £538, as compared with the corresponding half of a year ago. The revenue for the half year, I am sorry to say, is £12,136 less than that of the corresponding period of 1883. That I apprehend is due principally to the depression of trade which still continues on both sides of the Atlantic, for although our tariff was reduced on the 24th December, 1884, to 1s. 8d. from 2s. a word by the action of the Mackay-Bennett cables, it is not conceivable that the reduction just then would have had any appreciable effect on the half year's revenue; because in the first instance it was only one week in operation, and in the next instance it was in a week not very productive, as it included the Christmas holidays. As I have told you, your cables are working well and in good condition, as far as the main cables are concerned. There are some tributary cables on the other side which are out of order, but that does not interfere with the transmission of messages, as we have the advantage of the Direct and other cables to supply their places. The real question we have before us to-day is the importance of this new competition. I regret to say that, as far as we are concerned, the circumstances to which I have alluded cause this competition to have begun at a very unfortunate period for us. Our competitors, the proprietors of the Mackay-Bennett cables, will no doubt be guided in their future course in a great measure by the result of the operations they are now conducting; and it must be plain to all of you that, four of the competing cables being out of order, the Mackay-Bennett cables must take a much larger proportion of the traffic across the Atlantic than they would do if they had our eight cables to compete with instead of only four. In fact, as I have said before, given a certain number of cables working with equal efficiency, each will take its due proportion of the general traffic. You will naturally ask the Board what we mean to do under the circumstances, and I am afraid at this moment I cannot give you a very satisfactory answer to that question. It is obvious that there is very little use approaching the Mackay-Bennett people with a view to any arrangement or compromise till they have ascertained for themselves and by themselves, and by the operation of their traffic, what their future will probably be. As to any other course, I do not think it would be wise for me to indicate it at present. Your Board, taking the best advice they can get, and watching anxiously the conditions under which the traffic is being conducted, and the development of circumstances, will take that course which they believe to be best for your interests. I do not like to indulge in prophecy; but it strikes me that the ultimate outcome of all these proceedings will not be as favourable to the telegraphing public as they imagine a large number of cables and consequent competition will be. There is an old adage that where combination is possible competition is not very likely to go on at a loss to all parties concerned; and I would fain hope that by some means or other we shall find a way of all making a living out of the Atlantic traffic. But at present the time has not arrived when I believe any effective step could be taken for that purpose. I must ask you, as I have before done, and never without success, to place confidence in your Board, and to entrust them with your interests, believing, as I can assure you is the fact, that they are as anxious to maintain your interests and to make a good income for you as any one in the room can be. There is another burning question which we have had up before now. It was discussed at the last meeting, viz., the amount to be laid aside to the renewal fund. I went so largely into that question at the last meeting that I think it is scarcely necessary for me to weary you by renewing my arguments on the present occasion. But I think the state of circumstances to which I alluded in the early part of my observations, viz., that four cables are at this moment disabled in the Atlantic, ought to exercise considerable influence on the decision you come to on that point. Those cables might just as well have been our four cables as the cables of the Direct, Jay-Gould, and Pouyer-Quertier companies. In point of fact two of the cables at all events that are broken are much newer than any of ours, and therefore it affords a strong example of the insecurity of cable property, and the absolute necessity that exists, if you mean to carry on your work, of having the means at once of renewing or repairing a cable when it breaks down. There is another view of this question, and, though I put it forward at the last meeting, I see so many more present to-day than there were on that occasion, that I may allude to it again—that is, the responsibility which your Board would incur if they paid dividends to the neglect of making provision for keeping your enterprise going on as a going concern. I believe it is very questionable whether—if it is not an absolutely certain rule of law—if Directors, against their own judgment, acting from any pressure from without, pay dividinds which they would not be entitled to pay, which they would not be authorised to pay if they were acting so as to keep the concern going, would not be personally liable to any gentleman who liked to sue them. [A Voice: "Nonsense."] Well, it may be nonsense, but still I believe it may be very good law. Sometimes law appears to be nonsense to people who do not understand it. Therefore, though a gentleman calls out nonsense, I do not think my colleagues are likely, on such an opinion, to run the risk of rendering themselves liable to considerable legal obligations. Your Board have given this subject the fullest consideration, and have arrived at the conclusion that your renewal and reserve fund is not sufficiently large to enable them conscientiously to say that they could deduct anything from the sum annually laid by for the purpose of paying additional dividends. That is the conclusion they have arrived at after having given to it the best consideration which their intelligence is capable of, and having come to that conclusion, we should not be acting honestly by you or our own obligations if we did not announce that decision and adhere to it. I do not know that there is anything else particular that I have to apply myself to at present. We mean, as I have said, to observe this competition, to watch the progress of it, and to mark the development of events, and to take such a course as we think to the best of our judgment will be satisfactory for your interests and the protection of your enterprise. I have nothing more to say except to propose the resolution which I have read.

The Most Hon. the Marquis of TWEEDDALE seconded the motion.

Mr. THOS. SMITH (York) moved, as an amendment, "That whereas the Directors have failed to carry out the resolution and wishes of a large majority of the shareholders at the meeting held in February, 1884, the report now before us, so far as regards paragraphs 3 and 4, be not received; and, first, that £50,000 instead of £75,000 be carried to the renewal account, making the net profit for the past half year £165,426, which with the payment of the interim dividend on the 1st November (which took £52,500), will leave a net balance to the revenue account of £112,926; second, that a dividend be now declared of £1 5s. per cent. on the ordinary stock, making the total amount for the year 3½ per cent.; £1 10s. on the preferred stock, making the usual 6 per cent.; and a dividend of £1 on the deferred stock, to be paid less income tax, leaving a balance of £25,426 to be carried forward, as against £1,676 which the Directors propose." In view of the competition to which allusion had been made, he thought the balance which the Directors proposed to carry forward was very small. The Directors admitted an impending loss of £170,000 of traffic, and they would find the £25,000, which he proposed should be carried forward, of great use in equalising the dividend next year.

Mr. PRUST: That is on the whole of the cables.

Mr. SMITH agreed that that was so. The amendment he had moved was the same as that which he proposed last February, which he was induced by Lord Tweeddale, who then presided, to withdraw in the full assurance and promise of the noble marquis that, if he did so and put it in another shape, and if the majority were in favour of it, it should be carried out. As he had no doubt at that time that Lord Tweeddale would keep his word, he (Mr. Smith) withdrew his amendment and put it as a resolution, which was carried by a large majority. But the shareholders knew the result. Since then they had had another Pharoah to reign over them, who had done quite the opposite of what the noble marquis promised. He maintained that it was within the truth when he said that Lord Tweeddale promised that if the resolution were carried the Directors would carry it out.

The CHAIRMAN: Oh, no.

Mr. SMITH: I beg your pardon; you were not there. He then went on to say that if the Directors' report were adopted as it stood the amount carried to renewal fund would not be, as was stated, £70,000, but with the interest on the investments forming the renewal fund the amount now transferred to that fund would be altogether £85,854, which he considered was not fair to the shareholders. The amount which he had mentioned was only £29,000 less than what was being distributed in dividends. At first the proposal was that 10 per cent. should be taken from the revenue and added to this fund. It was afterwards increased to £100,000 a year, and then to £150,000, and now it was £180,000. He maintained that the Directors' interests, on account of their small holdings and the amount of the fees which they received, were not the same as those of the shareholders. And he also maintained that the Directors did not care whether there was a dividend or not. Since 1880 they had paid the Telegraph Construction and Maintenance Company £600,000, and they were largely interested in that company.

Digitized by Google

A SHAREHOLDER observed that Mr. Smith was making a statement which he (the speaker) knew was not a fact. What Lord Tweeddale said was that the time had arrived when the deferred shareholders ought to be considered.

Mr. PRUST: I wish that time had arrived.

Mr. SMITH trusted that the Directors would see the reasonable nature of his amendment and frankly accept it. He was representing interests at York of £100,000 stock. If his amendment were agreed to, the renewal fund would stand at £700,000. If they went to the Telegraph Construction and Maintenance Company for a new cable without competition there was no doubt that that company would charge them £600,000, but if they offered it to competition he believed they would get it 50 per cent. less.

Mr. BAKER seconded the amendment.

The CHAIRMAN: The amendment is such that I cannot put it to the meeting consistently with the Articles of Association under which we meet. His lordship referred to Clause 164, and said: It is evident by this Article that the duty of setting by a reserve fund and the amount of that fund devolve entirely on the Directors. By Article 165 it is provided that no larger dividend shall be declared than is recommended by the Directors. It is therefore perfectly plain that this amendment cannot be put unless those two Articles are first of all repealed. I must decline, acting under these two Articles, to put the amendment to the meeting.

Mr. SMITH: Then I beg to move that the report be not accepted.

The CHAIRMAN: That is a negative.

Mr. PRUST said he had sent in to the Secretary a notice of motion of a proposed resolution as follows:—"That no more capital should be taken from the renewal fund for the purpose of laying new cables, unless sanctioned by the shareholders in general meeting assembled." He had been a shareholder for a great many years, and at a considerable loss. He was a deferred holder, and his stock cost him about 36, whereas it was now 7 or 8. He quite agreed with Mr. Weaver that it was absolutely necessary that the Company should have a large sum set aside as a reserve fund to protect them, but he thought the time had arrived when they had attained what they wanted. They were now actually the holders of £726,000, the hard earnings of the ordinary and deferred shareholders, because it had been taken from them. It had not come out of the pockets of the preferred shareholders at all. Those gentlemen had their dividends regularly. The interest arising from this £726,000 was about £20,000 or £25,000 a year, and from year to year £20,000 was about the cost of repairs. Four years ago his stock was 32—it was now 7, the reason for that state of things being that he had gone without any interest during those years. He did not wish to take anything from the reserve fund as it now was, but to leave it intact, and to add the interest which it earned to it, and he did not object to their taking in addition £25,000 a year from the revenue. But after that he maintained that enough had been taken out of the pockets of the deferred shareholders. In all railway matters a general meeting had to be consulted before the Directors did anything in the way of spending money; but that was not the case with this Company, and his object was that they should not spend more of this renewal fund unless they got the shareholders' sanction.

Mr. BLUMENTHAL, in seconding the resolution, said that the Articles of Association were one-sided only. It did not necessarily follow, however, that those Articles were right, for common sense often took the place of Articles of Association. He was connected with many companies, and he could show numerous flaws in Articles of Association, which in many cases were made to suit gentlemen sitting on one side of the table. The Board were the shareholders' servants; but, on the other hand, the shareholders were the most obedient servants of the Board. He generally liked a little pleasure for his punishment, and his punishment had been having bought stock in the Company at the top price. The pleasure he would like would be a little dividend. But if the Directors were going on as they seemed to be his hair would become greyer than it was before he got that pleasure, and indeed he would have no hair at all.

Mr. SMITH, of York, referred to Article 53, and said he thought he was within bounds with his amendment.

The SOLICITOR (Mr. Burt): You must read them together.

Mr. SMITH: It may suit you to say that, but I take it as it stands here.

Mr. JACKSON asked what prospects there were of the broken cables being repaired. He thought the present time was very inopportune to urge with insistence on the necessity of discontinuing additions to the renewal fund which the Company now happily possessed—inopportune under the circumstances. But the circumstances, after all, were transitory, for in the course of a month he hoped they would see that at least three of the four broken cables were working again, and the position would then be that not one half of the cables would be employed, and the Board knew better than he did that the renewal fund did not require to be increased by £170,000 a year. The Board in their conduct towards the shareholders seemed to him to pursue a very arbitrary policy, in effect—"we know the business better than you do." He could not agree, as had been suggested, that the Directors would sacrifice the interests of the Company to those of the Telegraph Construction and Maintenance Company, although they were directors of it. On the last occasion he asked how much renewal fund would be required, whether one million would be enough, but the Directors absolutely refused to give the slightest information on the point. He thought the time had arrived when the Board must say something to the shareholders on this matter, in order to avoid dissension and division. The shareholders did not want legal pellets flung at their heads, but conduct which was reasonable.

Mr. CHESTER thought the resolution proposed by Mr. Prust was most important. The Board had now £720,000 in hand, which had been kept time after time from the pockets of the ordinary and deferred shares, and they were in such a position now that they could come to the next meeting and say that a new cable had been laid by the Telegraph Construction and Maintenance Company, and that £700,000 or more of the renewal fund had been paid for that cable. It was true that the Articles of Association gave the Directors certain distinct powers, but he thought that, morally and equitably, such powers were wrong. Could they not say that, although they had this power, they did not wish to act on it; and could they not consent to the resolution of Mr. Prust?

Mr. WM. ABBOTT did not think any one could object to the resolution proposed by Mr. Prust, and he thought the Board would exercise a wise policy if they accepted it. He had now attended meetings of the Company year after year, but every time they came there and made any suggestion which they believed was in their own interests the Directors said, "Oh, we know all about it, and it must be left to the Board." He thought the opinion of a man like Mr. Jackson deserved to have weight with the Board. If it did not, why did not the Directors call such a meeting as that they were now engaged at after the Board meeting, and dispense altogether with calling a meeting of the shareholders? He maintained that the time had now arrived when something must be done for the shareholders—and there were various ways of doing it without interfering with the prerogatives of the Directors. He always at their meetings saw a formidable array of proxies, and Mr. Burt was also present, who flew at the Articles of Association. The shareholders, however, after all, must have rights in the Company in which they had embarked their capital. The Directors were in such a position that they were ignorant of the distress caused to many by receiving very small or no dividends. Looking at the capital of the Company—the whole amount was seven millions, and it was selling in the market for £2,200,000. Deducting the reserve fund of £720,000, there were, according to the market, £1,450,000, representing the value of their four cables, their goodwill, and all their rights. He thought the Directors could accept Mr. Prust's resolution, and that they might promise the shareholders to take into consideration a scheme which might be proposed for the reconstruction of the capital of the Company, and the expunging of some unsatisfactory clauses from the Articles of Association which year after year were the bone of contention between the Directors and the shareholders. He thought if the Company were reconstructed, and the capital divided half and half into debentures and ordinary stock, limiting the addition to the reserve fund to £100,000, instead of £150,000 a year, life would be put into the concern, and a certain portion of the debentures could be drawn every year. If that were done, instead of seeing their stock a drug in the market, they would have a certain amount of the capital as it were drawn every year and cancelled, thus increasing the reversionary value of the ordinary stock, which would give it a considerably advanced price in the market. He believed this would be satisfactory to all parties, and it could be done at very little cost. If it were necessary to fight the new competition, they would be in a better position to fight with a small capital than with a large. As to the reserve fund, he quite agreed with the resolution proposed. It would be madness to allow any more cables, for there were too many already. He must say, however, that he thought it a very fortunate circumstance for the shareholders that their cables were laid by the Telegraph Construction and Maintenance Company, for at the present moment those were the only cables working.

Some discussion took place between Mr. Abbott and the Chairman at this point, concerning a resolution which Mr. Abbott expressed his intention of proposing, and the Chairman said that it would only be in order to hear this motion after the ordinary business was completed.

Mr. ABBOTT finally agreed to postpone his motion.

Mr. SEELEY inquired what was the amount of interest yielded by the investments of the renewal fund in 1884, and the number of *employés* who took £25,000 paid in wages. He thought that in existing circumstances that expenditure should be cut down to the lowest limits.

The Managing Director (Mr. WEAVER), in reply to Mr. Chester, said that the Company now transmitted the whole of the traffic, but they did not get the whole of the receipts. They got a certain proportion, as stated by the agreement between the associated companies. This Company had nothing to do with the repairing of the cables of other companies.

Mr. TROWER suggested, in view of the loss of £170,000 a year by the competition to which reference had been made, whether it was not possible to have an amalgamation between this Company and three other companies that were in the union, so that some portion of this £170,000 might be recovered in that manner.

Mr. JOHN NEWTON said that the interest gained by the renewal fund was added to the renewal fund, but was that in the Articles of Association? If not, he should contend that this interest was part of the reserve and ought to go to the revenue account. He contended that it would be a very small matter to reduce the capital from seven to five millions, in which case it would not be legally necessary to put aside £170,000 to reserve fund.

The MANAGING DIRECTOR pointed out that the amount of capital had nothing to do with the maintaining of the cables.

Mr. NEWTON said that he had spoken of the subject as a matter of law. He maintained that the Articles of Association ought not to be constantly thrown in the faces of the shareholders.

Mr. HUMPHREYS contended that the assessment for the renewal fund ought to come out of the pockets of all the shareholders, whereas £2,600,000 of the capital paid nothing into the reserve fund.

The Marquis of TWEEDDALE: I hope you will allow me to make a personal explanation. I should not have occupied the attention of the meeting had not Mr. Smith repeated here the statement which he made at the last meeting. He stated on the last occasion, and he has repeated it to-day, that this time last year, when I presided over the meeting, I made a promise which was not kept, and that owing to that promise he withdrew his amendment. That statement is absolutely unfounded, and I would remind you of what occurred. He then quoted from the shorthand writer's notes the remarks which he had made in proof of his statement that Mr. Smith's assertion was unfounded; and added that, with

Digitized by Google

regard to the withdrawal of the amendment, he had pointed out that Mr. Smith's amendment was irregular and could not be put.

Mr. SMITH: Our amendments always are irregular.

Mr. BAKER said that though the amendment referred to might have been out of order it was carried by a large majority in the room, but the Directors had not the courtesy even to listen to what was said, and put the same amount to the renewal fund as they did on the present occasion. He repeated emphatically that the recommendation was proposed in that room and carried by a large majority that £100,000, instead of £150,000, a year should be put to the renewal fund; and with regard to the matter having to be dealt with at the next meeting, had the Directors not held the proxies of the Globe Company and the Submarine Trust he believed the shareholders would have beaten the Directors on their own ground.

The CHAIRMAN: It now devolves upon me to make the best answer I can to the different observations addressed to the meeting. Permit me to say, in the first instance, that I am inclined to make every allowance for the feelings of shareholders, particularly deferred shareholders, who come here and find that there is little or no dividend. I will not at all refer to the angry—I had almost said offensive—expressions used to the Board. I shall only make one observation on that point. It has been almost explicitly asserted that your Board sacrificed the interests of this Company to that of the Telegraph Construction and Maintenance Company, and that assertion was based on the statement that we, the Directors of this Company, were largely interested in the Telegraph Construction and Maintenance Company. It is right that you should know the exact facts on that point. The exact fact is this, that not a single Director, as far as I know—and I believe I do know—is interested, directly or indirectly, in the Telegraph Construction and Maintenance Company except one, and that is Sir Daniel Gooch. And what is Sir Daniel Gooch's holding in this Company? His holding—and I believe he has never parted with a share; he is one of the founders of the Company; he has, through good and evil report, stuck to this Company, and is now the holder of £35,000 of your stock. Let me, in the next place, say that the question has been raised by Mr. Newton whether the interest accruing from the reserve fund should be added annually to the reserve fund or treated as ordinary income and distributed among the shareholders. That, I think, is a perfectly reasonable question to discuss. *Primâ facie*, I think the proceeds of the reserve fund ought to belong to the reserve fund; but whether in the circumstances it might not be well to divert it to reserve account is a question we are called upon to consider, and I shall take care that it shall be considered. Mr. Smith has proposed a resolution which I understand is withdrawn. In point of fact, I could not put it, as it would not be consistent with your Articles of Association [laughter]. He alluded to the resolution carried at this time last year, but he forgot to allude to the circumstances of the subsequent meeting. A gentleman on the other side said at the last meeting that if we had not been backed up by the proxies of the Globe Company and the Submarine Trust and so on, the Board would have been beaten. I beg leave to recall to that gentleman's memory what took place. We did not make use of proxies at all. We beat you by the votes of the room. [A Voice: "There was no poll."] There was no occasion for a poll, because the votes in the room were largely in favour of the Directors, 21 were in favour of the resolution, and 33 against it. [A Voice: "Including the Directors."] That having been the case, it is absurd to talk of a resolution passed a year ago when that was rescinded at a meeting six months ago. We have heard a great deal of criticism on the Articles of Association, and Mr. Abbott has stated that the shareholders have rights, as if the Articles of Association instead of being the charter of their rights were a confiscation. It seems to me that gentlemen who came into this Company as shareholders with the Articles of Association before them, knowing what those Articles are, have no right to turn round, and when met by the Board who are appointed to carry out those Articles say that we hurl them at their heads. Are the Board to go through their duties without any compass? The only direction we can have is the Articles of Association, which are well known to the shareholders [no, no]. Then all I can say is that they have acted very unlike men of business in becoming shareholders without knowing what the Articles are. However, the Articles are not like the laws of the Medes and Persians. They can be altered, but not by the mere vague talk of a meeting. The Articles of Association provide a means by which the shareholders, if they are dissatisfied with them, can honestly change them. Do that, and the Directors will bow to your decision. If we considered that the changes you made in the Articles were such that we could not conduct your business satisfactorily under these new Articles we should make our bow, and you would appoint other men to manage for you. But let me tell you that these Articles must be changed by the general body of the shareholders. It is absurd to talk about this meeting, large as it is, representing the whole body of the shareholders, because that is not the fact. There are 5,000 shareholders, all of whom must have a voice in the matter before these Articles are changed, and as long as they are unchanged it is my duty to see that they are not infringed upon, and if I did so I should forfeit any claim to your confidence. The Articles of Association, like the laws of any other body, protect you as much as they do the Directors. Mr. Prust has proposed a resolution that no portion of the reserve fund should be spent in new cables without the sanction of the shareholders at a general meeting. Well, that may be a very good, sound, and proper principle, but it is diametrically opposed to the rules on which you are operating.

A SHAREHOLDER: Do the Articles of Association empower you to spend our money without our authority?

The CHAIRMAN: I must continue my reply. Mr. Jackson asked a question as to the prospect of repairing cables that are down. I believe it is almost certain that they will be repaired; but Mr. Jackson knows as well as I do that this is a very unfortunate time of the year to go into the Atlantic and repair cables, and it is impossible to say within a week or a month when they will be repaired. They are, however, all new cables, and I have no doubt that they will be repaired. I am afraid as to another point I must fall foul of Mr. Jackson. He said we should not be actuated by law, but by equity, with respect to the renewal fund. Well, the Court of Equity would be precisely the machinery that would hold us, if we did not put by a sufficient renewal fund, probably personally liable. I think Mr. Chester asked a question as to the payments made to the companies during the period in which the cables in the "pool" were out of order. That is regulated by the provisions in the contract between the parties on entering into this arrangement of a joint purse. I have not in my mind at this moment the exact period; but I think that if the broken cables are not repaired within twelve months the payment diminishes. At all events a considerable time is allowed for the repair of the cables, and it is just as much in our interests as the interests of others, as it is just as possible that our cables might break as those of our competitors. Mr. Trower asked a question about amalgamation. I suppose it would lead to certain economies if an amalgamation took place, but our experience of amalgamation has not been very favourable, and I know that on the part of our confederates there is a very strong objection to it. I know it was made an essential condition of our union with some of them that they should be kept distinct, not with a view to benefiting the Directors, but with a view to the conduct of the traffic. Still, it is a question perfectly legitimate to discuss and consider, and may be brought forward hereafter. Mr. Newton spoke of the possibility, if the capital were reduced, of our not laying by so much to the renewal fund. But Mr. Newton ought to know by this time that it is not the amount of capital but the number of cables that regulate the amount to be put by to reserve fund. An appeal was made on the part of the holders of deferred stock, as if they were a greatly injured section of the community. But I wish for one moment to recall your attention to the time and mode in which that division between the preferred and deferred took place. That was not in consequence of the action of the Board, but was entirely brought about by a pressure of the shareholders themselves. Let me for a moment impress upon you this fact, that even if the principle was adopted by the Board it was not compulsory for any shareholder to divide his stock into preferred and deferred. If he did it he did it voluntarily, with the conditions before him. At the time the division took place no share was exclusive, deferred, or preferred, but all were ordinary shares; and every ordinary shareholder who changed his shares into preferred and deferred was possessed of an equal quantity of preferred and deferred stock, and if he parted with the preferred stock afterwards he did it for his own convenience. Therefore, I think that the deferred shareholders have no claim whatever on our benevolence. A question was asked as to the amount of interest yielded by the reserve fund last year.

The SECRETARY: The amount yielded in 1884 was about £3 12s. 6d. per cent.

The CHAIRMAN: The wages are between £600 and £700 less than last year. But Mr. Seeley would be the last man to try and get us to take work out of our men for nothing. The number of our *employés* is from 350 to 400.

A SHAREHOLDER: Have the Directors power to alter the Deed of Association without the consent of the shareholders?

The CHAIRMAN: Certainly not. The Articles of Association can only be altered by a special meeting called for the purpose by the shareholders, a majority of three-fourths must concur.

He then put the resolution, and declared it carried by 55 to 21. He further added that he would put Mr. Prust's resolution as a recommendation to the Directors, but he could not put it as proposed.

Mr. SMITH: There is no use of our recommending anything.

Mr. PRUST said that he would stand by the resolution as he had proposed it. That was what he wished.

The CHAIRMAN then put Mr. Prust's resolution as a recommendation to the Board, and said that as far as he could see there were 44 for it and 41 against it, and therefore it was carried.

On the motion of the CHAIRMAN, seconded by the VICE-CHAIRMAN, Sir James Anderson was re-elected a Director.

On the motion for the re-election of Mr. W. G. Cunard, Mr. ABBOTT moved an amendment to the effect that Mr. Cunard be not re-elected, and this was carried by 43 to 23.

Mr. BEVAN (a director) demanded a poll on the question.

Mr. BAKER: Do you intend using your proxies on this?

The CHAIRMAN: Yes ["Shame"].

The Auditors were next re-elected.

Mr. WM. ABBOTT moved a resolution, notice of which he said he had sent to the secretary on the 15th ult., in effect requesting the resignation of Mr. Cyrus Field from the Board, so that some gentleman not identified with any competitive scheme might be appointed to his seat.

Mr. PRUST seconded the motion.

The CHAIRMAN and MANAGING DIRECTOR both spoke strongly against the resolution, and an amendment was moved to the end that Mr. Field should have an opportunity of replying to the charge brought against him. The amendment, however, was lost, and Mr. Abbott's motion carried by 39 to 33, a poll being afterwards demanded and taken.

At the adjourned meeting, held on Saturday, at the Company's offices, Lord MONCK said that the result of the polls for the re-election of Mr. Cunard and the resolution proposed by Mr. Abbott respecting Mr. Field was as follows:—Amount of stock in favour of Mr. Cunard and Mr. Field £2,576,795; number of votes, 34,877; number of voters, 1,068; against Mr. Cunard and Mr. Field, stock, £10,756; number of votes, 165; number of voters, 3. There was thus a majority in favour of Mr. Cunard and Mr. Field of £2,566,039 stock, 34,712 votes, and 1,065 voters; and accordingly he declared Mr. Cunard duly re-elected a member of the Board, and that the resolution moved by Mr. Abbott was lost by a majority of 1,065 to three voters.

The British Insulite Company.

The annual general meeting of the shareholders of this Company was held at the City Terminus Hotel, Cannon-street, on Tuesday last, under the presidency of the Right Hon. E. P. Bouverie.

The SECRETARY (Mr. E. Dolby) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN, in moving the adoption of the latter, prefaced his observations by expressing his regret and that of his colleagues that, through a printer's blunder, the date of the meeting had to be altered from the first Monday in February till that occasion. He had also to express disappointment on behalf of Sir George Richards that in consequence of the blunder in question he was unable to be in his place at the Board, and at the same time that gentlaman's entire concurrence with the course that the rest of the Directors proposed to pursue. He (the Chairman) then said that it was not an agreeable thing for the Directors to have to present accounts to the shareholders of this Company which showed a considerable loss. They had indulged the hope last year that the result of another year's operations would have enabled them to turn the corner. They had some grounds for so thinking, and they were confirmed in that view also by the opinion of a very experienced man in the City—their auditor—whom they requested to examine into the state of the Company's books, and to give his opinion, which was at all times a very good and reliable one. Looking to the question in its main features he (the Chairman) felt convinced that the loss of so much money on the part of this Company was due to the complete failure at present of all efforts for general electric lighting [no, no]. Honourable shareholders might say "no, no," but he must be permitted to express his opinion at any rate, and that was his distinct opinion. He thought he could show some reasons for so thinking. The fact was that all electric lighting business, having at one time promised to be a very big affair, had been entirely crushed out by what was called the Electric Lighting Act of 1882. The public were always jealous of monopolies, but were unaware of the advantage they had derived from having given monopolies in old times to companies when they were embarking in any great enterprise for the public benefit. He ventured to say that if the same jealousy had been felt and the same practical effect given to it at the outset against the railway companies of this country, or against the development of gas or water companies, there certainly would not have been anything like the railway system they now enjoyed in this country, or the advantage that had arisen from supplying their towns with gas and water. It was the very fact of the new outlet of capital promising new and excessive returns that induced people to go into undertakings; but if the public stepped in and laid hands beforehand on any excessive profit made by those who ventured on such new undertakings they stopped the work being carried on altogether. That was the effect of the Electric Lighting Act, which provided that after a certain period the whole of the profits of the Electric Lighting Companies were to be absorbed by the public authorities, and nothing was to be allowed them in respect of the goodwill of the business the Company had still to create. Still, in the first instance, the view entertained by those who started this Company was that their invention would be largely applicable to the purposes of general electric lighting. One electric railway at work in Ireland had resorted to their material for the insulation of its conductors, and for some electric lighting which was done last year at Buckingham Palace and the West of England the people who completed the arrangements had recourse to the Company for its material to insulate their conductors, which was done in a way that could not have been effected by anything else at a similar cost. That circumstance showed quite clearly that if there had been a large demand for the electric light the Company would have greatly benefited by it. But of course their vast source of expected advantage was destroyed for a time by the Act referred to, and they had to look about for fresh business and to ascertain whether it would not be possible to apply their material to various subordinate electric appliances for which it was of great use, and they did so. They had manufactured these to the great satisfaction of the people who used them; but, unfortunately, the demand for anything of that kind, unless it was excessively stimulated by adventitious means, could not be expected to pay, and it had been too limited to return profit to the Company and stand the cost of establishment, manufacture, offices, and so forth. It required a very large area of business to make such an undertaking remunerative. [The Chairman here read one or two extracts from letters received from gentlemen who had used the material, bearing testimony to its quality and its suitability for the purposes of an insulator.] Nevertheless, he said that the result of their experiments had shown that they could not manufacture it except at a loss under the present state of demand. He thought it might have been possible, by dint of advertising, puffing, and canvassing, to have got up a demand for it. They to a certain extent tried that, but they were, of course, hampered by limited means and their unwillingness to squander the money of the Company without a good result, and the consequence had been that the area of business had remained very much as it was, although they had reduced expenditure, &c. The outcome was unsatisfactory, as they would see by the report. They had then, as directors, to consider what had best be done. Instead of making two speeches, he would anticipate what he would have to say at the extraordinary meeting to be subsequently called. They had been landed in a considerable loss, and the question for them to consider was, whether it was for the advantage of the shareholders and themselves to continue to manufacture, and to endeavour, if possible, to turn the corner, and make a fresh call and so recoup their losses. He ought to mention that the Directors had the strongest possible interest in the matter. The gentlemen sitting on his side of the table were not merely there because they had staked their own character upon working the thing respectably and honestly, as he hoped they had done, but they had also a very large holding in the Company. Therefore they had every possible motive as they conceived, in the first place, to try and make the thing a success, and in the next place to form the soundest judgment they could with respect to the future. After deliberating, they came to the conclusion that the best thing for them to do was to recommend the shareholders, as they were to do to-day, to liquidate the Company. Taking their assets at a reasonable estimate they could more than pay everything they owed. One fact in their favour was that they had only two debts, one was to their bankers, and the other was to the Directors themselves. The Directors had never from the first drawn any of their fees, not wishing to embarrass the Company. The item of sundry creditors showed the amount, namely, £2,891, of which £2,600 was due to the Directors. There was, therefore, only £300 due to sundry creditors, and the only debt they owed was that to their bankers. Against that they had some valuable property. He did not propose to put an estimate on the patents, but he might say on the part of the Board, as was intimated in the report, that they still held that those patents might yet become very valuable in a change of circumstances. There was no doubt about the material, its scientific value, and its utility, as tested by experience. Therefore it was quite possible that the patents in better times might become valuable, and they hoped to reserve them for the benefit of the shareholders of the Company, and would hold them in trust for that purpose. They then had their property at the works, which they had bought very cheap, and which was now worth considerably more than they paid for it. There were exceptional facilities there affording access to the river and to the railway, and it was completely isolated, besides being beyond the jurisdiction of the Metropolitan Board of Works, all of which circumstances gave it an increased value. Then they had their machinery, some of which was valuable. They had a small amount of cash, and some arrears of call to get in, and altogether their assets might be estimated at from £7,000 to £8,000. He thought that under these circumstances there would be no further call on the shareholders, but possibly a small return to give them. He concluded by expressing regret that he and his colleagues had not been able to make the Company a success. It certainly had not been due to any want of desire or effort on their part, but rather to those adventitious circumstances already mentioned, over which they had no control—circumstances which he thought it was quite possible might change before long, and give a value to their patents something more nearly approaching what the shareholders originally hoped than what they could possibly reach now.

Mr. MOORE seconded the motion.

The CHAIRMAN, in reply to questions, said that the Directors did not propose to ask for their fees. As to their leasehold property, valued at £2,754, they gave originally £1,800 for it, but they had added to its value by improving the buildings, &c., and they believed it was worth a great deal more. They had 32 years of their lease to run, and the rent was £90.

Mr. PERRING asked whether there would be any further call.

The CHAIRMAN said he could not give an emphatic assurance that there would not be, but he repeated that he believed there would be sufficient assets to obviate that contingency. The wages had amounted for a considerable part of the year to £30 or £40 a week, there being a certain number of men employed at the works; but the item of salaries was not quite what was generally understood by that term. A large portion of the sum disbursed under that head was paid to travellers, of whom they had five at one time working on a salary. Half of the amount might be put down to that. In further reply to questions, the Chairman said that the works had been all stopped, although there was one man looking after them.

Mr. PERRING: Has anybody been looking after the works with a view to buying them?

The CHAIRMAN answered in the negative, giving as a reason that the property had not been put into the market yet. He was inclined to think that, if there was any possible chance of their resuming operations with a probability of profit, it would be very desirable to retain the works, because they would never get such a favourable location again.

The motion was then put, and declared carried.

The meeting was afterwards made extraordinary, and

The CHAIRMAN moved the following resolution:—"That the Company be wound up voluntarily under the provisions of the Companies Acts, 1862 to 1880, and that Samuel Lowell Price, of 44, Gresham-street, in the City of London, chartered accountant, be and he is hereby appointed liquidator for the purposes of such winding up."

Mr. JOHN CLARK seconded the motion, and took occasion to pay a high tribute to the Directors for the way in which they had strenuously endeavoured to save the Company from collapse.

The Hon. CECIL JOHNSTON briefly addressed the meeting, and said that having carefully examined the affairs of the Company he was persuaded they possessed a good concern, and thought it was very unfortunate to go into liquidation at all. He was quite prepared to support the Board with fresh supplies in proportion to his holding, to help them to carry on the works, if the other shareholders would do the same.

The CHAIRMAN pointed out that the wishes of the great body of the shareholders had to be consulted, and he did not think it would be fair to call upon them, since the manufactory was not paying, to contribute anything more at the present time.

After a brief and unimportant discussion the motion was put to the meeting and carried, and the proceedings terminated.

National Company for the Distribution of Electricity.

The second ordinary general meeting of this Company was held at the offices of the Company, 18, Warwick-street, Regent-street, on the 9th inst. The report of the Directors explained the expenditure that had been made on the Metropolitan and Turin-Lanzo railways over circuits respectively of fifteen and fifty miles, which, though yielding no profit,

Digitized by Google

had proved the system. The Directors announce the commencement of a large installation by a company formed by Sir Coutts Lindsay for the house to house distribution of light in Bond-street and the neighbourhood by means of the system of secondary generators. Under a temporary arrangement, part of the Grosvenor Gallery and some neighbouring shops are already lighted by this system. The installation at Turin which obtained the first prize of £400 and a gold medal at the International Electrical Exhibition, has led to important and valuable business. It was also stated in the report that the Company is now prepared to transmit and distribute mechanical power by means of their secondary generators. Looking to the business in hand and that in prospect, the Chairman anticipated that the coming year would yield profitable results to the Company.

The meeting closed with the usual votes.

Submarine Telegraph Company.

The Directors' report shows a result which enables them to add £8,026 0s. 5½d. to the reserve fund, and to recommend a dividend at the rate of 14 per cent. per annum, and to carry forward a balance of £377 18s. The receipts for the six months are less than those of the corresponding period of 1883 by £682 0s. 2½d, owing to the shorter length of the messages transmitted, and to the receipts from the wire leased to the Indo-European Telegraph Company not having been so large as in 1883. On the other hand there has been a small increase in the sum paid by the French newspapers which lease special wires during the night for their correspondence. The expenses for the half year have been £1.969 14s. 2d. more than in 1883, arising from an increase in the cost of repairing the cables and the Company's steamer, law charges, the increased pay to the telegraph clerks and others in the employment of the Company, and the increased sum the Company has now to pay to the French Administration for working the circuits between the French coast stations and London. In the course of the half year there has been inserted in the Company's cables to Ostend and Dieppe two knots of new cable, but fortunately no expense has fallen upon the Company in connection with the Government cables in the North Sea. The new cable laid down by the Post Office to Holland has been in good working order, but the other cable to Holland is now interrupted.

The meeting of the proprietors takes place on the 17th February, at 1 o'clock, at the Company's Offices, 2, Throgmorton-avenue, E.C.

The South Eastern (Brush) Electric Light Company.

The committee appointed at the general meeting held on 22nd December last (consisting of Messrs. W. Hewett, jun., C. H. Stewart, and A. L. Riddell) to inquire into the present position of the Company beg to submit the following report to their fellow shareholders :—

The balance sheet presented at the above meeting being only made up to 30th June, 1884, the committee requested Messrs. Price and Waterhouse, the auditors of the Company, to prepare an approximate balance sheet and report on the accounts for the half year ending 31st December last. From these documents the committee have summarised the following figures, which will show approximately the present financial position of the Company.

	£	s.	d.
To Paid-up Capital	40,615	0	0
By Concessions, Preliminary Expenses, and Expenditure in obtaining Provisional Orders	14,711	4	7
By Colchester Installation and Plant	7,388	7	5
By Stock and Office Furniture and Office Installation	1,941	2	11
By Sundry Debtors, Creditors, and Bills	263	19	5
By Cash advanced to Consolidated Company against Debentures and Shares	7,000	0	0
By Interest due by ditto	691	4	5
By Losses on Working to 31st December, 1884	8,175	16	9
By Cash at Bankers and in hand at 31st December	443	4	6
	£40,615	0	0

Of the total paid-up capital of upwards of £40,000, therefore, practically nothing now remains but the breaking up value of the Colchester installation, the stock, furniture, and office installation, and the debentures and shares of the Consolidated Company. The capital expenditure at Colchester amounts, as above stated, to £7,388 7s. 5d., and the results of the working of the installation since its inauguration are as follow :—

	£	s.	d.		£	s.	d.
Station Expenses to 30th June, 1884	703	1	9	Receipts for same period	226	1	10
Do. to 31st December, 1884	514	18	11	Do. do.	168	9	0
					£394	10	10
				Debit Balance	823	9	10
	£1,218	0	8		£1,218	0	8

The installation has therefore already cost the Company £823 9s. 10d. actual loss on working, without reckoning anything for depreciation of plant (a very large item), or interest on capital sunk, which last item at 5 per cent. since June, 1883, would represent a further sum of over £600.

Under the agreements with the Consolidated Electric Company it would appear that the South Eastern and Provincial Companies are bound to make cash advances to that concern to the extent of £10,000 each. Of this sum this Company and the Provincial have already paid each £7,500. The balance has recently been called up and will doubtless have to be paid. For these cash advances the two companies hold debentures as well as one-fifth each of the nominal share capital of £100,000 (say £20,000 each). The Consolidated Company has been debited with the interest upon the debentures in the books of the South Eastern and Provincial Companies and the amounts carried into profit and loss as an asset. No actual payment to either company has in fact been made, as there are at present no ascertained profits of the Consolidated Company. The committee are informed by the Board that the £15,000 received by the Consolidated Company is now wholly represented by patents acquired by that company, and by the plant and fittings of the factory in Cow Cross-street. As to the intrinsic value of these assets it is impossible for the committee to offer any opinion.

In view of the disastrous results so far, and the certainty that a continuance of the present policy must lead to the calling up of the whole of the unpaid capital, to be followed by the compulsory liquidation of the Company at no distant date, the committee are unanimously of opinion that immediate steps should be taken for the purpose of trying to save what remains of the property of the Company. In the opinion of your committee this can best be done by the voluntary liquidation of the Company forthwith. The liquidators can make any arrangement which may be practicable with the Anglo-American Brush Corporation, and it will be their duty to divide the remaining assets of this Company in as inexpensive and expeditious a manner as possible. Your committee are glad to see that their recommendations are not to be opposed by the Directors, as will appear by the following letter addressed to the solicitors of the committee :—

The South Eastern (Brush) Electric Light and Power Company, Limited, 68A, Cow Cross-street, London, 5th Feb., 1885.

Messrs. Blewitt and Tyler, 79½, Gracechurch street, E.C.

DEAR SIRS: The Directors have to-day further considered the position of the Company with reference to the views entertained by the committee represented by you, and they are prepared to concur with your committee in endeavouring to make such an arrangement with the Anglo-American Brush Corporation as will be satisfactory to the shareholders ; failing which the Directors will not oppose any proposition which may be approved at the adjourned general meeting for either winding up the Company voluntarily, or carrying it on at a minimum expense.—Yours, faithfully,

The South Eastern (Brush) Electric Light and Power Company, Limited.

GEO. OFFOR, Manager.

Your committee in no way coincide with that part of the above letter which suggests a future carrying on of the business.

NOTES.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 13th February amounted to £3,772.

PNEUMATIC TUBES.—The Post Office telegraphs are largely dependent upon pneumatic tubes. In the metropolis no less than 29,801 messages were forwarded by the tubes, against 26,162 by wire, on the same day.

DIRECT UNITED STATES CABLE.—Communication, "*viâ* Direct Cable," with the United States of America, Canada, the West Indies, and Central and South America, is re-established, the main cable having been repaired.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 13th February were £3,056, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

SIXPENNY TELEGRAMS.—The additional number of telegraphists to be engaged by the Post Office, in order to meet the requirements of the increased traffic, is from 1,200 to 1,300. This does not include those operators who may be engaged by provincial postmasters.

N. S. W. TORPEDO AND SIGNALLING CORPS.—The *Daily Telegraph* says that the Torpedo and Signalling Corps of New South Wales consists principally of men belonging to the Electric Telegraph Department, and is regarded by competent judges as a most efficient body.

THE SPANISH EARTHQUAKES.—A telegram received at Madrid on Friday from Jaen, reports that a shock of earthquake was felt the previous day at Torre Del Campo. The church, hospital, and one house sustained serious damage; but there were no casualties among the inhabitants.

LIGHTING OF FRENCH TRANSPORTS.—Among the steamers hired by the French Government for the transport of the troops to Tonkin are the "Château-Yquem" and "Château-Margaux," owned by the Compagnie Bordelaise de Navigation, each vessel being lighted throughout by about 200 incandescent lamps.

GENERAL TELEPHONE COMPANY.—During the week ended February 5th, the Société Générale des Téléphones registered 17 new subscribers in Paris alone, while communication was afforded to 14 subscribers previously booked. The 375f. (£15) paid-up shares, which were quoted at 370f. on February 2nd, rose to par on 9th inst.

ELECTRICAL STREET CARS.—It is said that the electric motor for street cars will soon be an established institution in Cleveland. Arrangements are now being made by the East Cleveland Street Railroad Company to use the Knight-Bentley system on Cedar, Euclid, and Garden streets. The electric lines will, it is said, be in operation within three months.

HOUSE LIGHTING AND HEATING.—Mr. E. H. Johnson, president of the Edison Electric Lighting Company, has his private residence lighted with incandescent lamps. The dynamo is in the cellar, and is said to make so little noise that it cannot be heard on the floor above. A small engine drives the dynamo, and the exhaust steam is used for heating the house.

RIVER STEAMER LIGHTING.—A company has been formed in Paris for running a new line of boats on the Seine. Each of the 32 steamers composing the fleet will be lighted by Bosquet with twenty-two 16-candle incandescent lamps, supplied by a Gramme dynamo modified by M. Raffard, which, at 950 a minute, gives out an E.M.F. of 110 volts at 18 amperes.

ELECTRICAL CHAMBER OF COMMERCE.—The Chambre Syndicale de l'Electricité at Paris languishes for want of sufficient members to give weight to its decisions; but, in view of the new law extending the power and functions of *chambres syndicales*, the president, M. Armengaud, junior, has called a meeting of all interested in reconstructing this syndicate of the electrical industries.

SOCIETY OF TELEGRAPH ENGINEERS.—A meeting of this society will be held in the hall of the Institution of Civil Engineers, 25, Great George-street, S.W., on Thursday, 25th inst., for discussing Mr. Illius A. Timmis's paper, "On the Working of Railway Signals and Points by Electro-Magnets," &c., and hearing a paper "On Constant Electromotive Force in an Electric Light Circuit," by Sir David Salamons, Bart.

ELECTRO-CHEMICAL BLEACHING OF PAPER.—M. E. Hermite has put up, at some paper mills in France, a shop for bleaching paper by the decomposition of chloride of magnesium by the electric current. It appears that a liquid is thus obtained which possesses high decolorising properties, the salt being regenerated as the process of bleaching proceeds, so that, at the end of one operation, the same bath serves for another.

COMMUNICATION WITH THE WEST INDIES AND BRITISH GUIANA.—The cable between St. Croix and Trinidad is interrupted; and, as the cables between St. Kitts and Antigua, between Trinidad and Demerara, and between Antigua and Guadaloupe are not yet repaired, there is at present no telegraphic communication with Antigua, Guadaloupe, Dominica, Martinique, Sta. Lucia, St. Vincent, Barbadoes, Grenada, Trinidad, and British Guiana.

HEAT OF COMBUSTION IN CARBONS.—M. Berthelot and M. Vieille have been experimenting as to the measure of combustion heat in various carbons. A calorimetric bomb was employed, containing three times the amount of compressed oxygen required to effect combustion in air. In the bomb the combustion is complete, lasting for two or three minutes and generating no carbonic oxide. In this manner the measure of heat was obtained with great accuracy.

ELECTRIC EELS.—It is said that a well-known scientific man has ordered from a Liverpool dealer a hundred electric eels for the purpose of studying their powers. Hitherto the nature of the marvellous emanation that has generally been accepted as electricity has not been fully investigated. Although the *gymnotus electricus* is capable of giving a shock not practically distinguishable from that of a galvanic battery, there is now some reason for doubting the identity of this power with a veritable electric shock.

ELECTRICAL APPARATUS FOR PREVENTING COLLISIONS.—The Director of Swedish Railroad Telegraphs has invented an electric apparatus for preventing collisions. The instrument is attached to the rails at certain places and connected by a telegraph wire with the station, where it communicates with a small needle instrument. When a train passes the spot where the instrument is placed, an electric circuit is opened; and the needle indicates the spot where the train happens to be at that moment.

Digitized by Google

NATIONAL TELEPHONE COMPANY.—We have received the February issue of the Dundee district list of subscribers to this company. The first telephone was put up at Dundee in 1879; and there are now in operation in the district 785 telephones and 507 miles of wire, while there are about 1,500 subscribers. We have also received the 11th or January issue of the list for the Aberdeen or Scottish North Eastern district. The first telephone was put up at Aberdeen in 1881; and there are now in operation nearly 450 instruments, the number of subscribers being about 400.

TELEPHONE EXPERIMENTS AT LIMERICK.—In the course of some experiments made at the Limerick Post Office Telephone Exchange, under the authority of the postmaster, Mr. Conway, communication between Limerick and Cork, a distance of over sixty miles, was established by means of the existing telegraph wire connecting the two cities, and with a result proving that conversation can be carried on with perfect success between these points. The articulation is said to have been quite distinct, operators at either end of the line, personally acquainted, being able to recognise each other's voices.

SURPLUS FROM THE PARIS ELECTRICAL EXHIBITION.—A decree of 24th February, 1882, affected the sum of 325,000fr. (£13,000), profit made on the Paris Electrical Exhibition of 1881, to the foundation of a central electrical laboratory; but it appears that administrative difficulties have hitherto prevented the carrying of this useful measure into effect. The most astonishing part of the story, says the *Bulletin International des Téléphones*, is that every one is agreed in recognising its utility, the Paris Municipality having promised to give the necessary land; and yet the matter is not taken in hand.

LIGHTING OF THE EMBANKMENT.—"Alsatia" writes to *The Times* that, since the abolition of the electric light on the Thames Embankment, only half the parapet gas lamps are used, and most of the burners are very much worn. The writer directed the attention of the authorities to the matter in July, and received an official reply on August 15th, to the effect that the question of "lighting by electricity was under the consideration of a committee, and that as soon as their report is received the Board will decide upon the best course to be adopted for the lighting of the Embankment."

CURATIVE ELECTRICITY.—Dr. Berkholz, medical director of the Commandanten-Strasse Baths, Berlin, has successfully treated, by electric current, both rheumatism and various cerebral and nervous affections. He employs both induced and galvanic currents, the intensity of which is regulated to suit individual cases, the electric bath lasting a quarter of an hour. If the action is to be general, one of the electrodes is put in connection with the bottom of the bath, while the other is held by the patient's hands; but if it is to be local, the part affected is placed between two large copper electrodes.

NEW STORAGE BATTERY.—An electrical storage battery similar to that of Faure has been, it is said, designed by Mr. N. S. Keith. It is proposed to employ it for electric lighting, and also to run motors and street tramcars. It is claimed for this invention that fully 70 per cent. of the power generated can be used in an ordinary street car, while with the cable systems only 32 per cent. is available. Very little change is necessary to apply electricity to cars previously drawn by horses. One of the San Francisco systems of street cars is about to be run by the new electric Keith motors and storage batteries.

THE TELEPHONE IN SWEDEN.—According to the *Bulletin International des Téléphones*, Sweden is probably the country where telephonic communication has been developed with the greatest rapidity. At the end of 1882 there were only 1,554 subscribers; but at the end of last year the number rose to 7,737, giving an increase in two years of 6,183. The most important stations are those of Stockholm with 3,796 subscribers, Gothembourg 738, Malmoe 355, Nordköping 208, Sundswall 180, Upsala 139, Visby 113, and Orebro 100, while the telephone is also installed in forty-three other localities of minor importance.

ELECTRIC LIGHT AT BRIGHTON.—At the meeting of the shareholders of the Brighton Grand Hotel Company on the 16th inst., Mr. William Sharp, who presided, stated that they had been trying the electric light at the hotel, in the drawing room and the coffee room. He might state that the result had almost fully answered their expectations—not quite, however, as it was impossible to please everyone. Some of the old ladies, for instance, said it was too cold; and then when they lighted the gas some of them said it was too hot. He thought, however, that the introduction of the electric light might be regarded as a great improvement at the hotel.

IMPERSONATING ELECTRICIANS.—At Wimborne Police-court, on Monday, Henry Everest, *alias* Edison, *alias* Siemens, was brought up on remand, charged with obtaining food, firing and lodgings, to the value of 12s. from Mrs. Caroline King, by falsely representing that he was a son of Mr. Edison, the great electric light originator. On being found out, he decamped from Wimborne and went to Poole, where he was found by Police-Sergeant Cantle playing the same game, having there represented that his father was Mr. Siemens. Prisoner, who is about 21 years of age and the son of respectable parents in Reading, was committed for trial at the quarter sessions.

SHIP COMMUNICATION BY CABLES.—The idea of the French engineer officer for enabling vessels upon the high seas to communicate with the shore by means of existing submarine cables is of too precarious a nature for the project to be of any practical value. He proposes that the cables be supplied at convenient intervals with short branches, with the free ends buoyed so that passing vessels, with the necessary batteries and a key for obtaining access to the wires, may telegraph home. However, experiments to test the feasibility of the scheme are to be undertaken; and several branches are being attached to the cable which connects Algiers with Marseilles.

GENERATORS OR TRANSFORMERS?—Under this head *L'Electricien* reproduces the Italian text of the Turin Exhibition jury award to Gaulard and Gibbs for their batteries. The following is a translation:—Although the transformation, by means of the induction of weak currents into more intense currents, is not a new problem, the jury acknowledges that the latest form given by M. Gaulard to the induction apparatus is very rational, and permits of realising this transformation with but slight loss of energy. Wherefore it hands over to the Società di Generatori Secondari 10,000 *lire* (£400) by way of encouragement to bring to perfection this system, which readily lends itself to the distribution over large areas of all kinds of electric lighting.

BUTTER BY ELECTRICITY.—Mr. A. C. Tichenor has lately patented a process by which a current is passed through milk contained in a vessel of special form, and butter is formed in little balls on one of the electrodes. It is said that to extract the butter from 45 litres of milk the current from a dynamo-electric machine equivalent to that of about 40 Daniell cells for, from three to five minutes, is all that is required. With such a current, the balls of butter are suffi-

Digitized by Google

ciently voluminous to detach themselves from the electrode and float to the surface of themilk; but the butter thus obtained has still to be churned, so as to work the small pieces into a compact mass. We very much question the feasability of such a method of butter-making.

NEW HOLDER FOR INCANDESCENT LAMPS.—We have received from Messrs. Harrison, Cox-Walker, and Co., a new holder, which is so constructed as to make the best possible contact between the loops and the terminals in the holder. At the same time it grips the loops in such a way as to render them less liable to be broken, and also provides an additional support for the lamps where considered desirable. The body of the holder is three-quarters of an inch square, with a deep groove across the middle, in which are fixed flat nipping springs, or pieces of metal, to which the terminals are attached. The loops in the lamps are placed between the springs, two milled-headed screws nip the springs together, and thus hold the loops by the sides perfectly tight, making good electrical contact.

PORTRUSH ELECTRIC RAILWAY.—At the half-yearly meeting of the Giants' Causeway and Portrush Electric Tramway Company held on the 17th inst., the report stated that there was an increase of passengers over the corresponding half of last year amounting to 1,331, with an additional 391 tons of goods and minerals. The receipts were £1,693 5s. 7d., as against £1,554 4s. 7d. last year; and the receipts for the past two years have shown an increase of £338 2s. 8d. The directors recommend a dividend of 3 per cent. on the preference stock, carrying forward a balance of £81 18s. The report was adopted; and, at an extraordinary meeting held subsequently, a resolution was passed approving of a Bill now before Parliament to enable the company to abandon part of their authorised railway and to construct a new one.

FORTIN HERMANN'S CONDUCTORS.—The inventor of this system has sought to combine the advantages of the air line with those of the underground cable. Starting from the fact that the G.P.-covered air line permits of the most rapid transmission possible through the best insulating medium, M. A. Fortin Hermann considers he has found means for counteracting disturbances and atmospheric influences while preserving the dielectric properties. The conductor is inserted in small wood cylinders touching one another by the ends, and thus forming a chaplet or chain, covered by sheet lead or inserted in a lead pipe. This mode of construction permits of placing the conductor indifferently in water, the earth, a sewer, or the air; even under the influence of a high temperature, limited only by the point of fusion of the lead covering, the line is free from atmospheric influences.

LIGHTING AT THE MANSION HOUSE.—The lighting plant for the Egyptian Hall and Saloon of the Mansion House by the Hammond Electric Light and Power Supply Company consists of 142 incandescent lamps in the hall, viz., thirty-four round the edge of the cornice, about 6ft. apart, and 108 on the chandeliers between the columns; with 127 lamps in the saloon, viz., twenty-six in the dome and the remainder on the chandeliers. The current is supplied by two Ferranti dynamos, one to each hall, driven by two 12-horse Clerk patent gas engines, made by Sterne and Co., of Glasgow, the two engines working on to one countershaft. This method, together with driving pulleys having very heavy rims used as fly-wheels, aid greatly in steadying the light. The generating plant is fixed in the cellars of the Mansion House, a work of some difficulty, as they consist of a series of small arches.

REYNIER ACCUMULATORS.—M. Reynier has established at Friburg, Switzerland, a manufactory of accumulators, which are to be of two kinds, one, devised by himself, with zinc and lead electrodes, and the other with lead plates only, after Planté's method. The usual type contains three pairs of plates, and weighs half a cwt. M. Reynier considers that he is able to store up 86,000 kilogrammetres (622,050 foot-pounds), which corresponds to a capacity of 3,440 kilogrammetres per kilogramme of accumulator, or roughly 10,000 foot-pounds per pound (including lead, glass and liquid). As each plate weighs 2·8 kilogrammes, this corresponds to a capacity of 5,120 kilogrammetres per kilogramme, or 16,878 foot-pounds per pound, of lead. Thus, remarks the *Bulletin International des Téléphones*, it has been found possible to get 19 horse-hours out of a ton of lead, a feat hitherto unaccomplished.

WILDMIER ELECTRIC BRAKE.—Successful experiments were lately made at Cincinnati with this new electric railway brake. The tests were made on the Cincinnati, Washington and Baltimore division of the Baltimore and Ohio Railroad, under the immediate supervision of I. H. Stewart, general manager, and I. E. Rose, master of transportation. The special trial was made with a heavy coal train of 10 cars, each weighing empty about 11 tons, and having a capacity of 40,000 pounds. The brakes were only applied to the freight cars and caboose, there being none on the locomotive or superintendent's car, and no hand brakes were used. The loaded train, with full steam on, was put to a speed of 48 miles an hour on a downward gradient of 68ft. to the mile, and was brought to a stoppage in 37½ seconds after putting on the brake, the exact distance run in that time being 445 yards. The brake would act automatically in the event of the train parting.

SOUTH EASTERN (BRUSH) ELECTRIC LIGHT AND POWER COMPANY.—Mr. W. Hewett, jun., and Mr. Braithwaite have issued the following circular:—"Having regard to the Committee of Investigation, it seems to us that, in the interests of shareholders, the sooner this company is wound up the better for all concerned. The letter of the manager referred to in the report of the committee seems to foreshadow an attempt to carry on the company. In order to bring the matter to an issue and to obviate any possible further delay, with its consequent expense, we would ask you to sign and return as soon as possible to Mr. W. Hewett, jun., of 14, Fore-street, E.C., the enclosed requisition. We appeal with the greatest confidence to the shareholders, as we feel sure that it is only by promptly following up the recommendations of the committee, and by stopping the further operations of the company, that any portion of the remaining uncalled capital can be saved."

GUTTA PERCHA FAMINE.—In presence of the scarcity of this, the best known insulating substance, the French Minister of Posts and Telegraphs has sent one of his engineers, M. Séligmann-Lui, to the producing countries, with instructions to report on the possibility of cultivating gutta percha in French Cochin China. The following are the conclusions arrived at in the report to M. Cochery:—Justly anxious about the state of things as regards electrical industry, you hoped that Cochin China might afford fresh supplies; but, unfortunately, this is not the case. Since it is certain that all the countries which produce the guttifers already yield us their supplies, and since excessive demands have in a few years destroyed the reserves accumulated during centuries in the Malayan forests, since the present is without remedy and even the future com-

Digitized by Google

promised, it is necessary to take measures immediately, otherwise a substance will soon be found wanting for which no substitute has yet been discovered.

LIGHTING OF STEAM HOPPER BARGE.—The Liverpool Corporation has invited tenders for electrically lighting the steam hopper barge "Beta," the specification and plans for which have been prepared by the city engineer. Copies of the form of tender may be obtained from Mr. John Denton Fisher, chief clerk, at the city engineer's department. Sealed tenders, which are to be on the official form, and endorsed "Tender for Lighting by Electricity Steam Hopper Barge 'Beta,'" must be addressed to the Chairman of the Scavenging Committee, and delivered at the City Engineer's Office, Municipal Offices, Liverpool, not later than Saturday, 7th March. The successful tenderer will be required to enter into a contract, to be prepared by the town clerk, and, as the Corporation may direct, either provide approved sureties for the due performance of the contract, or deposit an amount equal to 10 per cent. of the contract price; and the lowest or, indeed, any tender will not necessarily be accepted.

JOURNALISTIC PIRACIES.—Our esteemed contemporary, which combines an expressed belief in the originality of its articles with the evident conviction that *The Electrician* was created solely for the purpose of supplying its columns with information of a superior character to its own, would do well to emulate the example of Diogenes, with a view to filling up a possible future vacancy in the editorial department, or, at least, to remember that candour is a virtue possible even in newspaper offices. We have had occasion, more than once, to comment upon the moral obliquity of foreign journals, which have from time to time purloined our matter, with an utter disregard of the laws of *meum* and *tuum*, strongly suggestive of a defective moral training. We regret to see an English contemporary following in their footsteps. Were we given to reprisals, which we are not, we fail to discover any possible means of redress, save that of mild complaint. The old Mosaic rule is debarred us. In justice to our subscribers, our notes must be gathered from sources other than the antique.

YIELD OF BICHROMATE BATTERIES.—The results of the first experiments in domestic lighting by the battery of MM. Buchin, Tricoche et Cie, appear to the *Bulletin International des Téléphones* to confirm the favourable opinion formed of it by our contemporary, who says that, to maintain an incandescent lamp of eight volts, giving an intensity of three candles, it is sufficient to employ a 6-element No. 2 battery, of 65 by 63 mm. surface and 14 cm. high (2½ by 2⅜ by 5½ inches), containing one zinc and four carbon electrodes specially prepared. The first cost is about 25fr. (£1) for Swan lamp and battery; and the expense of maintenance is put as follows:—400 grammes (1lb.) of bichromate of potash at 1fr. 50c. (1s. 3d.) per kilogramme (2·2lb.), 60 centimes or 6d.; 500 grammes (1·1lb.) of sulphuric acid at 40 centimes (4d.) per kilogramme, 20 centimes (2d.); zinc, 50 centimes (5d.); total, 1fr. 30c., or a little over a shilling. After being charged, the battery is said to work for four hours uninterruptedly, so that the cost is 33 centimes, or about 3d. per hour of light. This type of battery will also work for eight hours consecutively with the same zincs, on changing the liquid after four hours action.

ELECTRICAL EFFECTS AT CHELMSFORD.—"Ampère" writes us that, though there is no dynamite outrage at Chelmsford, the "electric fluid in those parts is answerable for many strange effects." He encloses a sensational paragraph from *The Newsman*, entitled "Nocturnal Amusements at Chelmsford," to the effect that "the residents in the neighbourhood of Messrs. Crompton and Co.'s electric light works, Moulsham, were awakened about half-past 3 by the reports of crackers and other fireworks proceeding from the direction of Savernake Lodge, which is occupied by some of the pupils. The true cause of the alarm was, however, stated by "One of the Pupils," in a letter to the *Essex Chronicle*, containing the following explanation:—"Messrs. R. E. Crompton and Co. have lately received a large order for 'polarised galvanometric exploders,' the first lot of which were finished on Thursday. Unfortunately, they were left in the garden of Savernake Lodge 'in series' with a potential indicator, the ammeter of which ran hot in its bearings during the night, thus causing the series of explosions which so startled the good people in the neighbourhood. This accident affords an additional proof, if such were wanted, of the superiority of the suspended over the pivotted needle."

LIGHTING BY SIEMENS IN FRANCE.—The following are the principal establishments in France where Messrs. Siemens Brothers, Paris, have put down lighting plant, with the number of lamps:—A. and C. Berthélemy and Co., spinning mills, Signy l'Abbaye, 75; Blazy Frères, spinning mills, Yerres, 300; Compagnie Générale Transatlantique, steamer "Normandie," Havre, 390; Compagnie des Messageries Maritimes' steamer "Yarra," Marseilles, 184; L. and C. Crepy, spinning mills, Lille, 80; A. Deguerre, mechanical weaving, Maxonchamp, 100; Grandjean et Cie., St. Souplet, Nord, 60; Grands Moulins de Gray, 50; Isaac Holden and Son, wool combing, Croix, 100; E. Lacroix, boot and stay lace factory, Arcis-sur-Aube, 50; Lemaitre, Lavotte, et Cie., weaving works, Bolbec, 500; Schneider and Co., ironworks, Creusot, 160; Vicomte de Tocqueville, Tourlaville, 120; Vachon, Son, and Co., measure makers, Lyon, 160; Van de Weghe et Cie., mechanical weaving, Fives-Lille, 350; Veillage, Chamussy et Bourg, Amplepuis, 200; Vincent and Son, tanners, Nantes, 60. Besides the above, Messrs. Siemens have carried out 33 other lighting installations, bringing the number of lamps for 1884 up to 1,004, and the total number installed in France to 3,868.

ELECTRICAL ACCUMULATORS.—In a paper on this subject before the Société Belge d'Electriciens, M. René Tamine, Ingénieur des Ponts et Chaussées, concludes that a study of the secondary currents generated by the voltmeters of various metals permits (1) of establishing a methodical classification of accumulators, and (2) of practically realising the accumulator which possesses a maximum of electromotive force. When a voltmeter formed with lead, copper, iron, or zinc (leaving the precious metals out of the question) immersed in diluted sulphuric acid, be subjected to the action of a primary electric current, and the effects produced during the discharge, that is to say during the action of the secondary current, it is found that (*a*) the lead is the only one of the above-named metals which produces on the electrodes, under the influence of the charge or the discharge, an oxide insoluble in diluted sulphuric acid, and (*b*) the E.M.F. of the current depends especially, with copper, zinc, and iron, on the activity of oxidation of the spongy layer formed on the negative electrode during the charge. With the lead, on the contrary, the E.M.F. depends especially on the energy of reduction of the layer of oxide formed on the positive electrode under the influence of the primary current. The first of these conclusions supplies an explanation of the phenomenon of polarisation in lead accumulators.

MR. JAMES SIVEWRIGHT, C.M.G.—It is with considerable regret that we hear of the retirement of Mr. Sivewright from the direction of the Cape Government Telegraphs. During

Digitized by Google

the years of his administration, by untiring industry and great knowledge and experience, he made the telegraph service of that colony a thoroughly efficient one. Under his direction the lines have been widely extended, and are in capital order. The staff of operators has been admirably trained, and we are informed that detentions and delays in the transmission of messages are of but rare occurrence. The reason for Mr. Sivewright's retirement is the amalgamation of the Telegraphs with the Post Office. Mr. Aitchison, the present Postmaster-General, is to have control of both the post office and telegraph departments; and Mr. French is to relieve Mr. Sivewright of his duties. The *Wynberg Times* says:—"In 1881 Mr. Sivewright gained the distinction of securing a revenue of 16½ per cent. on the total expenditure of his department, which, under his careful superintendonce and economical working, has become the most prosperous branch of the Public Service at the Cape. There have been so few men combining in one person so many excellent qualifications, that Mr. Sivewright may justly be considered a Colonial *rara avis*; and it is undoubtedly a matter of surprise to the general public that the cessation of his duties should ever have been mooted. The period of Mr. Sivewright's actual service in the colony is, we believe, eight years. His service, however, in this country should count in the calculation of the pension to which he is entitled, and which, in all probability, will amount to £480 per annum."

Orchorowicz Telephone.—In this instrument, which is stated by M. Hospitalier, in *L'Electricien*, to be the most powerful he has heard, the inventor has sought to transmit to a distance speech, as well as vocal and instrumental music, with such clearness that an opera—for instance—may be heard by several people some distance from one another, and without having to bring the receiver to their ears. The system comprises a microphonic transmitter of new and special construction, and of a magnetic receiving telephone, the magnet of which is a solid steel cylinder with a slot down the length of its surface 5 or 6 mm. (¼in.) wide, with two soft iron cores 3 or 4 mm. in diameter about the middle and carrying coils. The latter are enclosed in a kind of flat box, formed of two thin iron plates, one at the top opposite the cores (as in ordinary telephones) and the other at the bottom, screwed to the middle of the magnet. The lower plate is pierced with two holes of a larger diameter than the soft iron cores which traverse it, so as to move freely without touching, these two circular and parallel plates being connected together at their outer edges by a metal crown. In this way, the two plates are only fixed by a point, that which connects the lower plate with the magnet; they form a kind of vibrating box very mobile and elastic, which contains the coils. When the undulating current, modulated by the transmitter, passes through them, it modifies the flow of force inside, increasing or diminishing it. The box closed by the two plates contracts or expands under the influence of these variations of intensity, vibrating throughout its whole substance, thus accounting for the remarkable power of this telephone. It is also capable of acting as a magnetic transmitter, and permits of speaking and hearing in the same manner for a certain distance; but in this case the effect is considerably less marked than with the microphonic transmitter.

Thermodynamic Potential of Batteries.—The following is an abstract of a paper by M. P. Duhem, on "The Thermodynamic Potential and Theory of the Voltaic Battery," brought by M. Hermite before the French Academy of Science:—Simple lines of reasoning, founded on the views which M. Clausius has introduced into thermo-dynamics, show that the heat evolved in any isothermic modification whatever consists of two parts, one equivalent to the work compensated and the other to that which is not compensated. The latter is *nil* if the modification is reversible, but in the contrary case it is necessarily positive. Whence is easily deduced the theorem that "For a system to be in stable equilibrium, it suffices for all practically isothermic modification in that system to correspond with a *nil* or negative work not compensated," this theorem being explained by electrical phenomena. The thermo-dynamic potential of any electrified system, the various points of which are immovable, may be calculated by merely employing Coulomb's law, and that of Ampère for closed and uniform currents. The study of this potential gives in electrostatics the theory of the differences of potential, on the contact of two metals, of Peltier's phenomenon of electrical expansion, &c.; and, adding thereto Joule's law as to the heating of conductors, a complete theory of the voltaic battery, with this principal result, that chemical reaction in the couples would furnish, if the current be not utilised, a quantity Q of heat compensated, and a quantity Q^1 of heat not compensated. The following theorems are capable of absolute proof:—"The heat evolved in the battery in action equals $Q + Q^1$. Voltaic heat, that is to say, the quantity Ari^2, in which r represents the circuit resistance and i the current intensity, equals the heat Q^1, which is not compensated. The excess of chemical heat over the voltaic value is therefore equal to the positive or negative quantity Q." In this manner may be entirely explained the disaccord, pointed out by Favre, between chemical and voltaic heat.

Electrical Transmission of Power.—M. Cornu has reported on the experiments made on 4th March, 1883, at the works of the French Northern Railway, as to the application of M. Deprez' dynamos to the transmission of power along a telegraph wire. The generating machine (a Deprez No. 20) was connected with the receiver (a D Gramme machine transformed) on one side by a short wire of but little resistance, and on the other by a 4mm. galvanised iron telegraph wire, 17 kilometres = 10½ miles long, passing through the Bourget station. These conditions, although not identical with those which are usual in the electrical transmission of power, did not appear to the commission sufficient to detract from the value of the experiments, as continuous and not alternating currents were employed. The results of the measurements are of two kinds—dynamometric, relating to the power transmitted; and electric, relating to the electromotive force developed in the generating and receiving machines. The following are the principal conclusions deduced from the tables of dynamometric and electrical results which were obtained:—"The work absorbed by the generating and transmitted to the receiving machine increased with the speed of the generator, attaining 4½ horse-power for a speed of 1,024 revolutions, against an effective resistance of 160 ohms, representing a double telegraph line 8½ kilometres, or 5 miles long. The gross yield amounted to as much as 37½ per cent. of the work expended; and, if the mechanical motor be allowed for, so as to arrive at the result produced by the successive transformations of energy, the dynamometric result even reached 48 per cent. The table of electrical results shows that the telegraph line practically offered, while the power was being transmitted, that is to say with a current of 2½ amperes, the resistance of 160 ohms which was recorded with a current of 0·01 ampere during the former experiments. This observation appears to sufficiently establish the agreement of theory and practice so far as concerns an analysis of the phenomena of transformation of energy in the circuit."

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 221.)

Second Connection between Electric Force and Magnetic Force.

The equation (15), curl $H = 4\pi\Gamma$, expressing a relation, independent of physical constants, between the magnetic force and the electric current, is an extension of Ampère's results for linear circuits. By Γ must be understood Maxwell's true current—that is, the sum of the conduction current and the displacement current if the body considered be both a dielectric and a conductor, or the conduction current alone or the displacement current alone if the body have no dielectric capacity or no conductivity respectively. All bodies are either conducting or dielectric, or both, and ether is dielectric, so that electric current may exist everywhere. Putting Γ in terms of E by the equation of true current (8), p. 149, where $c\mathrm{E}$ should be $c\dot{\mathrm{E}}$, we get

$$\text{curl } \mathrm{H} = 4\pi k\mathrm{E} + c\dot{\mathrm{E}}, \quad . \quad . \quad . \quad . \quad (19),$$

which is one connection between E and H.

The second connection may be obtained by translating Faraday's law of induced electric force in a linear circuit into a mathematical form. It is remarkable that the ideas of Faraday, who was no mathematician, should admit of immediate translation into mathematical language; a fact due to his dispensing with the direct action at a distance hypothesis, and employing the intermediate mechanism of lines or tubes of force. In popular language, the total E.M.F. of induction round a linear circuit is measured by the number of lines of force taken out of the circuit per second. Here the conventional connection between the assumed positive direction of translation through a circuit, and the assumed positive direction of motion in the circuit must be remembered. Selecting either direction through a circuit as the positive direction of translation, look through the circuit in this direction. Then the positive direction of rotation is right-handed, or with the hands of a watch whose front faces the spectator. Thus, increasing the number of lines of force through a circuit sets up negative E.M.F. round it.

So far in a medium of unit permeability. But when we make allowances for differences in "conductivity for lines of force," that is differences of magnetic permeability, it is not the variation of the magnetic force H, but of the magnetic induction $\mathrm{B} = \mu\mathrm{H}$, which determines the induced E.M.F. The amended statement is that the total E.M.F. of induction round a circuit equals the rate of decrease of the amount of magnetic induction through the circuit. Now, since we have here a line-integral, viz., of the electric force of induction round a circuit, and a surface-integral, viz., of $-\mu\dot{\mathrm{H}}$ or $-\dot{\mathrm{B}}$ over any surface bounded by the circuit, we may at once apply the Version Theorem before referred to (p. 219) and deduce

$$\text{curl } \mathrm{E} = -\dot{\mathrm{B}} = -\mu\dot{\mathrm{H}}, \quad . \quad . \quad . \quad . \quad (20),$$

which of one form of the second relation between E and H.

The following method is also instructive. Since the rate of increase of the magnetic induction at a point equals $4\pi\mathrm{G}$, where G is the magnetic current, as defined by equation (12), we may state the law of induced electric force thus. The total E.M.F. of induction round a circuit in the negative direction equals 4π times the total magnetic current through the circuit in the positive direction. Now compare this statement with the statement regarding equation (15) on p. 220, viz., that the total magnetic force round a circuit equals 4π times the total electric current through the circuit, and change this so as to produce the statement in the last sentence. We must change magnetic force to electric force taken negatively, and electric current to magnetic current. Hence

$$\text{curl } \mathrm{H} = 4\pi\Gamma, \quad . \quad . \quad . \quad . \quad (15)\ bis,$$

becomes

$$-\text{curl } \mathrm{E} = 4\pi\mathrm{G}, \quad . \quad . \quad . \quad . \quad (21),$$

which is equivalent to (20).

We have, in order to simplify the establishment of (20) or (21), avoided mentioning the E.M.F. induced in a linear circuit by its motion in the field, which may or may not be varying independently. The amount of induction added to or taken out of a circuit from this cause may be obviously represented by a line-integral, as it depends upon the rate at which the different elements of the circuit cross the lines of induction. If the induction were of the same strength at all the moving parts of the circuit, and they all moved at right angles to their lengths and also perpendicularly across the lines of induction in the same sense, the total E.M.F. would be of strength = B × rate of increase of area of circuit. But when B varies, and likewise the velocity of the different elements across the lines of B, each element must be considered separately. The amount contributed to the total E.M.F. by an element of unit length equals the component parallel to its length of $V v\mathrm{B}$, if v be the vector velocity. But, if there be current induced, this brings in working mechanical forces, and should therefore be separately considered. At present we return to the case of c, k, and μ constant with respect to the time, and no parts moveable.

In equation (21), E is the E.M.F. of induction only, not the actual E.M.F. There may be in addition electrostatic force, and also impressed electric force. But the electrostatic force is polar; it is derived from a scalar potential. If this be P, the force is $-\nabla\mathrm{P}$. But curl $\nabla\mathrm{P} = 0$, as was before remarked on p. 220 with reference to Ω, consequently the polar force may be included in E in equation (21). Similarly any polar force may be included in H in the previous equation (15). Now in all our equations, from (1) up to (14), not containing any relations between E and H, those symbols mean the actual resultant electric and magnetic force from all causes. Hence, in order that the two equations (15) and (21) may harmonise with the preliminary equations (1) to (14), not only in space when there is no impressed force, but at the places where such exist as well, we must, whilst still using E and H to denote the actual forces, deduct from them the impressed forces in using the relations (15) and (21). So, let e be the impressed electric force, and h the impressed magnetic force. Our two connections between E and H are then

$$\text{curl } (\mathrm{H} - h) = 4\pi\Gamma = 4\pi k\mathrm{E} + c\dot{\mathrm{E}}, \quad . \quad . \quad (22),$$

$$\text{curl } (e - \mathrm{E}) = 4\pi\mathrm{G} = 4\pi g\mathrm{H} + \mu\dot{\mathrm{H}}, \quad . \quad . \quad (23),$$

where the coefficient g of magnetic conductivity is introduced to show the symmetry, and may be put = 0. We have now a dynamically complete system.

The subject of impressed force will be considered in a following section more fully, especially as regards impressed magnetic force, and its interpretation in terms of magnetisation. In the meantime we may define impressed electric force thus. If e be the impressed electric force at a point, and Γ the electric current there, $e\Gamma$ of energy is taken into the electro-magnetic system there per unit volume per second. Similarly, we may define the impressed magnetic force h at a point, by saying that if there be a magnetic current G there, $h\mathrm{G}$ of energy is taken in per second per unit volume by the electromagnetic system there. In general, $e\Gamma$ and $h\mathrm{G}$ are scalar products (*see* equation (5)), having the ordinary signification when e is parallel to Γ, or h to G, in other cases to be multiplied by the cosine of the angle between e and Γ or between h and G.

The Equation of Energy and its Transfer.

We must find the rate of working of the impressed forces, and compare with the dissipativity and with the changes taking place in the energy of displacement and the magnetic energy. Multiply (22) by $(e - \mathrm{E})$ and (23) by $(h - \mathrm{H})$, and add the results. We get

$$4\pi\{(e - \mathrm{E})\Gamma + (h - \mathrm{H})\mathrm{G}\} = (e - \mathrm{E})\,\text{curl}\,(h - \mathrm{H}) + (h - \mathrm{H})\,\text{curl}\,(e - \mathrm{E}).$$

Or

$$e\Gamma + h\mathrm{G} = \mathrm{E}\Gamma + \mathrm{HG} + \frac{1}{4\pi}\{(\mathrm{H} - h)\,\text{curl}\,(\mathrm{E} - e) - (\mathrm{E} - e)\,\text{curl}\,(\mathrm{H} - h)\} \quad (24),$$

by rearrangement. $\mathrm{E}\Gamma$ and HG here occurring have been already expressed in terms of the dissipativity Q, the electric energy of displacement U, and the magnetic energy T; *see* equations (9) and (14). Thus

$$\mathrm{E}\Gamma + \mathrm{HG} = \mathrm{Q} + \dot{\mathrm{U}} + \dot{\mathrm{T}} \quad . \quad . \quad . \quad . \quad . \quad (25).$$

Digitized by Google

On the left side we have the rate of working per unit volume of the actual forces E and H on the currents Γ and G; on the right side the dissipativity, or rate at which energy is being lost from the system irreversibly, producing heat according to Joule's law, and the rate of increase of the electric and magnetic energies, all per unit volume.

Now looking at (24), the left side expresses the rate at which energy is being taken in (reversibly) per unit volume, in virtue of the impressed forces e and h. Therefore the excess of $(e\Gamma + hG)$ over $(E\Gamma + HG)$ must be the energy leaving the unit volume per second through its sides. Now, X and Y being any two vectors,

$$Y \operatorname{curl} X - X \operatorname{curl} Y = \operatorname{div} VXY, \quad . \quad . \quad . \quad (26),$$

or in full, by (5), (16), (17), and (3),

$$Y_1\left(\frac{dX_3}{dy} - \frac{dX_2}{dz}\right) + Y_2\left(\frac{dX_1}{dz} - \frac{dX_3}{dx}\right) + Y_3\left(\frac{dX_2}{dx} - \frac{dX_1}{dy}\right)$$
$$- X_1\left(\frac{dY_3}{dy} - \frac{dY_2}{dz}\right) - X_2\left(\frac{dY_1}{dz} - \frac{dY_3}{dx}\right) - X_3\left(\frac{dY_2}{dx} - \frac{dY_1}{dy}\right)$$
$$= \frac{d}{dx}(X_2Y_3 - X_3Y_2) + \frac{d}{dy}(X_3Y_1 - X_1Y_3) + \frac{d}{dz}(X_1Y_2 - Y_1X_2);$$

using the numbers 1, 2, 3, to denote the x, y, and z components. Let then

$$W = \frac{1}{4\pi} V(E - e)(H - h) \quad . \quad . \quad . \quad . \quad (27);$$

then by (26), with $X = E - e$ and $Y = H - h$, equation (24) becomes

$$\left.\begin{aligned} e\Gamma + hG &= E\Gamma + HG + \operatorname{div} W \\ &= Q + \dot{U} + \dot{T} + \operatorname{div} W \end{aligned}\right\} \quad . \quad . \quad . \quad (28),$$

the equation of energy put in its most significant form. Summing up through all space, W goes out; the total work per second of the impressed forces equals the total dissipativity plus the rate of increase of the total electric and magnetic energy.

W is the vector rate of transfer of energy, or what we before (p. 179) termed the energy current, a vector whose direction is that of the transfer of energy, and whose magnitude equals the amount transferred per second across unit area of a plane perpendicular to that of transfer. Note on p. 179 that impressed forces were said to be not counted; hence as E and H are the actual forces now, the impressed forces are deducted, as shown in (27). The magnitude of W is the product of the strengths of the two forces and the sine of the angle between their directions, and the direction of W is perpendicular to both forces, with the before-stated convention regarding positive directions.

The general nature of the energy current was described in the section "On the transmission of energy through wires by the electric current," p. 178, where, however, only impressed electric force was considered. The same general results apply to impressed magnetic force; energy proceeding from places where such exists, to be dissipated as heat in conducting matter, or to increase the electric and magnetic energies, or to go to other places of impressed magnetic force. But there are great practical differences between impressed electric and magnetic force, owing to the transient nature of magnetic currents and other causes.

Differential Equations of E *and* H.

By eliminating E or H between (22) and (23) we obtain the characteristic equation of E or of H. Put $g = 0$, and eliminate H. Then,

$$\operatorname{curl} \mu^{-1} \operatorname{curl} (e - E) = \operatorname{curl} \dot{h} + 4\pi k\dot{E} + c\ddot{E}, \quad . \quad (29),$$

which is the equation of E. Here e and h, being impressed, must be supposed to be given. μ^{-1} is the operator inverse to μ, that is, in the general case of eolotropy μ^{-1} is defined by the three principal axes and the values $\frac{1}{\mu_1}, \frac{1}{\mu_2}, \frac{1}{\mu_3}$, along them, as was explained on p. 149 in speaking of k. Similar remarks apply to k^{-1} and c^{-1} should they occur.

In space where there is no impressed electric force, and no, or else constant, impressed magnetic force,

$$\operatorname{curl} \mu^{-1} \operatorname{curl} E + 4\pi k\dot{E} + c\ddot{E} = 0. \quad . \quad . \quad (30)$$

In a non-dielectric conductor,

$$\left.\begin{aligned} &\operatorname{curl} \mu^{-1} \operatorname{curl} E + 4\pi k\dot{E} = 0 \\ \text{and,} \quad &\operatorname{curl} k^{-1} \operatorname{curl} H + 4\pi\mu\dot{H} = 0 \end{aligned}\right\} \quad . \quad . \quad . \quad (31)$$

Here propagation of E and of H is by diffusion. And in a non-conducting dielectric

$$\left.\begin{aligned} &\operatorname{curl} \mu^{-1} \operatorname{curl} E + c\ddot{E} = 0 \\ &\operatorname{curl} c^{-1} \operatorname{curl} H + \mu\dot{H} = 0 \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (32)$$

Here propagation is by waves, *i.e.*, propagation of E or H, not of energy.

c and μ self-conjugate; k not necessarily so.

We should note that

$$\dot{T} = \frac{d}{dt}\left(\frac{1}{8\pi} H\mu H\right) = \frac{1}{8\pi} H\mu\dot{H} + \frac{1}{8\pi} \dot{H}\mu H,$$

whilst

$$HG = H\frac{\mu\dot{H}}{4\pi};$$

so for HG to equal $\dot{T}$ we require $H\mu\dot{H} = \dot{H}\mu H$, *i.e.*, μ must be self-conjugate, or contain no rotatory ϵ (equation (3), p. 149). Similarly, for $\dot{U}$ to equal $E\dot{D}$, c must be self-conjugate. But there is no such limitation thrown upon k the electric conductivity operator, nor would there be upon g the magnetic conductivity operator, did such exist. There are other proofs of these conclusions, but the above are very short. There is, however, an objection to be raised against the rotatory conductivity vector ϵ, which want of space does not permit to be mentioned at present.

(TO BE CONTINUED.)

ON THE DESIGN AND CONSTRUCTION OF DYNAMOS.

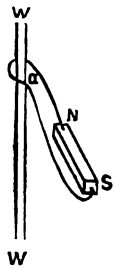
BY GISBERT KAPP.

(CONTINUED FROM PAGE 259.)

This last experiment leads us to the conception that every medium offers a certain resistance to the passage of lines of force, and the inverse of that resistance is called the magnetic permeability of the medium. According to Professor Thompson ("Dynamo-Electric Machinery," p. 38) the permeability of iron is from forty times to 20,000 times as great as that of air. In other words, if we were to surround our straight wire by a cylinder of iron the current would yield within that space from forty to 20,000 times as many lines as if the space contained air. The figures given by Professor Thompson of forty and 20,000 are so widely different that one is inclined to doubt whether anything like a fixed ratio for the permeability of iron and air exists, or can easily be found by experiment. To make such experiment of use for the builder of dynamos it ought not to be undertaken on a small laboratory scale, but with real dynamos. This the author has attempted to do, as will be shown further on, and as an average result he found that wrought iron offers about $\frac{1}{150}$ to $\frac{1}{200}$ of the resistance of air. Cast iron has a considerably higher resistance; generally speaking it requires from 2 to $2\frac{1}{2}$ times the exciting power to get the same number of lines through a piece of cast iron than through an equal piece of wrought iron. In giving these figures the author would point out that he does not consider them as final, but merely as a first attempt to get at something like a tangible result until others succeed in obtaining more exact figures. Experiments of that nature are very difficult, especially on account of the leak of lines through air outside of the dynamo, and also on account of the uncertainty which exists in estimating the degree of saturation. But to return to our straight wire traversed by a current and our small magnet placed near it, somewhere about the middle of its length. Experiment shows that not only that portion of the wire which is immediately close to the magnet affects it, but also the portion above and below, and if we retain our conception that no part of the current can act on the magnet except by a line of force which must actually go through it, we are forced to the conclusion that the lines must be closed curves of three dimensions, that is curves in space. Let in the annexed sketch $w\ w$ be the wire, which for our purpose we can assume to be

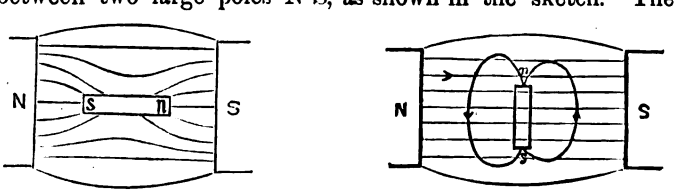
Digitized by Google

infinitely long, then a line corresponding to the current in point *a* must bend downwards, as shown. We can now consider the upper part of the line to lie in a plane at right angles to the wire, and the lower part in a plane more or less inclined to the former. With a straight wire infinitely long the angle of inclination varies between 0 and 90 degrees, but from the experimental fact that a current cannot exert any influence on a magnet pole situated in a straight line with the current, it follows that 90 degrees is the limit through which a line of force can be deflected, and if so deflected its influence is already infinitesimal. The importance of this fact will be seen later on when we come to consider which parts of the winding on the field-magnets are useful and which are useless wire.



The nearer the magnet is to the wire the greater is the force which tends to set the magnet at right angles to the wire. To explain this we can either assume that the force exerted by each individual line is the same, but that more lines are pulling at the magnet when the latter is close to the current, or we can assume that the same number of lines pass through the magnet whatever its position, but that each individual line is the stronger the more closely it encircles the wire. Either conception leads to the same thing in the end, but the latter has the advantage of being more easily applicable to complicated cases. We can put it also in this way:—The shorter the total length of a line of force and the greater that proportion of it which goes through iron, the stronger will the line be. From the fact that magnet poles of the same sign repel each other we conclude that parallel lines running in the same sense repel each other. This follows also from the experiment by which the lines round the wires are made visible; for if the inner lines were not to repel the outer ones the latter would not be found at so great a distance from the wire. The attraction of magnet poles of opposite sign points to another quality of the lines of force, viz., that each line tends to shorten itself; and this is also the reason why the lines round a free wire are concentric circles. The circle is of all curves possible the shortest for a given diameter. Each line has a tendency to tighten itself up into the smallest possible circle, but this tendency is opposed by the repulsion from neighbouring lines within the circle, whilst lines without it assist the tendency. Each line, therefore, takes up a certain position of equilibrium where its own force of contraction is exactly balanced by the repulsion from the other lines.

When lines cross each other at an angle they tend to become parallel, but of opposite sense, and thus to eliminate each other. This can easily be proved by placing a small magnet between two large poles N S, as shown in the sketch. The



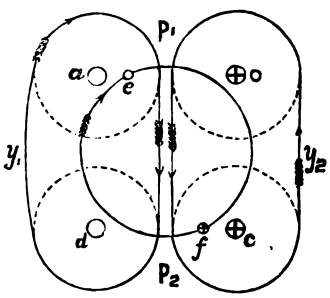
magnet will turn on its centre until *s* points to N and *n* to S, when the lines originally belonging to it will have vanished, being eliminated by the lines between the large poles.

The above remarks are a kind of list of some of the properties of magnetic lines of force. It will be useful to briefly sum them up.

1. A line must be a closed curve. 2. It has a tendency to shorten itself, becoming the stronger the shorter it is. 3. It need not be a plane curve, and part of it can be bent off at any angle short of 90 degrees. 4. It finds less resistance in iron than in air, and a greater number of lines can run through iron than through an equal space of air. 5. Parallel lines of the same sense repel each other, and parallel lines of opposite sense attract and eliminate each other. 6. Lines crossing at an angle have a tendency to set themselves parallel, but in opposite sense.

It is well known that if a closed wire is moved so as to cut lines of force a current flows in it as long as the movement lasts. Suppose we have a straight wire traversed by a current, and we approach to it another straight and parallel wire forming part of a closed circuit, then the current induced in the latter will be in opposite direction to that in the fixed wire, and if we remove the wire the current will be in the same direction. What the reason of this phenomenon is we cannot say, and it will probably remain as much a mystery as the invisible cause of the force of gravitation; but for our purpose it suffices that we know this effect does take place and can be utilised.

Imagine that, instead of having only one fixed wire, we place for such wires *a b c d* round a circle (Fig. 1), the wires being perpendicular to the plane of the paper. Let the current go from the observer in *a* and *d*, and towards the observer in *b* and *c*. To make the drawings plain in this and all the following diagrams, a current directed downwards is denoted by a dot in the centre of the little circle representing the wire, and a current directed upwards by a cross. The lines of force, of which for the sake of clearness only one is shown to each wire, will, according to the assumption made in the previous article, run round *a* and *d*, in the direction of the hands of a watch, and round *b* and *c* in opposite direction. The lines round each wire would be complete circles if no other wires were near; but through the influence of other wires their shape is altered. Thus, where the lines belonging to *a* and *d* come near each other they are in opposite sense; they attract and eliminate each other. The same happens on the other side between *b* and *c*, and to make this clear in the drawing those portions of the lines which have been mutually eliminated are dotted, the rest being shown in full.



Now, let a movable wire revolve in the direction of the arrow between the four fixed wires. Whilst passing from *a* to *b* this wire cuts a number of lines belonging to these two fixed wires. Since the lines are most dense close to *a* and less so towards the middle between *a* and *b*, the wire *e* cuts lines at a decreasing rate in receding from *a* until the middle is reached, and from there towards *b* again at an increasing rate as it approaches this wire. In receding from *a* the current in *e* must be in the same direction, viz., downwards, and in approaching *b* it must be in opposite direction to that in *b*, therefore also downwards. We see that although the rate of cutting of lines between *a* and *b* is variable the general effect is to produce a current downwards. Between *b* and *c* no lines are cut if we suppose that all the lines have been mutually eliminated, but between *c* and *d* lines are again cut. The wire in receding from *c* has induced in it an upward current, and the same effect takes place in approaching *d*. We can now establish a rule for the direction in which a current will be induced by the cutting of lines of force. *Imagine a man substituted for the wire and his face turned so that the lines run towards him (which is equivalent to looking towards a N pole), then if he move laterally to the left the current will flow from his feet to his head. If he move laterally to the right the current will flow from his head to his feet.*

If, instead of having only one wire, we have two diametrically opposite, *e* and *f*, and join them at one end by a cross connection, we could arrange at the other ends rubbing contacts between the points *a b* and *c d*, by which the current induced in the two wires could be taken off. We should then have an intermittent current, but always in the same direction. Suppose that instead of only two wires we have a great number all round the circumference, and join them up in the manner of a Hefner-Alteneck armature and commutator, the current would be continuous. It will of course be clear that the apparatus here described would make but a very poor machine for the generation of electric currents; from a scientific point of view it is, however, interesting to see how the simple phenomenon of induced currents between two wires could be turned to account for producing continuous currents without the aid of any iron or permanent magnets. The effect of the machine, even if a very strong current from an independent source were sent through the fixed wires, would

Digitized by Google

be very feeble; but assume that instead of only one wire in each of the four corners we were to have several, joining them up into a coil between a and b and between c and d; and assume also that, in order to reduce the magnetic resistance, we were to put soft iron into the path of the external lines of force, joining $P_1 Y_1 P_2 Y_2$ by an iron framework, we should thus arrive at the usual form of a dynamo with pole pieces $P_1 P_2$ and yokes $Y_1 Y_2$, and the current produced would be very strong.

(TO BE CONTINUED.)

THE MOST ECONOMIC POTENTIAL DIFFERENCE TO EMPLOY WITH INCANDESCENT LAMPS.

BY PROFESSORS W. E. AYRTON, F.R.S., AND JOHN PERRY, M.E.

As stated by Mr. Gordon in your issue for the 7th inst., and as stated by others over and over again, a mere list of efficiencies of incandescent lamps without any tests of the life of the lamps at the various candle-powers is at the present time nearly useless.

The experiments made by Sir William Thomson, and by ourselves, in 1880, in the earlier days of incandescent lamps, on the number of candles per horse-power given by the various types of lamps for various potential differences maintained at their terminals, were interesting enough in leading to the law of the rapid increase of the light emitted relatively to the power expended electrically on the lamps. But such experiments by themselves cannot possibly enable us to decide on the commercial value of any particular incandescent lamp, and therefore their repetition *alone* over and over again, by various experimenters since 1880 for incandescent lamps, has added but very little to our knowledge.

A striking exception must however, of course, be made to this statement in reference to the splendid series of experiments made by Captain Abney and Lieut.-Colonel Festing, since, although these experiments have been made without reference to the life of the lamps, they were made for the object of determining, among other things, the simultaneous efficiency for different parts of the spectrum, and therefore have great value in helping us to judge how far it may be possible to use an incandescent lamp as a standard of white light.

In your issue for January the 31st a table of values of the life of a 100 volt Edison lamp for different potential differences is given by Mr. Foussat. Objection has been taken to these results by Mr. Massey, in your issue for the 14th inst., because the points lie very regularly in a curve; but if it be remembered that the results are stated to be the *average* of a very extended series of tests, and that it is quite possible that Mr. Foussat may have employed the perfectly legitimate process of correcting his results by the most probable curve connecting them, it is not quite certain that this great regularity is necessarily a proof of inaccuracy. Some days ago we applied to Mr. Foussat, asking him whether he had also the results of experiments on the efficiency of the same type of 100 volt lamps, as our own experiments on the efficiency of Edison lamps had been made with 55, 108, and 110 volt lamps. As, however, he had not such results, and as his tests of the lives are the only ones that we now have, and very possibly will have until the completion of the excellent work at present being carried out by the Electric Lighting Jury of the Health Exhibition, we must endeavour to combine his results of life with results previously published for efficiency. To enable us to do this we will assume that the life of 1,000 hours given by Mr. Foussat for his 100 volt lamp when used with a potential difference of 100 volts would be the same as that for our 108 volt lamp when employed with a potential difference of 108 volts, or, in other words, we may regard lives given by him as correct for 108 volt Edison lamps when each potential difference is multiplied by $\frac{108}{100}$.

To ascertain the most economic potential difference we must proceed as follows: Let $f(v)$ be the function connecting life in hours with the number of volts constantly kept on the lamp, $\theta(v)$ the function connecting the number of candles emitted by one lamp with the potential difference in volts employed, let p be the price in pounds paid to buy one lamp, and n the number of hours per year that a lamp is kept burning, then

$$\frac{p \times n}{f(v) \times \theta(v)}$$

stands for the cost per year, per candle, as far as the purchase of lamps is concerned.

Next let H stand for the cost in pounds of an electric horse-power per year for the number of hours electric power is employed. H will not, as mistakenly supposed in the Electric Lighting Act, be proportional to the number of hours, but will be of the form of $h + F(n)$, where h is a constant independent of the number of hours, and depending on the rent of the site, capital expended in engines, dynamos, leads, &c.; and $F(n)$ is a function of the number of hours that electric power is required, and depends on the cost of coal, superintendence, &c. If the light were only required for one or two hours in a district where rent was very high, h would be the all important term, and $F(n)$ would be unimportant; whereas, if the electric power were required for various purposes for, say, 15 or 20 hours out of the 24, in a place where rent was low but coal dear $F(n)$ would be the important item in the yearly bill for electric power supplied. Let $\phi(v)$ be the function connecting watts used per candle with the number of volts employed at the terminals of a lamp, then

$$\frac{H}{746} \times \phi(v)$$

stands for the cost per year, per candle, as far as the production of electric power is concerned.

The total cost, therefore, per year, per candle, is

$$\frac{p \times n}{f(v) \times \theta(v)} + \frac{H}{746} \phi(v) \text{ pounds} \quad . \quad . \quad A$$

and we must find the value of v that makes this a minimum.

There are two ways in which such a problem can be solved, the one a graphical method, the other an analytical method; and as the former is especially suitable for students, we will give that one first. This consists in drawing three curves to represent, 1st, $f(v)$ in terms of v; 2nd, $\theta(v)$ in terms of v; and, 3rd, $\phi(v)$ in terms of v. From these curves the values of $f(v)$, $\theta(v)$, and $\phi(v)$ are determined graphically for some one value of v, and from them the value of the above expression, A, calculated for this value of v. The values of $f(v)$, $\theta(v)$, and $\phi(v)$ are next determined from the three curves, all for one value of v, but differing from the value of v previously selected, and again the value of the above expression, A, is calculated. After this has been done for several values of v a fourth curve is drawn connecting the various values of the expression A with the corresponding values of v, and then, by inspection, it is easy to see for what value of v the expression A has a minimum value.

The following is the result so obtained for the 108 volt Edison lamps burning in the Finsbury Technical College:—

p is taken as five shillings, or £0·25;

n as 560 hours the time per year the lamps are lighted approximately;

H as £5, which, considering that the cost of the steam engine, price of coal burnt, wages of the engine driver and stoker at the college have to be mainly debited to the driving of the workshops, supplying power for dynamos worked for experimental purposes, &c., amply covers, per horse-power, the yearly interest on what may be called extra plant and the extra cost of supplying electric power for lighting during the 560 hours per year.

Then the value of v, which makes A a minimum, turns out to be about 106 volts, and on account of the flatness of the curve connecting the expression A with v we see that in this particular case the annual cost of supplying light is only increased by 3·5 per cent. if the potential difference between the mains if kept diminished to about 104.8, or kept increased up to about 108 volts. Also that keeping the potential difference diminished to about 104·5 or increased to about 108·5 volts increases our total annual cost of lighting by 5 p.c.

In your next issue we will give some other results obtained graphically, as well as the details of the method of solving this problem analytically which we have employed.

THE DISTRIBUTION OF ELECTRICITY.

Electrical engineers have had their attention of late fixed upon overcoming the difficulties attending the distribution of electricity over large areas far more than upon any other problem connected with electric lighting operations. Professor Forbes in his recent Cantor lectures has dealt very fully with the whole subject, and has suggested directions in which to work. The conclusion at which he has arrived—and in this conclusion he is supported by Dr. Fleming and others who have paid considerable attention to the subject—is that the future of electric lighting depends to a considerable extent upon the ability of electric light engineers to solve the problems which surround the transmission of electricity of very high E.M.F. Professor Forbes maintains that, with due regard to insulation, to the position of the mains, and in other directions which need not be discussed in detail, there should be absolutely no more danger from the use of electricity of high E.M.F. than from the so-called low pressure electricity as now permitted. This conclusion is probably correct, as it is difficult to see where the danger would arise in a well designed system, inasmuch as the E.M.F. at the point of utilisation—that is, at the terminal of the distributors entering the house—would simply be that required by the lamp used, which at the present time is not more than 120 volts. Although it is easy to point out that the use of electricity of high E.M.F. is very much more economical than the use of electricity requiring large conductors, we are not yet in a position either to insulate or to determine the best method of carrying our conductors. At the recent Philadelphia Exhibition a large number of systems for the carrying of conductors underground was shown. A tolerably full description of these various systems has just been issued by the examiners and published by the Franklin Institute. The full report is very lengthy, and but little information is to be gained from the comments of the examiners; in fact, we are left very much to draw our own conclusions as to the best system after having compared the descriptions. No tests were carried out by them owing to want of time and absence of facilities; therefore we have still to wait for such tests to ascertain the real value of any of the systems, except in such cases as have already been carried out upon a practical scale. Of these the Edison and the Brooke systems are the chief examples. The system which has had the most extended trial is that of Mr. Edison, and, as will be seen by a reference to Dr. Fleming's paper, a great many difficulties have been encountered and overcome; but it is allowed that, were a new system of mains to be adopted they would be laid on a different plan.

It must be remembered also, in considering the report of the Philadelphia Exhibition, that the examiners were not called upon to determine solely the value of underground systems for lighting purposes, but for the transmission of electricity generally. In the preface to their report this is distinctly put, as will be seen from the following paragraphs, the last of which is specially valuable as showing our ignorance of the subject:—

"Although the examiners abstained as far as possible from entering into the comparative merits of the systems, the examiners considered it advisable to note the obvious merits and demerits of each system, so far as they had means of judging. The points upon which they have commented are such as a sufficient experience of analogous contrivances enabled them to judge of from the bare statements and descriptions. In no case was it possible to state from actual observation of the working of any of these systems that they did or did not fulfil what was claimed for them.

"Your examiners are of the opinion that during the experimental stage of underground conduit construction for electric currents it is desirable, in the interest of the community in which such conduits are laid, that the latter be capable of use for as many different purposes and by as many different companies as possible; and also be capable of inspection in every part, and removal or replacement with the greatest possible rapidity and the least possible obstruction to the public highways.

"The rapid advance of electrical science in the past renders it nearly certain that the next few years will witness great changes in the methods for the production and distribution of this form of energy; and with an unelastic system in which a corporation may have expended large sums of money the practical advantages of the introduction of electricity may be entirely dissipated for a long time. For the same reason it seems to the undersigned unadvisable at the present time for a corporation to adopt any style of plant which is adapted only to one system of distribution, however excellent the system may seem to be.

"They feel impelled to add one final word in view of the doubt that has been expressed as to the feasibility of constructing underground conduits for all purposes of electrical distribution. Certainly—at least, within the limits of large cities—whether or not it be found in the future to be desirable to enclose telephone and telegraph with light and power circuits, or any two of the foregoing in the same conduit, they express no opinion; but that the electric current for any and all of these purposes can be successfully transmitted underground there is not the least reason to question.

Digitized by Google

"They believe that a careful series of tests, made by competent experts on the systems already laid, would be of great value to science, and to all those who are interested in the use of the electric current."

We commend the information lately to hand concerning the distribution of electricity to those active and enterprising men who desire a change in the Electric Light Act. The alterations in this Act will depend very much upon the ability to show, not that installations of towns with ten, twenty, or a hundred thousand lamps have been rendered impossible, but that installations of one or two thousand lamps have been hindered by its clauses. The lighting of the Healtheries has been cited in proof of what can be done; but we consider it no proof at all. The conditions that hold at South Kensington are altogether different from those that hold in ordinary commercial transactions. The installation at Paddington will be watched with great interest, as it is really the second step in our experimental investigation of lighting on a fairly large scale, that at Holborn-viaduct being the first. There is one purely commercial question which should not in the present condition of things be overlooked. The putting down of a large installation, say 30,000 or 60,000 lamps, is even, after the Edisonian experience, a step in the dark. Ten years hence the capital required will be far less than at present, and investors of that period will have no sympathy with the pioneers who believed in the capabilities of existing systems. Then the pioneer companies will be overweighted with a capital account, and will see younger companies paying dividends due entirely to the experience gained by the operations of the pioneers. It is far better and far safer, from the commercial point of view, to go onward by gentle steps, from 500 to 1,000, from 1,000 to 2,000, than to attempt too large a task. Scientifically we have no doubt as to the ability to supply 50,000 or 100,000 lamps, but we are bound to work cautiously and protect ourselves from another wave of speculation.

CORRESPONDENCE.

LIFE OF INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With a view to obtaining the relations between the life of an incandescent lamp and the number of volts used, a question of so much importance as regards economy, I plotted out the numbers given in your issue of the 31st ult. as the results of experiments made at the Edison factory, Paris.

Taking the volts as abscissæ, and the hours as ordinates, the eleven resulting points were seen to lie well in a curve, and the curve on examination proved to be the logarithmic curve.

Let L = the life of the lamp in hours.
V = number of volts used.
L_0 V_0 = corresponding particular values of L, V;
we shall have

$$V_0 - V = k \log \frac{L}{L_0},$$

where k is some constant to be determined; V_0 and L_0 are together equivalent to one constant.

To find k from the present series of values, we have

$$V_0 - 95 = k \log 3595 - k \log L_0$$
$$V_0 - 96 = k \log 2751 - k \log L_0;$$

hence, by subtraction

$$1 = k (\log 3595 - \log 2751),$$
$$\therefore k = \frac{1}{\log 3595 - \log 2751} = 8{\cdot}60523.$$

Calculating in this way the values of k for the ten differences which we get between successive pairs of values of L, we find for the mean value $k = 9{\cdot}098213$, and the equation becomes

$$V_0 - V = 9{\cdot}098213 \log \frac{L}{L_0},$$

or giving to L_0 and V_0 the *normal* values of L and V, *i.e.*, 1,000 hours and 100 volts, we have

$$100 - V = 9{\cdot}098213 \log \frac{L}{1000}.$$

In the following table the values of L as deduced from this equation are compared with the values obtained by experiment:—

No. of volts.	Values of L obtained		Deviation.	Percentage deviation.
	From equation.	From experiment.		
95	3544·5	3595	+40·5	1·4
96	2752·0	2751	− 1	− ·04
97	2136·6	2135	− 1·6	− ·08
98	1658·9	1645	−13·9	− ·8
99	1287·9	1277	−10·9	− ·8
100	—	—	—	—
101	776·4	785	+ 8·6	+1·1
102	602·8	601	− 1·8	− ·3
103	468·0	477	+ 9	+1·9
104	363·4	375	+11·6	+3·2
105	282·1	284	+ 1·9	+ ·7

The deviations are not greater than one would expect.

The curve may easily be plotted out, if two pairs of values of L and V are known, by means of the following relation:—

If $V_1\ V_2\ V_3$ are in A P
$L_1\ L_2\ L_3$ are in G P

since the logarithms of numbers in G P are in A P.

Hence, if two points (1) and (2) on the curve are known, to determine a point (3) outside these, mark off

$$V_3 - V_2 = V_2 - V_1 \text{ and } L_3 = \frac{L_2^2}{L_1};$$

if (1) and (3) are known, to determine a point (2) between (1) and (3) mark off

$$V_2 = \frac{V_1 + V_3}{2} \text{ and } L_2 = \frac{L_1 + L_3}{2}.$$

In this way any number of points can be determined.—Yours, &c.,

F. M. WRIGHT.

12th February, 1885.

ANIMAL ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Ever since the time when a studious youth of the period decoyed a feline quadruped into the family coal cellar with the view of extracting chain lightning from its epidermis by a process of irritation which resulted somewhat prejudicially to the personal comfort of the operator, many individuals have devoted some consideration to the study of that branch of scientific research known as animal magnetism.

Other persons, whose absence of inclination or individual poverty in the matter of cats has led them to witness the *séances* of Mrs. Guppy, or the manifestations of "Ally" Slade, more or less vividly remember the cobwebbed maxim about the divorce between the unwise and their ready cash.

Despite, however, very many shattered superstitions, some people continue to throw a pinch of spilt salt over the left shoulder, or quake when a young man attired in a dress coat and a big gardenia extracts pins from the chairs on which they have been sitting. When a man whose duty, like that of the writer, has been to occupy the interregnum between attacks of coast fever by feeling the pulse of so many thousand miles of the long line which electrically connects the effete old world with the restless miasma pits of East Africa, a fraction of ex-

Digitized by Google

citement elevates itself to the importance of an integer, and one gets into the habit of alternating funereal compositions to the memory of the dead by more or less abstruse calculations as to the chances of the living.

The idea of testing a man's vitality by insulating and testing him for electrical quantity occurred during the relaxed and peaceful condition of the mind consequent upon the subsidence of an annual flood, which left everybody on the coast line without apprehension or uncertainty as to the question of a night's lodging. Then, with the view of cheering up my associates, I proposed to take electrical tests as to their several conditions, with the idea of ascertaining whether the theory that a high or low standard of physical power was consistent with the higher or lower degree of electrical force to be found in the organisation of my subjects. With the most perfect of registers at hand—the Thomson astatic galvanometer for delicate measurements—the certainty was assured that, with a perfectly insulated subject whose accumulated stock of electricity had been discharged by placing him in contact with the "earth," no mistake could be made in the tests taken by an experienced electrician. Taking first for my subject a colleague whose veins were throbbing rapidly with the premonitory symptoms of intermittent fever, I found the deflection of the galvanometer registered 320 divisions of the scale = ·2 milamperes. Then a subject offered himself who had been indulging, in near proximity of time, in more or less violent exercise. His registration approximated to the former test, but subsequently fell when his normal temperature was restored. Next, the registration of subjects enjoying robust health was ascertained, and could scarcely be distinguished from that of the persons whose vital current had been accelerated by the excitement of exercise or febrile disturbance. Against these results I took the debilitated and the Dutch.

The Hollander, whose blood flowed with the even and dignified pace of his beloved bullock waggon, gave no higher result than that of the individual whose vitality had been reduced by illness. These experiments were repeated again and again, under every imaginable condition, and the results have tallied.

From these facts I deduce the conclusion that the more rapid the circulation of the blood the greater the volume of electricity produced. The theory is, perhaps, not a new one; but those, at all events, who have experienced no difficulty in accepting the thought-reading hypothesis may accord me at least a moiety of support.—Yours, &c.,

A. S. T. E.

PERSONAL SAFETY AND ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Walker's involved and discursive questions are somewhat difficult to understand, and more so to answer. I can apprehend the meaning of four, more or less, which may, perhaps, be briefly dealt with as follows:—

1. I do *not* mean "that the body has the property of altering its resistance merely in obedience to the E.M.F. of the testing current without having undergone any previous physical change."

2. I *can* adduce "reason, beyond the bare fact that my measurements differ," for the statement I made, which is *not* the one given above.

3. On the several hundred "persons" observed by me, the resistance has invariably risen with "the continued application of a direct current." Mr. Walker, or "some parts" of him, may constitute an exception.

4. To the terrific hypothetical question about "some membrane, some organ, or some vessel," &c., and the effects on it of a "ridiculously small" current, I can only say I don't know.

Now for one line of fact as against pages of palaver. I have taken ten good congruous observations already on Mr. Mance's method. It works very well, and has, I believe, given me a firm basis for further research. I have submitted my first rough experiments to Mr. Mance himself, who has corrected and commented on them. The figures are singularly close to those originally obtained with momentary contacts and reversed current. Like these also, they are considerably larger than the results given with Kohlrausch's induction-bridge. I still believe, and can prove, that an imperfect conductor, like the human body, is more permeable to high tension than to low tension currents; indeed, the same is true of a wetted string. But another cause of error may still have been overlooked, in the unequal strength of induced currents at making and breaking contact. If the latter be considerably the stronger, it will not simply cancel the polarisation of the former, but leave a residuum of its own outstanding, which may easily produce a spurious lowering of apparent resistance. As soon as two cases occur which for therapeutic purposes need the "Faradic" or "continuous" currents in force, I will take the opportunity of charging both one and the other for a fixed time, and discharging through a good galvanometer.

Till then I shall not occupy your space further.—Yours, &c.,

W. H. STONE.

THE DAVEY MOTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Replying to the letter of your correspondent "Phœnix," I would explain that the ¼in. pipes are made to connect the motor with the coil, one (the supply pipe) connecting the steam space of the motor with the top of the coil, and the other (the return pipe) connecting the bottom of the coil with the air pump of the motor. The return pipe is throttled when it enters the air pump, to prevent waste of steam, as the only object of the return pipe is to take away the water formed by condensation of steam in the coil. The coil consists of 1in. vertical pipes, presenting about 20 square feet of surface.

It is obvious that the steam would not reach the coil if it were not for the return pipe and its connection with the air pump.

I find the ¼in. pipe is more than sufficient for the coil; but if I had several coils I should use a pipe of sufficient size for them.

I have had considerable experience in warming by means of steam and hot water, but I prefer steam, because with it smaller pipes may be used.—Yours, &c.,

HENRY DAVEY.

Rupert Lodge, Headingley, Leeds,
February 17, 1885.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to your correspondent "Phœnix," the Davey motor has been illustrated and described recently in *The Engineer*, *Engineering*, *Iron*, *Le Mouvement Industriel*, *The Mining Journal*, &c. With regard to the warming of the house, Mr. Davey has kindly informed me that he takes a lead pipe ¼in. in diameter from the steam space in the motor to a coil placed in the centre of his hall, and that a return pipe of the same diameter leads from the coil to the air pump of the motor, by which means he draws away the water produced by the condensation of steam in the coil.

I am safe in assuming that the ¼in. pipe working under the conditions named will convey 6lb. of steam at 212deg. per hour from the motor to the coil; and if the condensing surface of the coil were sufficient to condense that steam, 4,000 units of heat per hour, a quantity sufficient to raise over 40,000 cubic feet of air per hour 8deg. F., would have been thrown off from the coil in the house.

I have assumed 6lb. of steam only. It is evident that the quantity of steam delivered into the coil would vary with the difference of pressure in the coil, and in the motor boiler, and as that difference might well be from 4lb. to 6lb. per square inch, no doubt a much larger quantity might be delivered.

I do not wish to argue that a ¼in. pipe is necessary in every case; but I do most emphatically state that in this case it is amply large enough.

I may add that Mr. Davey informs me he has found it necessary to throttle the return pipe by reducing the diameter at one point, because the ¼in. pipe passed more steam than the

Digitized by Google

coil could condense. The radiating surface of the coil is 20 square feet.—Yours, &c., A YOUNG ENGINEER.

DR. DAVY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was very sorry to see in your last issue an announcement of the death of Dr. Davy, whose claims as pioneer in the invention of the electric telegraph are so conclusively proved in the pages of Mr. J. J. Fahie's recent work on the "History of the Electric Telegraph." It is to be regretted that the efforts of this early investigator in the domain of science should have remained hidden so many years, and it is the more so that just at the moment when honours *were* being conferred on him, his long and useful life should come suddenly to a close.

As a Member of the Society of Telegraph Engineers and Electricians I would venture to suggest that it would be only a matter of courtesy for the Society in some way to recognise the energy displayed by Mr. Fahie in unearthing Dr. Davy's early inventions, and proving his title to be classed alongside —if not in advance of—Cooke and Wheatstone.—Yours, &c.,

February, 1885. OBSERVER.

ELECTRICITY DEVELOPED BY CONTACT OF SIMILAR METALS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I remarked in my letter of the 2nd that my experiments might not be new. Since then I have observed the following phenomena:—On moistening two silver plates with saliva and putting them in contact a deflection of galvanometer needle ensued to the right, on moistening them with distilled water a deflection took place to the left, zinc plates with water a deflection to the left, with dilute sulphuric acid a deflection to the right, with methylated spirits to the left, iron plates with water a deflection to the right, with saliva deflection to the left.

I should be obliged if any reader can give some information on the subject.—Yours, &c., W. A. RUDGE.

Holyrood-place, Plymouth.

SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.

The following is a copy of resolution to be forwarded to the President of the Board of Trade, in accordance with the decision of the council upon a first report of the committee as announced at the meeting, Feb. 12, 1885:—

"That the Society of Telegraph Engineers and Electricians have seen with regret that since the passing of the Electric Lighting Act of 1882 public lighting by electricity has not made that advance in this country which was confidently anticipated, and hence there has not been that stimulus to progress in many of the branches of electrical science which might have been expected judging from the history of submarine telegraphs.

"That the society, having had the matter under careful consideration, have come to the conclusion that the restrictions in the said Electric Lighting Act have in a great measure contributed to check the advance of public lighting by electricity, and they venture to request the President of the Board of Trade to consider whether the said restrictions may not be modified or removed."

Electrotyping with a Dynamo Machine.

The first paper was on "Electrotyping with a Dynamo," by Captain H. R. Sankey, R.E. After referring to the work and requirements of the Ordnance Survey, the author pointed out that the electrotyping as practised was subject to the following conditions:—

1. The deposited copper must be homogeneous, without grit, as hard as possible, and capable of withstanding the pressure in the press.
2. Thick deposits are required, and in the case of duplicates the deposits must be of uniform thickness.
3. The surface to be deposited upon is large, but does not greatly vary.

The experiments described were carried out with an Elmore dynamo.

It is known that the quality and texture of deposited copper depends on the rate of deposition, or, in other words, on the density of the current, and that, if the deposition be very slow, the resulting copper will be hard and brittle; but, on the other hand, if the deposition be rapid, the copper becomes granular and wanting in cohesion. It is also clear that if thick homogeneous deposits are required, the rate should not vary to any appreciable extent during the deposition. Therefore, to fulfil our requirements,

1. The density of the current must lie between certain limits.
2. The current must be kept constant during the deposition.

As regards the first condition, no published information could be obtained at the time (lately some few results by Mr. Sprague have been found). It was therefore decided to measure the current flowing in our existing baths; this was effected by means of one of Cardew's ammeters, and it was found that in different baths the current varied from 23·4 to 26·4 amperes on plates of 7·7 square feet surface. As a check, a small plate $\frac{1}{8}$ square foot was prepared, and copper deposited upon it by means of a current of 1-5 ampere, being at the same rate as 27·7 amperes on the large plates. The resulting copper was, to all appearances, the same as that deposited in the large baths. Again, rather more than 1½lb. of copper is deposited on an average in 24 hours in each bath, which corresponds to a current of 24 amperes. It was therefore decided to so regulate matters that the dynamo would send a current of 30 amperes through each bath.

To fulfil the second condition of keeping the current constant, a very steady high-speed engine, regulated by a very sensitive electrical governor, is clearly the desideratum. After an inspection of most of the principal high-speed engines now manufactured, and careful consideration, Willans' high speed six-cylinder compound expansive engine was selected as being the best suited to our experiments. Mr. Willans had also just patented an electrical governor, and the engine was accordingly provided with one of these. It is not proposed to describe this governor, as Mr. Willans is about to read a paper on the subject before the Institution of Civil Engineers. Both the engine and the governor have been found to work admirably, and have fulfilled all expectations. The governor is exceedingly sensitive, and yet does not flutter; it is, in fact, dead-beat.

The next point for consideration was whether the depositing baths should be arranged in parallel, series, or combined parallel and series.

The more usual arrangement of placing the baths in parallel did not appear to be suitable, owing to the great difficulty, if not practical impossibility, of regulating the current in each bath with that accuracy required for our work, because the baths have not quite the same resistance, and more especially because the resistance of any particular bath is not constant; so that, even if the main current were regulated, the current in any particular bath would vary. Moreover, this arrangement was adopted by Messrs. Elmore in their experiment with 10 plates, and, as already mentioned, the result was unsuccessful.

The combined arrangement is open to the same objection, though perhaps not to the same extent. As far, therefore, as the regulation of the current is concerned, it is preferable to place the baths in series; and it may be added that this arrangement was recommended by Mr. Willans when the question of winding the solenoid of the governor was discussed. It is also to be noticed that incidentally the advantages of being able to place the baths at a greater distance from the dynamo, of using smaller leads, and of having less difficulty in making connections, are gained by placing the baths in series. Accordingly it was decided to adopt this arrangement if the dynamo would admit. It was therefore necessary to ascertain—

1. How many baths would be required.
2. What electromotive force is necessary to produce a current of 30 amperes through this number of baths placed in series.
3. Whether the dynamo could be altered so as to produce this electromotive force and 30 amperes.

To calculate the number of baths required, it is considered that the total output should be 120lbs. per week, and as the dynamo will work about 44 hours per week, it follows that*

$$x \times \frac{30 \times 44}{372} = 120,$$

or

$$x = 33 \text{ baths.}$$

The resistance of the bath with plates 7·7 square feet areas and ¾in. apart was found to be 0·0087 ohm (average).

It appears that each bath requires an electromotive force of

$$30 \times 0{\cdot}0087 + 0{\cdot}016 = 0{\cdot}276 \text{ volt;}$$

so that the total electromotive force required is

$$33 \times 0{\cdot}276 = 9{\cdot}1 \text{ volts,}$$

or, say, 10 volts to allow for leads and connections.

Before mentioning the experiments carried out to ascertain whether the dynamo could be altered so as to give 10 volts and 30 amperes, it will be as well to describe the dynamo and the apparatus used for measuring the current and the electromotive force of the dynamo. The dynamo has somewhat the appearance of an alternate current machine; its armature consists of a disc of cast iron 1ft. 6in. diameter, on each side of which are fixed 10 coils wound with 7 B.W.G copper wire, and having each a resistance of 0·00297 ohm. As originally arranged, one set of the commutator segments (alternate segments) were connected to two rings, one on each side of the armature disc, but insulated from it; to these rings one end of each armature coil was connected, the other end being connected to the armature disc, which in its turn is connected to the remaining segments of the commutator. It will thus be seen that, as originally arranged, the armature coils were in parallel, so that the resistance of the armature was very low; in fact it appears by calculation to be 0·000149 ohm; and further, that the electromotive force must be very low, being that induced in one coil. The field-magnet coils are similar to the arma-

* $\frac{\text{Current}}{372}$ = weight of copper in lbs. is a convenient formula derived from electro-chemical equivalent of copper.

REMARKS.—The engine was worked compound for all experiments except No. 33, when it was worked simple. An additional resistance of 0·85 was placed in field magnet circuit.

ture coils, but larger, wound with the same sized wire, and each coil has a resistance of 0·0347 ohm. These coils are fixed to the cast-iron sides of the dynamo, and the armature revolves between them. The poles on each side are alternately north and south, and a north pole of one side faces a south pole of the other side. As originally arranged, the field coils were connected in combined parallel and series—that is, each two consecutive coils formed a pair connected in series, and these pairs, ten in number, were placed in parallel; the resistance of the field was therefore 2-10ths 0·0347 = 0·0969 ohm.

The armature, fields, and circuit were placed in series.

It will be observed, since the ends of the various coils can easily be got at, that by joining in series, or in combined series and parallel, the electromotive force of the dynamo can be increased up to a certain amount. It is also possible to arrange the fields in shunt with the circuit. The commutator is not merely a collector, as in most dynamos, but actually commutes the current; consequently the brushes can be arranged in different positions on the commutator so long as they bear on alternate segments. Should they, however, be displaced, so that even for an instant they bear on the same set of segments, they will begin to flare, and the current in the circuit will be considerably reduced. The same result will occur if the points of one or both brushes are not placed exactly parallel to the segments. A very small deviation from the true position of the brushes is quite sufficient to prevent any current being developed. In consequence, the adjustment of the brushes has been and is still the greatest difficulty. At first they had to be adjusted continually, and not the least dependence could be placed upon them. By altering the brush-holders and making them more substantial, better results have been obtained, but still very far from perfection.

Careful measurements were made with a Cardew current meter, a potentiometer, and a Wheatstone bridge, with results as described below.

The first experiments were made without altering the original arrangement of the dynamo, but it was found, as for that matter was expected, that the resistance of the leads and connections (namely, 0·057 ohm) was too great, and only a very small current was developed, which was, however, not measured.

The armature and field coils were then placed in series, when it was found that a current of about 100 amperes was developed through an external resistance of about 1 ohm at 600 revolutions.

The following arrangements were then successively tried:—

a. Amature, fields, and circuit in series.
  (1) Armature—two sets of ten coils in series, the two sets being in parallel. Fields in series.
  (2) Armature as in (1). Fields—two sets of ten coils in series, the two sets being in parallel.

b. Fields placed as a shunt to circuit.
  (1) Armature in series.
  (2) Armature—two sets of ten coils in series, the two sets being in parallel.

The last arrangement was found to be the most suitable for our purpose, as, in the first place, the desired electromotive force and current can be obtained at a low speed, as will be seen by reference to Table A; and, secondly, by means of an alterable resistance placed in the circuit of the field-magnets the current and the speed of the dynamo can be kept constant whilst the resistance in circuit is altered, so that the number of baths in the circuit can be altered to suit our daily requirements without altering to any great extent the speed of the dynamo. This arrangement was therefore adopted, and a coiled iron wire resistance was made which allows of 1·2 ohm being introduced into the field-magnet circuit, proceeding by 0·06 ohm. As thus arranged, the resistance of the armature is 0·0297 ohm, and that of the field-magnet coils 0·684 ohm. It is therefore evident that, so far as the dynamo is concerned, there is no reason why the baths should not be placed in series. Accordingly arrangements were made to wind the solenoid of the governor so that the whole current of about 30 amperes would pass through it, the solenoid being placed in series with the baths. This was effected by winding the coil in two halves placed in parallel, the total resistance being 0·01 ohm, or rather more than that of one bath. The governor was then fixed and adjusted by screwing up the spring until the ammeter showed a current of 30 amperes (nearly). As already mentioned, this governor has been found to answer admirably. At first the spring slackened slightly, and so reduced the current, but as soon as it had taken a set the current remained perfectly constant, with the exception of occasional rapid variations of small amplitude due to defects in the brushes. Before beginning to deposit, it was necessary to ascertain which terminal of the dynamo should be connected to the receiving-plate. This information was obtained by observing the direction of the deflection caused by the dynamo on a galvanometer placed in a shunt-circuit, and comparing with the deflection produced on the same galvanometer by an ordinary cell.

A condemned plate was now placed in one of our ordinary horizontal baths and was deposited upon for 31¾ hours, the place of the remaining baths being taken by the coiled iron wire resistance above referred to. The deposited copper was removed, and found to be of excellent quality. The weight deposited was 1,076 grammes, which corresponds to 28·7 amperes, using the latest determination of the electro-chemical equivalent of copper by Lord Rayleigh, viz., 0·003281. According to Cardew's galvanometer, the current during the deposition was 29·2 amperes.

It was observed that the back of the deposited copper was finer in grain than that deposited at the same rate by the Smee cells. It was thought that this apparent contradiction to the law that the quality of the copper depends on the rate of deposition could be accounted for on the supposition that the current from the Smee cells is variable, and this supposition is born out by the fact that numerous bubbles of hydrogen are continually rising in these cells, but not by any means at a uniform rate, so that it appeared probable that the internal resistance and even the electromotive force are continually varying. It was therefore surmised that deposits suitable for our purpose might be obtained with the dynamo, using a greater current strength than 30 amperes. To test this, the condemned plate above referred to was reduced in size so as to increase the density of the current, and the results obtained were as follow (the governor was re-adjusted and the current increased to 30·5 amperes):—

Size of plate. Sq. ft.	Current per sq. ft.	Corresponding current on plates 2′ 4″ × 3′ 4″.	Resulting copper.
5	6·1	47·0	Good.
4	7·6	58·5	Good.
2·8	10·0	77·0	Good, rather rough at the edges.

Taking, therefore, the 2′ 4″ × 3′ 4″ plates as a standard, it appears that the current can be increased to at least 50 amperes.

Since the above was written, some experiments have been made to ascertain whether there is any variation in the current from the Smee cells, but no appreciable oscillation in the current or in the electromotive force could be detected, only a gradual and very slight diminution. This matter, therefore, appears to require further research. These deposits were made in a *vertical* bath. In the first experiment (on the plate of 5 square feet) the solution was intentionally allowed to remain undisturbed. The resistance gradually increased, but the governor kept the current constant until the throttle-valve was completely open, when of course the current began to fall off.

An india rubber tube was now inserted in the bath, and air blown in by means of a small foot bellows. The large bubbles of air in rising displaced

Digitized by Google

the solution, and very soon equalised its intensity. It is therefore hoped that it will be possible to use vertical baths, at any rate for matrices, the advantages gained being simplicity in construction and less space occupied than with horizontal baths.

Whilst the above experiments were being carried out, a matrix was laid down in one of the horizontal baths, with the intention of producing a duplicate sufficiently thick to print from. This intention was, however, not carried out, as it was found that without doubt the dynamo could produce as good copper as the batteries; and on the 10th December, 1844, Colonel Stotherd, R.E., Director-General of the Ordnance Survey, authorised the batteries being replaced by the dynamo. The experiments were thus brought to a close, and preparations are now being made for the contemplated change.

At the conclusion of Captain Sankey's paper, a number of gentlemen joined in complimenting him upon the usefulnes and novelty of many of the practical details he had described; and an opinion was expressed that similar operations may now be rendered possible on a much larger scale.

Mr. J. A. TIMMIS then read a paper on "The Working of Railway Signals and Points by Eletro-Magnets," the substance of which, however, had been delivered at the Institute of Mechanical Engineers last November, and appeared in *The Electrician* on the 8th of that month. The discussion on this paper was adjourned until 26th inst.

PHILADELPHIA EXHIBITION.

The following reports of the examinations on underground conduits have just been issued by the Franklin Institute. We have not thought it necessary to engrave all the illustrations, as many of them are merely catalogue pictures, and show nothing of the principles adopted :—

THE AMERICAN SECTIONAL UNDERGROUND COMPANY.

("A. b." of Section's Classification.)

This system consists of cast-iron conduits, built up in sections breaking joints, the joints being secured with clamps and keys and cement or other packing. All parts of each particular size are interchangeable. The conduit contains interchangeable metallic shelves and partitions, dividing it into compartments for carrying wires of different kinds. Three sizes of conduit were exhibited, each being connected to a manhole placed at every street corner, into which one or more men can enter for the purpose of hauling in the wires, making the necessary connections, &c. There are further, at convenient distances along the line of conduit, handholes for tapping the wires for house-to-house supply. As the position of these is accurately known, by opening up a few stones in the pavement a wire or wires can be tapped for house supply. This is effected by running the wires required from the nearest manhole on the upper or local shelves. Different companies can be supplied with separate compartments, and they can employ any particular insulation they prefer.

It is claimed for this system that "a metallic contact between the insulation of all wires and the earth grounds all leaking or induced currents, overcomes induction to a great extent, and renders harmless a cross in an electric light current. Further, that by the use of the copper shelves, in conjunction with telephones on metallic circuits, there is absolutely no interference whatever." The committee was unable to satisfy itself on all these points. The conduit when opened appeared to be very dry. It is stated that all condensation of moisture in the conduit takes place only under the manhole covers, which are exposed to the external air. This seems to be borne out by observations on the 9th of October, 1884, no rust being visible. This system seems to meet, in a very complete way, the question of house-to-house supply, separation of wires, facility of laying, repairs, and future expansion. It is not necessary to lay the wires in the conduit until absolutely required. It would, however, be necessary to use first-class insulated wires, as it would not be possible to keep such a conduit absolutely dry. Some provision will also have to be made for passing off gas, which tends to accumulate in the main, and might be set on fire and prove dangerous. It is estimated that the A conduit, 10in. by 15in., would cost 15,000dols. per mile, the B conduit, 6in. by 10in., 10,000dols., and the C conduit, 5in. by 8in., 5,000dols. The A size of conduit, which is laid in Chestnut-street, Philadelphia, from Third to Broad (equivalent to Fourteenth) streets—(about a mile in length)—is estimated to accommodate 3,000 wires. The B size is laid in Tenth, Eleventh, and Brown streets, and its capacity is for about 1,200 wires. By means of the large manholes and separate compartments the wires in use can be at any time taken out, replaced by others, or inspected and put back, in the shortest time and with no derangement to the pavements and streets. The size of the conduit also enables one to lay a very large number of wires. The prevention of induction would seem to be about equal to that in all systems employing iron-cased ducts, with the additional advantage of interior metallic screws and copper shelves, all well grounded, so that no current in one compartment would be likely to have any influence on those of another.

The conduits were laid down along Chestnut-street in October, 1883, and the electric light service has been continuous since the latter part of December of that year, which period included a number of severe storms, of longer or shorter duration. It has not been ascertained that any interference with the service has been suffered. The weather during the continuance of the exhibition was unusually dry, and therefore, though the interior of the conduits was dry wherever seen by the examiners, this would not establish the fact of the successful exclusion of moisture by this system under unfavourable circumstances. On this point the undersigned have been compelled to take the testimony of the officers of the company and the statements of the subscribers as to the success of the conduits for the electric light wires. Few, if any, telegraph or telephone wires were in the conduits, and as it is with these that the defects of any system would be best observed, the examiners have no sufficient data for expressing an opinion. It is the intention to introduce these insulated telegraph and telephone wires loosely, or without any casing, unless there be a long distance in which no service is ever to be made. Under these circumstances the company proposes to use a cable. Otherwise, the wires are to be laid loosely over each other in their various compartments.

A question which is intimately connected with the conduit itself is that relating to the exclusion from it of foreign matter, and especially of water. [The company has suffered from gas in its conduits, and on one occasion an explosion ensued in a manhole near the State House, but this latter caused no serious damage, and it is not thought likely that there are many localities where these conditions of gas waste under the streets are likely to be similar.]* In the streets of a city where there were great differences of level, any considerable break in the conduits which would permit the influx of a large body of water might (if the latter found free path) do considerable damage. This is an objection applicable to all hollow conduit systems. Open gratings have been employed to permit the waste gas to dissipate itself, and these gratings have often remained open during both snow and rain storms without introducing moisture into the main conduits, the water escaping by a trap at the bottom of the manhole. So far as the renters of the light are concerned there is not the least danger of the introduction into their houses of water or gas from this company's conduit, inasmuch as the electrodes are hermetically sealed in a gas pipe which leads them from the handhole. A telephone wire is laid down in the conduits, leading from the company's central office, in Eleventh-street, to Broad and Chestnut-streets corner. This was tested in the daytime, when the electric light currents were not passing. The terminal instruments were also out of order. The committee cannot, therefore, say what may be the effect of the electric light current on the telephone lines from this observation.

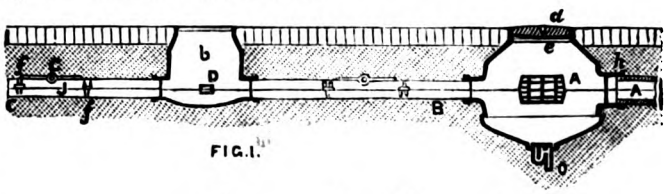

FIG. 1.

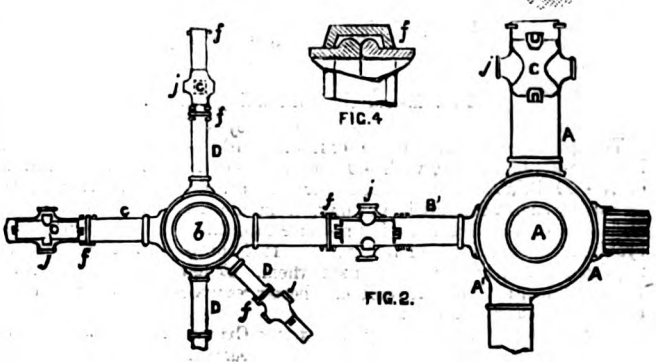

FIG. 2.

FIG. 4.

The following is a description of the figures in the cut :—

Fig. 1 represents a longitudinal elevation of various sizes of conduit A, B, C, with vertical sections through "manhole," *d*, *e*, *g*, and "flush box," *b*, showing mode of laying and connecting them.

Fig. 2, plan view of same.

Fig. 3 (not shown) is an isometrical view of section of A, conduit, and handhole, *c*, *j*, showing joints of upper and lower sections of conduit, K, K, partitions and shelves for electric wires, the "static condensing shelves" being shown by dotted lines.

Fig. 4, transverse section through top of clamp, showing section of ends of conduit and packing at joints. The letters show similar parts in the different figures, A being the largest size conduit yet made, capacity about 3,000 wires. A', showing the conduit opening in manhole when connection is made at one side of manhole or flush box. B, C, and D are consecutively smaller sizes of conduit; *a* manhole, *b* flush box, *c* handhole, *d* manhole and flush box cover made either solid or perforated for ventilation; *e*, bar with which to fasten cover by aid of bolt and nut; *f*, clamp and keys by which the different sections of the conduit are connected; *g*, trap for drainage of any water which may collect in the manholes and flush boxes from rain or condensation, and which may be connected with sewer; *h*, street bed, earth and gravel; *i*, street paving; *j*, handhole opening for house connections; *k*, longitudinal joints between upper and lower sections of conduit, to be filled with any suitable packing to exclude moisture, &c.

THE ANDERSON CONDUIT FOR UNDERGROUND WIRES.†

("C" of Section's Classification.)

This conduit is constructed of cellular section and of any suitable material, such as iron, terra cotta, or glass. It provides a series of ducts, into

* This report was completed on October 30th, 1884.

† Patent No. 261,979, dated August 1st, 1882.

Digitized by Google

which cables or wires of different classes or belonging to different subscribers, may be accommodated. In both sides of the conduit are a series of lateral openings, formed in the process of manufacture of each length of the conduit. These openings give access to the ducts on either side, and are intended for tapping the wires at any desired point. Each side duct, on either side of the conduit, has one of these lateral openings, which are not arranged one over the other, but diagonally and in adverse directions on either side. The object of this arrangement, which appears to be the main feature of the system, is to obviate the weakening of the structure, which would result from having a row of openings one above the other. No provision is made for manholes, and no arrangements are proposed for obviating the effects of induction, nor for keeping the duct water tight or free from condensation. The description and model were not sufficiently complete to enable the committee to form any opinion of the details, but the provision of a lateral opening to each side duct would have many disadvantages.

The Brooks Underground Conduit.

("*A. a.*" *of Section's Classification.*)

This conduit consists of wrought iron pipes, supplied with suitable splice boxes, handholes, and outlets. These pipes are protected from oxidation by being laid in a wooden trough, into which hot pitch is poured so as to completely envelope the pipe. The wires to be used in this system are covered with cotton and formed into a rope or bundle, which is then covered with a textile weaving. The bundle of wires is then soaked in hot mineral oil and drawn in long lengths into the pipe or conduit. A heavy mineral oil is then forced into the pipe so as to exclude moisture, and for the purpose of maintaining a good insulation.

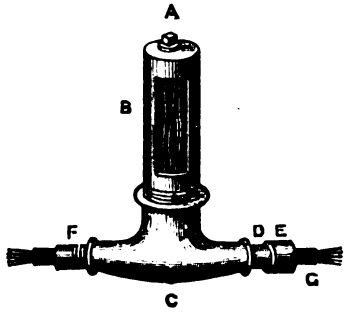

Fig. 1.—Method of Making Splices.

The patentee estimates the cost of laying a 2½in. pipe complete, for house-to-house supply, with 40 conductors of No. 16 B.W.G., and 360 of No. 20 B.W.G. at 20 dollars per mile per conductor. He states that he can lay such a conduit in one day, from block to block, so that its construction causes but little interference to traffic. The main point of the system is the economy of insulation. It is proposed to anticipate future requirements by laying down as many wires as may be required for a long time to come, and not to add or withdraw any. It is a system which seems better adapted for trunk or through lines than for house-to-house supply, owing to the difficulty that would be experienced with the overflow of oil at so many points. In towns where there was much difference of level the head of oil would doubtless be a source of great trouble.

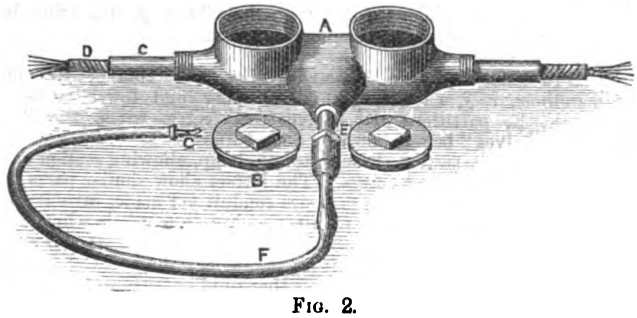

Fig. 2.

Fig. 2 shows the handholes and outlets for taking wires into adjoining buildings. F, is a piece of lead pipe, of any desired length, sufficient to reach the first story of the building in which the wires are to be extended or looped. The lead pipe F is filled with a heavy and viscid oil until it reaches within 2ft. of the point G, where it is spliced to india rubber or gutta percha covered wires. The space between the gutta percha covered wires and the lead tube is filled with plaster of Paris and silicate of soda, which effectually prevents any leakage of the oil.

Fig. 3 shows a splice-box, handhole and outlet on both sides, designed to accommodate 400 wires. C is a 2½in. diameter pipe. Reducing sockets can be introduced at B for a smaller pipe and less number of wires. These boxes are introduced at intervals, fastened with plug D, for bringing out the wires. The box is 7in. in diameter inside. When used for splicing the ends of the cable, dome F is screwed into the top of the box. G is a plug in the top of the dome for pouring in oil after the splice is made. On either side of this box is outlet E, similar to that shown in Fig. 2.

Fig. 4 shows the tank at the Pennsylvania R. R. Station, Broad-street, Philadelphia, supplying the system with pressure and the oil lost by leakage (which is not perceptible).

[Figs. 3 and 4 are not engraved as they will readily be understood from the description.]

As regards the efficacy of the oil, as a means of insulation, Mr. Brooks exhibited to the examiners this experiment:—Two wires were attached to the Holtz machine, the extremities being carried into a narrow jar of his insulating oil, in such a manner that while the distance between them was ¼in. in the oil, they were 1½in. apart at the surface of the oil. On turning the machine, the spark passed above the surface of the oil, and not at all through the oil, even when the distance between the extremities was reduced to 1-16in. A number of experiments were made as to the effect of the Brooks system in reducing induction and other disturbing elements; various circuits having been politely put at the examiners' disposition for this purpose in the Pennsylvania railroad building. One of these was a line through a Brooks conduit to the Broad-street Station, and a return through the earth. This line gave a considerable amount of disturbance, the noise being rather deep than loud, and reminding one of visible movement. The voice was carried clear and distinct. A second Brooks circuit was metallic, *i.e.*, the message went and returned by wire, the distance between the station being about 1¼ mile. The crackling noise was audible, but not loud or deep. A line to Merion Station and return, by overhead wire (14 miles), worked nearly as well. The crackling was *finer*, *i.e.*, shriller and more continuous, but not so disturbing. No means were available for testing the amount of interference with each other of the several wires of telegraphic and telephonic circuits in the same tube, worked simultaneously. 2,000ft. of wire are pulled through each length at a time.

(TO BE CONTINUED.)

THE DRAWBAUGH TELEPHONE CASE.

AMERICAN BELL TELEPHONE COMPANY AGAINST THE PEOPLE'S TELEPHONE COMPANY ET AL.

(CONTINUED FROM PAGE 280.)

The first group of facts of this nature are those which bear upon the capacity and character of Drawbaugh as an inventor, and tend to show that it is not only highly improbable but almost impossible that he could have been the author of the telephone.

In the summer of 1878 he composed a biography of himself for publication in the history of Cumberland County, which presents a graphic picture of the inventor and of the man. He commences by describing himself as "born in the quiet, secluded village of Milltown, three miles from Harrisburg," and as one of the greatest inventive geniuses of this age, who has spent the greater part of an active life conceiving and producing as the result of the conceptions of an unusually fertile brain a score of useful, ingenious machines and devices. It appears, he says, by examining a list of his inventions that the manufacturing interests of the place in his boyhood days gave direction to his thoughts and incentive to his actions. He proceeds to enumerate a list of his inventions as follows:—"His first invention was an automatic sawing machine; then a number of machines used in waggon making; then a machine for boring tenets; then a machine for sawing tenets; a barrel stave jointing machine, patented 1851. This machine was pretty generally introduced and its merits appreciated. An automatic grinding machine was next invented to meet a demand created by the introduction of the jointer; then followed several machines for making stave headings and shingles, all of which were patented in 1855; after which machines for rounding, heading, crozing, dressing and finishing outside of barrels were invented; these were again followed by device for running mill-stones, one for dressing mill-stones, a device for elevating grain in mills. He then invented and had patented four improvements in nail-plate feeding, next a tack machine and a new design in tacks. Photography next engaged his attention. He fitted himself for action in this field by manufacturing his own camera, ground and fitted achromatic lenses for camera, prepared the necessary chemicals and improved the process for enlarging pictures. Next electricity and electric machinery attracted his attention, and an electric machine was produced throwing out of consideration the galvanic battery and electric pile; then a machine for alphabetical telegraphing; then the justly celebrated electric clock and the machinery necessary for its construction; and several kinds of telephones, one of which is operated by battery and another by induction." He concludes as follows: "It will be seen from the foregoing that Mr. Drawbaugh has penetrated vast fields in search of information, and with what success we leave the reader to determine. We are proud to own Mr. D. as a citizen of our township, and deem him worthy of a position at the head of our prominent men, and are happy to accord him that position." This portrait, drawn by himself, depicts without the aid of extrinsic evidence the ignorance and vanity of the man, and the incongruous and fantastic assortment of his inventive projects. It suggests also the character of a charlatan.

That he was a skillful and ingenious mechanic is undoubtedly true. Invention was his hobby and his vocation, but that he was an inventor in the large sense is disproved by the nature and results of his work. Every patent that he obtained was for some improvement on existing devices which involved mechanical skill rather than any high degree of inventive faculty. This is shown to some extent on the face of his patents, the list of which is as follows:—

November 11, 1851, "for improvement in stave jointing machines;" May 22, 1855, "for stave machine;" April 28, 1864, "for improvement in mill stones;" May 12, 1863;" for improved machine for levelling the

Digitized by Google

faces of mill stone;" December 12, 1865, "for improvement in nail plate feeders;" November 20, 1866, "for improvement in faucets;" November 19, 1867, "for improvement in nail plate feeding device."

His own testimony, given in an interference proceeding in the patent office in 1869, shows that none of his inventions were sufficiently meritorious to prosper vigorously. That proceeding involved a question of priority of invention between himself and one Hauck, respecting an improvement in a faucet. He had filed his application for a patent in January, 1879, and undertook to carry back the date of his invention to 1869. The scope and range of his inventive faculty became a subject of inquiry. He there testified that he had made he might say fifty inventions and had patented over a dozen. He was cross-examined respecting certain inventions to show that they did not work satisfactorily. He was then asked: "Since 1866 what machines have you conceived and perfected that have worked satisfactorily?" He answered: "To the best of my knowledge I think they all have. The nail machine gave satisfaction. I had it running in the works, but the nailers drove it out. The tram and red-staff was a good machine, and adopted by a number of millers. The magnetic clock I consider a good thing, but I am not through with experiments on it yet. I believe this last faucet to be a good thing." If his nail machine had induced the workmen to drive it out of the shop it ought to have commended itself to the capitalist. His magnetic clock had not been patented at this time, though it had been for a time the wonder and admiration of the community in which he lived; but when it was patented in 1879, it was a "new article of manufacture," consisting of a galvanic battery for electrical clocks which had two old elements united instead of being disconnected as in former devices. The history of his clock shows clearly that it was of no practical merit; and the clock had been substantially described in "Tomlinson's Encyclopædia," and he had the book before he made his alleged invention. His other electrical devices he never patented, and in his testimony in the interference proceedings he did not refer to them as among his perfected and successful inventions. One of these was his magneto-electric machine for short line telegraphing and fire alarms, sometimes mentioned as his magneto key. It was not a new device, and the proofs shew that it was a failure.

When the speaking telephone was first introduced to the attention of the scientific public it was pronounced by one of the most eminent electricians of the day "a result of transcendent scientific interest" and "the greatest by far of all the marvels of the electric telegraph." The inventions attributed to Drawbaugh include not only the conception of the principle of the unbroken, undulatory electric current, and of the delicate and complex instrumentalities essential to its efficient application in transmitting and reproducing articulate speech, but also of many other devices involving a nice adjustment of forces and requiring sensitive mechanism. These were inventions of a peculiarly scientific order which would seem to demand a special conversance with the principles of acoustics and electricity. Besides making the cardinal discovery of the theory of the unbroken undulatory current, Drawbaugh is assumed to have perfected a brilliant and extraordinary series of original discoveries for which, to use the words of Mr. Benjamin, "there is no parallel instance in the whole history of invention." Mr. Benjamin, referring to the microphone which was introduced to the public in 1878, by Mr. Blake, but which is one of the instruments asserted to have been invented by Drawbaugh at an earlier date, says, "It was looked upon as a great and original discovery."

It was said by Chief Justice Taney (O'Reilly *v.* Morse, 15 How., III.), speaking of the invention of the telegraph, "No invention can possibly be made consisting of a combination of different elements of power without a thorough knowledge of the property of each, and the mode in which they operate on each other. For no man ever made such an invention without having first obtained this information, unless it was discovered by some fortunate accident." None of Drawbaugh's alleged discoveries were made by accident. His statement is that, starting with the belief that speech could be transmitted by electricity, he made first one contrivance and then another, gradually obviating difficulties and making advances experimentally, until he finally perfected the several inventions.

In view of Bell's special equipment for investigation and experiment in electrical and acoustic science, it would not seem strange that his persistent efforts tried to effect the electrical transmission of speech were eventually successful were it not that others as intelligent, as well equipped, as ingenious and as persevering as he, had devoted years to the same object in vain. He had the assistance of Mr. Watson, an expert in electricity and a skilled workman in electrical mechanism, in constructing the apparatus employed in his experiments, and who also aided him in his experiments. He had demonstrated his inventive proficiency by inventions in telegraphy for which patents were granted to him. And yet had it not been for an accidental discovery made by him in June, 1875, and which would probably have escaped one whose trained faculties were not centred on a careful study of the phenomena, he might have failed.

Drawbaugh, on the other hand, was not only untutored, but he was isolated by his associations and occupations from contact with men of advanced science; he had narrow opportunities for instruction, and few incentives for profound research. Among the multitude of his inventive conceptions was one that a talking machine was a possibility. According to the testimony of Lory, a witness for defendants, before Drawbaugh began his practical experiments he exhibited a sketch of a machine that he was about to make that would talk a distance of twenty miles and work something like a telegraph. If this is true he commenced on his telephone as the architect plans a building or the engineer makes a draught of his structure. His own testimony shows that he did not attempt to qualify himself for electrical inventions by any systematic study after he began experimenting with his talking machine. Although he had undoubtedly acquired considerable desultory information about electricity, and especially about the mode of operation and detail of construction of electrical mechanism, it is obvious that when he commenced with his talking machine he was a tyro in electrical science, essaying the most difficult work of the electrician.

(TO BE CONTINUED.)

LEGAL.

UNITED TELEGRAPH COMPANY V. SHARPLES.

This was an action brought by the United Telephone Company, in the Chancery Division, against Mr. George Sharples, an electrical agent, dealer, and manufacturer, of Preston, for an infringement of the electrical patents of Bell and Edison. Mr. Aston, Q.C., with whom was Mr. Moulton, explained that the defendant had obtained for exportation telephone apparatus from a firm called the "American Telephone Company," Rotterdam; but he had tested such apparatus here, and retained sample machines, which he submitted was a user in this country, and consequently an infringement of the plaintiffs' patent. Defendant had further infringed the patent by offering for sale all the component parts of Bell's and Edison's telephone, which constituted, when put together, the complete apparatus, and had also committed an infringement by having had made for him Hinckley's and Crossley's receivers. Taking all these circumstances together, he asked his lordship to grant an injunction.—Witnesses, called in support of plaintiffs' case, showed that the company sold the machine under special conditions to railway companies, but lent them out to customers on payment of royalty.—On behalf of the defendant, Mr. Hastings, Q.C., with whom was Mr. Goodeve, submitted that, as to the machines imported from Holland, the defendant had acted in a perfectly lawful manner, because the machines had been imported for experiment, so that there was no user for profit, which was a necessary element in an infringement. No user had been proved; and, as a matter of fact, the infringing instruments had not been used at all.—Mr. Sharples, the defendant's son, stated that he first heard of the machines complained of from a Mr. Bateson, who represented that they might be useful for experimental purposes, and he wrote the letter ordering some of them, as the cost was small, but none of the machines had been sent to customers abroad; and as soon as this action was commenced the machines were given away and exported. Evidence was also given to the effect that the instruments sent to the defendant at Preston by the Rotterdam Company were for experiment and for teaching his pupils their business; that the machines were not exported abroad until after the commencement of the action, when they were presented to Messrs. Berline, of Manchester, who have a house at Moscow, the instruments being sent to the latter place by the advice of defendant's solicitor. Defendant's counsel having summed up the evidence, Mr. Justice Kay, without calling on plaintiffs' counsel, gave judgment. He said the balance of evidence was in favour of the plaintiffs' theory, and he therefore held there was clearly an infringement; while the mode in which it was done, and the mode in which it was now sought to defend what was done, called for his strongest reprobation. He ordered that there be a perpetual injunction against the defendant Sharples, restraining him, his workmen, and agents from infringing the patents included in the plea of the plaintiff company, ordering him to pay all the costs. With reference to this case, the company's solicitors have written to the *Standard* to the effect that, contrary to that paper's statement, that the judge held there had been no user, and had dismissed the action, with costs, his lordship, after commenting somewhat forcibly on the evidence given in the witness box by the defendant's witnesses, granted a perpetual injunction, with costs against the Defendant.

COMPANIES' MEETINGS & REPORTS.

The Submarine Telegraph Company.

The half-yearly ordinary general meeting of the proprietors in this Company was held at the Company's offices, 2, Throgmorton-avenue, on Tuesday last, Sir Julian Goldsmid, Bart., presiding.

The SECRETARY (Mr. S. M. Clare) having read the notice calling the meeting, the Company's seal was affixed to the register of shareholders. The Directors' report and statement of accounts were taken as read.

The CHAIRMAN then said: Gentlemen, in moving the adoption of this report, there are a few matters in it with regard to which I have to make some observations on behalf of the Board. You will observe that the receipts are somewhat less than they were in the corresponding period of 1883. Well, that is accounted for in various ways; but principally by the fact to which I have referred on several previous occasions, and which is also alluded to in the report, that a condensation of messages has been going on for some years past, and appears still to continue. There are some curious observations to be made with regard to this circumstance. For the half year up to December, 1883, the number of messages was 1,396,634; up to the June half of 1884 it was 1,377,419—a smaller number of messages, you will observe: and up to the December half of the same year it was 1,428,520, a larger number of messages than for either of the two previous half years. But, nevertheless, the largest number of words was in the half year ending December, 1883, namely, 17,226,788 words; while in June, 1884, the number was 16,583,147, and in December of the same year 17,007,776; so that actually we got in December, 1883, nearly 32,000 messages less, whereas we had then over 200,000 more words transmitted. That shows you, therefore, the reason why our receipts are less. Or, to put it in another form, the average number of words per message in 1883 was 12·33; in June, 1884, it was 12·04; and in December, 1884, it was 11·91.

Digitized by Google

Therefore, you have to compare 11·91 with 12·33, showing the average length of messages, to arrive at the main explanation of the difference in receipts. Mr. Clare has been good enough to show me many facts with regard to this difference in our returns, and there is one very curious circumstance that I have not mentioned before, which it may interest the proprietors to know, to whom we are always glad to give information on these matters. It appears, as you will see by the figures that I am about to give, that the average length of messages in the winter months is less than it is in the summer months. In January of last year the average length was 11·92; in February, 11·99; in March, 12·14; in April, 12·07; in May, 12·08; in June, 12·02; in July, 12·07; in August, 12·16; in September, 12·02; in October, 11·70; in November, 11·62; and in December, 11·89. Consequently, when I look at these figures, I find that the highest average is in August, and the lowest is in November, and that the summer months are better than the winter. What the reason is I cannot say. It may be that there is more public business going on when Parliament is sitting, or there may be other reasons to account for it. There is the fact, however, and I desire to put that before the proprietors. That practically shows the small items of differences, and that is the main point to which I have to refer. On the other side, you will observe that there is a considerable increase in expenditure, and of course the shareholders, like the Board, are anxious to know the reason of this increase. There are several items which will explain it almost immediately. One is that the salaries of the French clerks—that is to say of the clerks that are employed on the stations in France, which are by our concession fixed by the French Government—have been increased by the French Government, and therefore all that we have to do is to pay, and that being so, we have had to pay £270 9s. 6d. more on that account. There is another point with regard to the French Government to which I will refer immediately. Then, according to the arrangements under which our clerks have come into our service, and many of our general *employés*, there is a gradual scale of rise which was settled some years ago. The system has been adopted generally by telegraph companies, and is the only one that is found to work satisfactorily, and the result has been that a considerable number of clerks have risen into the higher scale. This has increased our payment by £992—which includes the £270 additional paid by the French Government—so that we have increased under that head a little over £700. In addition to that there has been a small increase in the repairs to premises, a small one in rates and taxes which we cannot alter, and an increase of £465 in the repairs to cables. That increase of £465 was owing to the necessity of putting a very considerable length into the Dieppe cable. I believe that the cables are in capital order, and it is of very great advantage to us that the new cable between Holland and England has been laid down by the Post Office. I look forward, instead of an increase of expenditure from this item, to a diminution. A small item of increase has been involved in the repairs to the steamer, which is, I may say, in better condition than it has ever been since we owned it. After a great many years' work, our surveyor and Lloyd's surveyor reported that the cylinders of the vessel were not fit to be used any longer. Everything wears out on steamers as well as on shore, and the result was that we had to put new cylinders into it. That cost us £1,655, but it came out of the fund which has been provided for repairs to the steamer from time to time, and therefore it does not affect this half year's dividend. But there were certain general repairs which we thought it desirable to effect in order to put the ship in a perfect condition, and we accordingly did them. On the whole, I must say, as far as I am concerned, that I do not think that this condition of affairs is unsatisfactory. But there is one thing that I have to mention which is not satisfactory, and that is this—in the course of last year the French Government made an application to us of an entirely new character. Our relations with the French Government during the many years of the concession have been regulated of course by that concession, and up to last year no such demand as the one which I am now about to mention was ever made upon us. But last year they applied to us not only for the payment of clerks at Calais, Boulogne, Dieppe and Havre, our four coast stations where our cables are landed, and where they are connected with the French Government lines, but they also asked us to be good enough to pay what we never paid before, namely the clerks at Paris, Bordeaux, Lille, and Rennes, who were employed on the wires directly connected with London. For instance, there is what is called a special Bourse wire from the Stock Exchange here to the Bourse in Paris, and they proposed that we should pay the clerks engaged on it. Well, according to the wording of the concession, which has been acted upon as I say during all these years, we have no doubt that this demand was not a legitimate one. But we took the very best advice of lawyers accustomed to international contracts both in England and in France, and our view has been strongly confirmed. At the same time, in a memorandum which we placed before the French Government, we told them what our position was in this matter; but M. Cochery did not express himself satisfied, and nearly six months ago cited us before the Tribunal of the Seine, which in the first instance would have to investigate this matter. In answer to the citation, the most able lawyer in France had drawn up a very admirable statement on behalf of the Company, and it was presented three months ago, but from that day to this no further step has been taken by the French Government. When we look at all the facts of the question, I think we shall be able to prove to the tribunal that this claim is perfectly unfounded. But I do not desire to say anything more about this, and I trust when the case comes before the tribunal that it will be decided in our favour. The additional amount which will be drawn from the revenue of this Company, if the French Government should turn out to be successful, will be the sum of £3,618 13s. 9d. That of course is a very serious amount to be charged with; and, consequently, I think it is the business of the Board to resist it if possible. I do not think it is desirable that I should say anything more on the subject. It is a delicate matter, and has to be treated by the Board with the greatest possible care. We are very anxious to act in a friendly way with the French, Belgian, and Dutch Governments. So much with regard to the general business of the Company. The new cable, as I announced, which the Post Office laid down to Holland is an admirable one, and was completed with the assistance of our engineer; and the Post Office are now repairing the second Dutch cable by putting in a large amount of new wire. After that, I believe that both these cables will be in excellent order; and I may say that we have done our best to maintain our property in as good a condition as could be. I think, on the whole, though the dividend is slightly reduced, owing to the decrease of income and the increase of expenditure, even now under the unfavourable circumstances of trade and the complications in the East a dividend at the rate of 14 per cent. per annum is not to be despised, and therefore I, for my part, have much satisfaction in proposing to you that the report now submitted be received and adopted.

The Right Hon. ROBERT BOURKE, M.P., seconded the motion, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by the Hon. ASHLEY PONSONBY, a dividend at the rate of 14 per cent. per annum, free of income-tax, was subsequently declared.

Mr. ROSTRON proposed, and Mr. SERMON seconded, a vote of thanks to the Chairman.

The CHAIRMAN: Gentlemen, I am much obliged for the observations that have been made by Mr. Rostron and the seconder of the resolution. The Board are anxious to do their best in the interests of this Company, and I for my part am desirous to give the shareholders all reasonable information so long as I have not to say anything that would prejudice us in our business. There are in this business, as well as in others, some little secrets that we do not like to divulge to all the world.

The proceedings then terminated.

The Maxim-Weston Electric Company.

An ordinary general meeting of the shareholders of this Company was held at the City Terminus Hotel, Cannon-street, on Wednesday last, under the presidency of Mr. Hugh Watt, the managing director.

The notice convening the meeting having been read, the Directors' report and the statement of accounts were taken as read.

The CHAIRMAN said: Gentlemen, it is now about nine months since I had the pleasure of addressing you, and, from the report and balance-sheet placed in your hands, you will have seen the result of the Board's work during that period. I have no intention of reminding you that in no decade during this century has the commercial temperature approached so near to the zero of starvation, or of the fact that few, if any, of the stable industries of our country have shown any return upon capital, as these facts are familiar to every shareholder in the Company. But for the state of trade the returns we would have been enabled to show would have been more in accordance with my hopes and expectations of a year ago, and more commensurate with the efforts of your Directors. Another event which has materially interfered with this Company has been the state of chaos in which the affairs of the Lancashire Company was found. As a proof that the policy I proposed to the Lancashire Company, viz., to confine their business to sales, was a correct one, since June of last year ten installations have been sold in Lancashire, and there are now in Manchester and Liverpool some of the largest private installations of our systems which are to be found in this country. In the matter of prices, as the American Company decided to abandon Maxim dynamos and lamps, I was enabled to lay in a large stock at very low prices, all of which I have since sold, so that the profits we have made are, to a large extent, due to large reductions in the purchase prices, as well as to the fact that recent improvements in appliances have enabled us to run a much larger number of lamps off the same machines, enabling us to maintain the sale prices in most cases at those of last year, and yet show a large relative reduction to purchasers. I think you will, from what I have said, fully appreciate the vantage ground the Company now occupy compared with a year or two ago. There is now only one branch in which the Company cannot be said to be in the van of progress; and as we have inquiries for the execution of large orders in this department, we are now actively engaged in formulating the data to enable us to alter the proportions of our dynamos, so as to compete and, I hope, secure large orders during the present year. We have recently had to increase our staff materially, so as to finish with promptitude the orders in hand. At present the Company have sufficient work to keep us engaged for three months. The expenses of the Company are now on the lowest possible scale. In every department economy has been the order of the day, and I have personally superintended nearly every detail connected with the practical at the works, and the commercial and financial at the offices. I will now refer to the report and balance-sheet; but before doing so, allow me to thank numerous shareholders for their kind letters, and to assure those who have sent queries that I am at all times pleased to find my co-proprietors showing an interest in the business of the Company. And first to deal with the most important part of it—namely, the profit and loss account. You will observe that considerable economy has been effected in working expenses, which have, however, slightly exceeded my estimate, occasioned by the necessity for an increase to our staff. Since the 1st January, 1885, we had to nearly double our staff, so as to complete within the desired time contracts now in hand, some of which are larger than any we have yet undertaken. As you will see by the balance-sheet which has been placed in your hands, the net profits for the nine months from 1st April, 1884, to 1st January, 1885, are £4,975 13s. 2½d., which is nearly equal to a dividend at the rate of 6¼ per cent. per annum. From this sum, however, has to be deducted the deficit to the debit of profit and loss account last year, after crediting the reduction of capital then agreed to, and since

Digitized by Google

sanctioned by the Court, which with further sums we have had to pay in connection with contracts entered into by the old Board amounts to the large sum of £2,544 14s. 7d. The reduction thus caused makes a very great difference in the net balance for the nine months. And now, with regard to the balance-sheet, the first item, patents, remains as formerly, although the Company now possess a new self-regulating dynamo of great efficiency, equal, I believe, to anything in the market, and much cheaper than our new Weston, and I reaffirm what I stated last year, viz., that the new patents acquired by this Company during the last twenty or twenty-one months are themselves intrinsically worth the whole amount charged against patents account, independent of all the other patents in the possession of the Company, besides those of which we may become possessed, we being entitled to all new inventions of the American Company up till 1887. Looking at the question from another point of view, I think you will agree with me that the Company is now in a position to justify us in assuming that in the near future your Directors ought to be able to declare dividends on a scale which investors in such an enterprise are entitled to expect. The next item, as you will see, remains very much the same as last year, although all the stock excepting fixed plant now in hand is new. The third item, viz., securities, is the same, excepting the shares in the Scotch Company, which I succeeded in selling at a price slightly in excess of my last year's valuation. The fourth item, debtors to the Company, is a large one—more so than last year, if you include cash due from the Lancashire Company, which was dealt with last year among the ordinary trade debts due to the Company—owing to the fact that a large portion of this consists of shipping orders and consignments not very long ago despatched, we having found it advantageous to replace stocks sold at once, thus saving a delay of several months in time. This branch of the business the Directors have been pushing energetically, as we find it easier to get our list prices abroad than at home. You will, I am sure, agree with the Directors that the reserve of £800 was a wise step to take, even although it militated against the amount of dividend paid, and although the debtors to the Company are of an exceptionally good class, the Board having exercised the greatest care so as to prevent bad debts, preferring rather to let orders go past us. Fifth, that of creditors, you will see the claims are small, and at the present moment these, excepting two small American drafts not yet due, have been paid. The balance-sheet is prepared, therefore, exactly on the lines of last year. The present Board have throughout conducted its business on the cash principle as regards payments, which you can understand has been a somewhat difficult matter in view of the business we have done—one quarter's business alone amounting to nearly double the capital of the Company—and the fact that when the present Board took office we had second-hand plant worth not more than £3,000 of market value ; and the surplus left from the shares, chiefly subscribed for by my friends and self, after paying the old Board's debts, amounted to only about £2,500. Thus, gentlemen, the result of our first year's trading has led to a net profit of nearly 50 per cent. of our capital, and the last nine months of nearly 100 per cent. net profit. To rescue a company from the verge of the irrevocable precipice of liquidation, sunk in debts, with expenses of about £17,000 a year, against a revenue of about £3,000, with commitments of a ruinous character, the liquidation of which has even during the last nine months cost us an expenditure of about £500, has not been child's play. I will not detain you longer, and I have only to add with regard to dividend that this is necessarily small, as the Board had to make up the deficit in profit and loss account last year before making any return to the shareholders. I think I have now touched on all points requiring reference in the report, balance-sheet, and profit and loss accounts, and do not know that there is any other point of interest to which I can refer. Gentlemen, I am glad to see from the large and influential attendance here to-day, at an hour which is probably not convenient to some of you, that so many shareholders feel an interest in the Company. Without detaining you longer, I beg to move the adoption of the report and accounts and payment of the dividend of 5 per cent. for four months, payable as soon as dividend warrants can be printed and sent out. I should explain that I am entirely responsible for the recommendation that has been made with regard to the dividend. My colleagues certainly did not emphatically differ from me on the subject, but, as I have stated in the short address which I have ventured to submit to you, you are as well aware as I am that the cash reserve of the Company is a very small one, and I may say, therefore, that my colleagues have some diffidence as to my proposal, and have since expressed to me their personal feelings to the effect that a wiser course to pursue under the circumstances would have been to carry forward the entire balance. Of course you know, gentlemen, that is a matter for your arbitrament. I must say, however, considering the fact that for two or three years we have paid no dividend, and bearing in mind that many people are mixed up in this Company who can ill afford to lose the money they have invested in it—invested, too, at the fictitious prices paid some years ago—I felt it my duty to submit the proposal I have done, seeing that we can honestly show a surplus. At the same time, as my colleagues have considerable aversion to that course, for which, as I say, I take the responsibility, if any gentleman here has any proposal to make with regard to it, I am sure we shall all be pleased to listen to it before going any further in the matter.

Mr. Louis Swaby seconded the motion.

Mr. Gray said that, with regard to the payment of a dividend, he must say that, like every shareholder in every other company, he would like to "taste blood." He was most agreeably surprised on reading the report to find in it the suggestion made to declare a dividend in an electric lighting company—a condition of things which hitherto they had not had the good fortune to experience. But he would ask the Chairman to reconsider whether it would not be better, in the interests of the shareholders, not to pay the dividend, and reserve the money for the working purposes of the Company. The whole social and commercial atmosphere was full of electricity at the present moment, and he saw a great future for electrical industry, and having regard to that fact, he made the suggestion to withdraw the recommendation. He concluded by moving an amendment to the effect that the motion as proposed should be accepted, subject to the proviso that no dividend be declared at present.

Mr. Makewood seconded the amendment, believing that it would be the wiser course for the Company to adopt, seeing that as yet they were not financially in a very strong position. He had no doubt that by so doing they would more than recoup the apparent sacrifice they were making by giving the Company a better status, and enabling it to carry on its work more cheaply and effectively.

Mr. Gray was here understood to ask what the relations of the Maxim Weston and the other companies were with respect to the competition for business.

The Chairman said that since he became connected with the Maxim-Weston Company he had made it his duty to attend to his own business. He never paid the slightest attention to that of any other companies When they had crossed his path in honest competition he had done his best to oust them. Where he had failed he had submitted, as any man ought to do. He had often met with very dishonest competition. He thought that when a man gave £100 value for £20 it was very dishonest competition, and the Board had had to contend with something like that —with companies, for example, if not in liquidation, in the chrysalis stage of it, to whom the realisation of their plant meant a matter perhaps of directors' fees—he did not know that for certain—but at any rate some assistance to carry on the undertaking for a little longer. During the past year they had had to fight a hard battle to keep the concern going, and they had now pretty well established a good business. With regard to the Lancashire claim of £10,000, Mr. Dever, the auditor, thought, and he (the Chairman) agreed with him, that it ought to appear as a separate item in the accounts, and should not be included, as Mr. Gray had hinted under the first item on the credit side of the balance-sheet, namely patents, which stood at £70,000. With regard to the closing of the books for nine months, he might explain another point. In revising the Articles of Association in connection with another matter, they came on a clause making the year end on a certain day, and discovered that they were labouring under a misapprehension as to the interpretation of these Articles. As least such was the opinion of their solicitors, which, of course, he did not wish to set against the opinions of those who had gone before ; but at the same time they believed that the books ought to be closed on the 31st of December of each year, and when they came on the clause referred to he rapidly took stock at the works, in conjunction with the works manager, and hastened the preparation of the balance-sheet as soon as possible. The amount of cash at the bankers, and bills—a thousand guineas—might appear small, but it must be remembered that they sent out their accounts quarterly, and naturally they did not send out their Christmas accounts until the second week in January. But as far as they could ascertain all their debts were good. He might mention the circumstance, as a proof of the value of their assets, that within two weeks from sending out these quarterly accounts they received a sum equal to a third of the entire amount outstanding. Considering that a large sum of that was due abroad, and could not be received otherwise than by remittance, they would understand that that was a large percentage to be received so soon. He was extremely sorry if he had made a recommendation to declare a dividend of which they did not approve ; at the same time he trusted they would give him credit for failing on virtue's side. He was anxious to make some return to the shareholders. He thought it right to say in regard to the amendment that had been proposed, that he had received proxies against the payment of the proposed dividend to the extent of 30,000 shares ; and he took it as an exhibition of confidence in the present Board that the honourable proprietor who proposed the amendment, and who was about the largest shareholder in the Company, had been pleased to say he would prefer not accepting the dividend recommended One of the most eminent authorities on electric lighting in this country said to him (the Chairman), in pressing him to give an exhibition of their appliances—a thing hitherto contrary to the policy of the Board—"I consider that no exhibition in this country would be complete without an exhibit of the Maxim-Weston apparatus." There was no doubt that Weston had made for himself a good name in America. They might not be so conversant with the matter as he (the speaker) was, but he agreed to give that exhibit, and possibly in a few months' time they would see one of the most perfect displays of their system which had yet been shown in this country.

Mr. Parnell thought, after what the Chairman had said, it would be foolish to decline accepting the dividend, seeing that the business was increasing and prospering.

Mr. John Brown (Director), who was asked by a shareholder to give the reason why he was averse to the paying of a dividend, said that he thought if the money to be divided were left in the coffers of the Company it would be returned to the shareholders not only doubled, but trebled before the year was out. The Company could do more with the money as working capital than the shareholders could with it as a small dividend.

The Chairman, in reply to another question, said the Company could unquestionably afford to pay the dividend, otherwise he would not have recommended it. He did not regret making the proposal, having acted according to the best of his judgment, and if he had erred he was sorry for it, now that it appeared the feeling of the shareholders was against the recommendation. He ought also to mention that Mr. Dever, an auditor of great experience, was in sympathy with the view of Mr. Gray. He then put the amendment in the usual manner and declared it carried.

A letter from Mr. Dever, bearing on the subject of the balance sheet was here read.

Messrs. Brown and Watt, the retiring Directors, were afterwards re-elected, and Mr. Henry Dever re-appointed auditor.

Digitized by Google

Mr. GRAY, in a few sentences eulogising the services of the Board, proposed that Mr. Brown and Mr. Swaby should receive £100 each as an honorarium for their labours, and that it should be made an annual charge to the Company.

The CHAIRMAN having offered a few remarks bearing testimony to the zeal of his two colleagues, and the amount of hard work they had gone through in the interests of the Company,

A SHAREHOLDER seconded the motion, and it was carried unanimously, and a vote of thanks having been passed to Mr. Watt the proceedings terminated.

Lancashire Maxim-Weston Electric Company.

An extraordinary general meeting of the shareholders of this Company was held at the City Terminus Hotel, Cannon-street, on Thursday last, for the purpose of considering, and if approved passing the following resolutions:—1. "That the sanction of the Company be hereby given to the terms of compromise by the liquidators of the Company of the two actions now pending in the High Court of Justice, between the Company and James Thornton Dadson, and between the said J. T. Dadson and the said Company and Hugh Watt, contained in an agreement dated the 21st day of January, 1885, and made between the liquidators of the said Company and the said James T. Dadson and the said Hugh Watt, whereby it is in effect provided that the actions shall on the payment by the said James Thornton Dadson to the liquidators of the sum of £737 10s. be compromised." 2. "That the sanction of the Company be hereby given to the terms of compromise by the liquidators of the Company, of the action now pending in the High Court of Justice between the Company and Gustavus Palmer Harding, contained in an agreement dated the 2nd day of December, 1884, and made between the liquidators of the one part and the said G. P. Harding of the other part, whereby it is in effect provided that the said action shall on the payment by the said G. P. Harding to the liquidators of the sum of £850 be compromised."

On the motion of Mr. GRAY, seconded by Mr. THOS. CORDELL, Mr. Hugh Watt was called upon to preside.

The CHAIRMAN having read the notice calling the meeting, said that with regard to the business before them, which was embodied in the two foregoing resolutions, he trusted every shareholder would agree with him as to the desirability of compromising these actions. At the same time he must say this, more especially as there was at least one gentleman present who was as familiar as he (the Chairman) was with the whole history of this Company, and he thought it due to the Company, in the formation of which he took an active part along with that gentleman, to point out that the Lancashire Maxim-Weston Company started under most favourable auspices. There had been a neucleus of the business formed there, and in the event of the capital which had been applied for and allotted having been paid, the Lancashire Maxim-Weston Company would have occupied a position to-day second to none in this country. He did not think that could be questioned. Nor could it be questioned, he believed, that the action taken by certain gentlemen in connection with the Company who had duly applied for and had had allotted to them a large number of shares had largely helped to bring about its collapse. The non-payment by those gentlemen of their calls placed the Company in a most unfortunate position. No one could regret that more than he could, because he was responsible for a considerable amount of the capital subscribed. He thought it only justice to the promoters of that Company, who were the parent Company, no promotion money having been paid, no cash payment having been paid to them, and remembering that even the plant which was there and fairly valued was only paid for to this day to the extent of about two-thirds its value, he thought it only justice to them and to the honourable Board of that Company to say that he sincerely regretted the condition in which the undertaking stood to-day. It was through no fault of theirs, but through the non-fulfilment of contracts entered into by certain parties, with regard to which all he could say was this—that so far as the Company was concerned every condition was complied with which was asked for or agreed to, and their nonfulfilment was simply because to his mind the market went against them, and the shares were not of the par value which had to be paid for them. There was no future for this Company, so that he trusted the compromise which had been effected—he might say after very great trouble, because one of the parties was not resident in this country, and had, as far as he (the speaker) knew, no effects in this country which could be seized, and by means of which the payment could be secured—would be approved by the meeting. He thought that the compromise arrived at in respect of the second party was the best that under the circumstances was possible. In justice to the liquidators he must say, before sitting down, that having done what in them lay to further the objects of this liquidation, having gone to a vast amount of trouble, and been untiring in their exertions to bring about the best settlement of the affairs of this unfortunate enterprise, they were entitled to the best thanks of those interested in the concern, and out of deference to those gentlemen he hoped, in moving the resolution, there would be shown that unanimity in the meeting which he thought was only a fit recognition of the labours the liquidators had undergone. He concluded by formally moving the first resolution, which was seconded by Mr. SWABY, and carried unanimously.

The CHAIRMAN then proposed the second resolution, which was seconded by Mr. WHITWORTH, and agreed to.

Mr. BROWN afterwards gave a brief history of the circumstances which led up to the compromises referred to in the resolutions.

This concluding the business, the CHAIRMAN reminded the shareholders that there would have to be a confirmatory meeting, and suggested that the question of granting some special increment to the fees of the liquidators should be considered at it.

A vote of thanks to the Chairman brought the proceedings to a close.

India Rubber, Gutta Percha, and Telegraph Works Company.

Directors' report for the year ended 31st December, 1884, to be presented at the twenty-first ordinary general meeting of the shareholders, to be held at the Cannon-street Hotel on the 24th inst., at 12 o'clock noon.

The net profit for the past year amounted to £68,968 10s. Adding £37,902 3s. 3d. brought forward, and deducting £15,600 interim dividend paid in July, there remains a disposable balance of £91,270 13s. 3d. The Directors have added £20,000 to the reserve fund, and recommend the distribution of a dividend of one pound per share, amounting to £31,200, and making, with the interim dividend, a total payment for the year of 15 per cent., free of income tax, carrying forward £40,070 13s. 3d. Both in general sales and in cable work the amount of business has been considerably in excess of that for 1883, apart from the cables manufactured for the Spanish National Submarine Telegraph Company, the laying of which is completed, the subventions from the Spanish and French Governments being regularly paid. The Company's Bill in Parliament was passed last year. The Directors, in view of the steadily increasing business of the Company, have long felt that great advantages would be secured by having available a considerably larger amount of working capital. In this connection the reserve fund has been of the greatest value to the operations of the Company; but now a still wider development of business is opened up, not only by the continued growth of old branches, but also by the new work authorised by the Company's Act of Parliament. They have therefore resolved to increase the capital, in accordance with the powers conferred upon them by the special resolutions of the shareholders in June and July, 1864, by the issue of 10,400 shares of £10 each, thus increasing the total issued capital from £312,000 to £416,000. The new shares will be allotted to the shareholders at the price of £15 (being at a premium of £5 per share), in the proportion of one-third of a new share for every old share, or one new share for every three old shares.

NOTES.

TELEGRAMS FOR AMERICA.—The cable of the Direct United States Cable Company has been repaired.

REMOVAL.—The offices of the New Telephone Company have been removed from 39, Lombard-street, to 4, Great Winchester-street.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 20th February amounted to £3,491.

LALANDE AND CHAPERON'S BATTERY.—Forty couples on this system have been installed in the Paris central telegraph office, in place of 200 Callaud couples.

APPOINTMENT.—Mr. Henniker Heaton has been appointed by the Tasmanian Government to represent them at the Telegraphic Convention at Berlin in May next.

LIGHTING ON THE GOTHARD RAILWAY.—The first locomotive fitted with electric light apparatus lately left Lucerne for the St. Gothard Tunnel, and it is said that the company intends to apply the system to all its trains.

THE TELEPHONE IN THE NORTH OF ENGLAND.—It is said that the Northern District Telephone Company are about to connect the Hartlepools with Sunderland and Newcastle, and with Stockton, Middlesbrough, and Darlington.

FRANCO CHINESE WAR.—The *Daily Telegraph's* Paris correspondent wires that General Brière de l'Isle is at present engaged in repairing the Bac Le road, and in establishing telegraphic communication between various places.

ELECTRICAL LIGHTING AT THE SOUTH KENSINGTON MUSEUM.—It has been decided to use a set of the Electrical Power Storage Company's accumulators for the maintenance of 100 lamps in the Science and Art Department.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 20th February were £2,760, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

SOCIETE BELGE D'ELECTRICIENS.—One of the youngest of scientific bodies, the Société Belge d'Electriciens, has already made great and commendable progress. During a year of existence no less than 240 candidates for membership have been elected.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th Feb. were £2,319, as compared with £3,031 in the corresponding period of 1884. The November receipts, estimated at £4,456, realised £4,514.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY. Notice is given that the transfer books of the company will be closed from the 23rd inst. to the 3rd prox., both days inclusive, preparatory to the payment of dividend to all shareholders on the register on the 23rd inst.

VERY LONG-DISTANCE TELEPHONY.—The *Bulletin Internationale des Téléphones* says that the Belgian Government has arranged with the French and Spanish authorities for experiments in telephony between Brussels and Madrid. It is proposed to use the Dembinski microphone.

TELEGRAMS FOR THE WEST INDIES AND BRITISH GUIANA.—The West India cables interrupted are now repaired, with the exception of those between St. Vincent and Grenada, and between Trinidad and Demerara. Telegraphic communication is therefore restored with all places in the West Indies, except Grenada and Trinidad.

ELECTRICITY FROM SUGAR.—Signor Salvatore Mazza writes from Palermo to *Il Giorno* that he has obtained electric sparks, about 3 centimetres or an inch long and of a colour between blue and fiery yellow, while braying sugar in a copper mortar with a wooden pestle, and that he has seen the phenomenon repeated with copper and iron pestles.

ELECTRICITY AT ASSAB.—*Il Giorno* says that the Societa Industriale Franco-Italiana has sent one of its catalogues to Messedaglia Bey, offering him some electrical apparatus, which may be useful in the Red Sea expeditions, and also prove a source of gratification to the chiefs of friendly tribes. Assab is an Italian settlement on the East Coast of Africa.

ELECTRIC LIGHT AT THE MANSION HOUSE.—On Thursday evening, at the banquet to the masters of the City companies, the new electric light, supplied by the Hammond Electric Light and Power Supply Company, was tested at the Mansion House. The incandescent lamps have been placed in the saloon and the Egyptian Hall, there being 127 in the former, and 142 in the latter.

SKATING BY ELECTRIC LIGHT.—Referring to a recent note as to skating on the lake in the Bois de la Cambre, Brussels, we learn that the lighting was done by the Compagnie Belge et Hollandaise. The fourteen Brush arc lamps were supplied with current by Faure accumulators, charged by the dynamos put down in the Rue de La Loi, in connection with the electric tramway tugs that were to have superseded horses six months ago.

PROGRESS OF ELECTRICITY.—*Il Giorno* is responsible for the following, copied by *l'Electricien*:—A gentleman, travelling with a Yankee, observes: "Grand country, yours; only two centuries ago peopled by savages; what progress and what marvellous results of civilisation!" "Certainly," replied the Yankee, "we have reached such a high degree of civilisation that even in our virgin forests all the rattlesnakes have electric rattles."

THE TELEPHONE IN NEW ZEALAND.—The telephone is getting very popular in New Zealand. There are nearly 1,100 subscribers in the colony. The list continually goes on expanding, and a new annunciator is being prepared for Auckland and another for Wellington, while one has just been supplied to Dunedin. There are also about 100 country stations where the telephone is used, instead of the Morse instrument, for telegraphic purposes.

SOUTH AFRICAN CABLES.—The Eastern Telegraph Company announce the repair of the Eastern and South African Company's Zanzibar-Mozambique cable, thus re-establishing telegraphic communication with the East Coast of Africa, Natal, and the Cape of Good Hope. The Directors have resolved to duplicate this section, and the ss. "Great Northern" is now engaged in sounding, with a view to the selection of a better *route* for the new cable.

ELECTROLYSIS OF PHENOL SOLUTIONS BY CARBON AND PLATINUM.—A. Bertoli and C. Papasogli, continuing their researches into the disaggregation of carbon electrodes in different organic compounds, describe a series of new compounds which they have met with in taking, as electrolytic liquid, a solution of carbolic acid in the hydrate of potash or soda; among others they found an acid $C_7 H_6 O_4$ which belongs to the series of dioxibenzoic acids.

OPTICAL TELEGRAPH.—A system of optical telegraph is being tried, in which an incandescent lamp is placed in the

Digitized by Google

middle of a hollow globe made of white cloth, varnished; the lamp being in electrical communication with a battery. When the current passes the globe appears luminous, and is, of course, instantaneously darkened on the current being interrupted. This system has the advantage of giving but little trouble in the transport of apparatus.

THE ELECTRIC LIGHT AT BRADFORD.—The plant recently put down at the office of the *Bradford Observer* consists of one four-unit Crompton dynamo, of the latest improved type of wrought iron, and 75 twenty candle-power Swan incandescent lamps, the power being supplied by an eight horse-power Otto gas engine. The editorial department, the composing room, and the various offices, as well as those on the ground floor, are well and efficiently lighted. The report of Messrs. Byles upon the working of the apparatus is very favourable.

THE AMALGAMATION OF ZINC.—The following directions are given for amalgamating zinc; and, when used for batteries, this must be done carefully:—First, wash the plates in water acidulated with sulphuric acid and then in pure water, when they must be immersed in a solution composed of three-quarter part of mercury, one of nitric acid, and two of muriatic acid. When the mercury is well dispersed two more parts of muriatic acid are to be added. The immersion should not continue for more than about thirty seconds, after which the plates are to be again washed in pure water.

ELECTRIC LIGHT AT TURIN.—Following the example of Aosta, the Turin Municipality has decided to light the Po, Roma, and Garibaldi streets with Edison, Siemens, or Cruto lamps. As the problem of utilising the force of waterfalls and transmitting power to a distance is not yet practically solved, the municipal authorities have made an arrangement with Gaulard and Gibbs, who intend to use the motors which now serve for the Superga railway. The two gas companies will allow the above-mentioned firm to put up in the streets the necessary appliances for arc lighting.

SOUTH OF ENGLAND TELEPHONE COMPANY.—The South of England Telephone Company has received from the Postmaster-General the license, for 27 years, for the establishment and working of telephone exchanges in the district acquired by the above-named Company from the United Telephone Company, viz., the Counties of Northampton, Norfolk, Bedford, Cambridge, Huntingdon, Buckingham, Oxford, Berks, Suffolk, Sussex, and those portions of the counties of Kent, Essex, Surrey, and Hertford which are not included in the Metropolitan area of the United Telephone Company.

LIGHTING OF STRASBURG STATION.—The Elsass-Lottringen Railway Administration decided to adopt electricity for lighting the Strasburg station, although believing it to be more costly than gas, because it would better light up every part, including the sidings. Facts, however, prove that, not only is the electric light no dearer than a corresponding illumination by gas, but that it is even cheaper. The cost of the main installation was 25,154f. (£1,006), and of the supplementary one 8,106f. (£320), while the corresponding prices for gas would be 51,815f. (£2,032), and 9,802f. (£392).

GAS V. ELECTRICITY.—In Lockport, N.Y., a company was formed to introduce electric lighting, and it obtained permission to erect poles and wires in the streets. After this a gas company bought a controlling interest in the electric company, and it was thought this would end the electric light business, but soon after a new company appeared and obtained the privilege to light several streets by electricity in place of gas. Ultimately the gas company commenced to pull down their gas posts and to put up poles for the electric light in Main-street, which right had been given to the new company. A war of words between officers of the two companies ensued, and trouble is expected.

BRUSSELS ELECTRICAL EXHIBITION.—*L'Electricien* says that 1887 is the year fixed for the Brussels Gas-lighting and Electrical Exhibition. A provisional council is appointed, with M. Besme, architect, as president; and several meetings have already been held at the Bourse. Plans, prepared by M. Wybau, the city engineer, utilising for the purposes of the exhibition the Palais du Midi with the adjoining streets and boulevards, have been submitted to the committee, which includes several common councillors, and has already secured the co-operation of the Société Belge d'Electriciens, represented by its president, Professor Rousseau, and the secretaries, M. Charles Mourlon and M. Adolphe Lebégue.

BUCHIN AND TRICOCHE BATTERY.—At the meeting, on 31st January, of the Anciens Elèves des Arts et Métiers, in the Rue Vivienne, Paris, the hall was lighted by three incandescent lamps, two Swan and the other Gérard. Each of the Swan lamps received the current of ten No. 2 bichromate elements; and the Gérard was maintained by two batteries of 25 cells, No. 2 type, connected in multiple arc and filled with bichromate of potash, yielding a luminous intensity of 50 candles. A No. 1 bisulphate of soda battery of four elements supplied the current to a telephone line set up in the hall; and though the circuit remained closed for four hours, communication is said to have been as distinct at the end as at the commencement of the meeting.

ELECTRIC LIGHT AT THE PARIS ELYSEE.—Although the accounts of Central African expeditions have, it is rumoured, been evolved in the vicinity of Fleet-street, and the exciting details of many a British victory, and so forth, had their origin in the same quarter, it is somewhat unusual to find the correspondent of a leading newspaper omitting items of general interest to the public. An official ball was given last week at the Elysée, in Paris, and the salons were successfully lighted by electricity. The innovation seems to have met with universal approval. The temperature, which has hitherto been a source of complaint, was not only bearable but pleasant; and the large conservatory, with its wealth of tropical plants and giant ferns, was bathed in cool light. How was it that M. de Blowitz said nothing of this in his letter to *The Times* describing the Elysée gaities?

GERARD'S INCANDESCENT LAMP.—The new incandescent lamp of M. A. Gérard has two very fine carbon filaments, made by being drawn through a plate, like the carbons of arc lamps, thus ensuring great homogeneity. By suitably proportioning the length of the carbons to their diameter, the consumption of the lamps in volts and amperes may be varied at pleasure, thus obtaining a wide range of luminous power from 2 or 3 candles to 500, or more. The carbons are joined together at their summit by a carbon paste, and are received below by two carbon cylinders of larger diameter, in connection with platinum wires which are soldered to two armatures embracing the lower portion. The lamp is put in place by inserting it into a spring socket, which is fixed to the bottom of the lantern.

PORTABLE ELECTRIC LIGHT APPARATUS.—M. Anatole Gérard has devised portable electric light apparatus for illuminating a building which might contain an explosive atmosphere. The dynamo, to be worked by two men at a crank, and everything else necessary for incandescent lighting are carried on a truck, which remains outside the building, while the lamp is taken in by a fireman, for instance, the light cable

Digitized by Google

which contains the two conductors unrolling as he proceeds. The lamps, on the latest Gérard system (as described in another note), are enclosed in lanterns of different forms, some arranged for being carried in the hand, and others fixed to the end of a staff for examining a chimney, a soil-pipe, or a well, the lower end of the staff being pointed, so that it may be stuck in the ground.

HOUSE TO-HOUSE SUPPLY OF CURRENT.—Sig. Meardi has proposed a system for the house-to-house distribution of current, which depends on the following principles:—1. Distribution in series of the conductors to the appliances utilising the current, whether lamps, motors, accumulators, or electro-plating batteries. 2. Subdivision of the intensity of the current among the line conductors in different proportions, the conductors being therefore composed of various materials, but of small section, insulated and completely independent of each other. 3. Differential system of counter-tensions and variable auxiliary resistances, with automatic regulators that may be worked by hand on receiving an oral signal from the tension indicator attached. 4. Utilisation of the series at will, with slow and progressive graduation of the resistances, when the series is put in and out of circuit.

FRIENDLY AID OF THE ELECTRIC LIGHT.—The Brentford Gas Company are building a new gasholder, and, wishing to proceed with all possible speed, applied to Messrs. R. E. Crompton and Co. for a machine arc light. The electric light accordingly came to the rescue, and a brilliant arc of about 4,000 candle-power now illuminates the interior of the gasholder, and enables the work to be carried on with great speed at all hours. The engineer states that "the light answers admirably," and they are enabled to get through the work in half the time they would have done without it. This rather novel application of electricity to aid in the manufacture of gas should be a lesson to our opponents that the electric light in some instances can be a valuable auxiliary to gas itself. It also appears that the Brentford Gas Company are more enterprising than many of their neighbours.

ATTRACTION BETWEEN SUBSTANCES IN SOLUTION AND BODIES IMMERSED IN THE SOLUTION.—In a recent note, we referred to the experiments of M. Toulet, which show that, when a salt is dissolved in a liquid, and the solid body is immersed in the solution, there is an attraction between the salt and the solid body, independently of chemical action. M. Thoulet attributes to this attraction, which is proportional to the surface of the immersed body, the following phenomena:—(1) Impurity of most chemical precipitates, especially those that are gelatinous; (2) Diminution of the concentration in saline solutions discoloured by animal black, or alcaloids, and also the action of glutinous substances, such as blood and albumen, used for clarifying liquids; (3) purification of surface water and sewage; (4) the fact that clay, remaining indefinitely suspended in distilled water, is quickly precipitated in water containing salts in solution.

LA REINE DES BELGES, ELECTRICIENNE.—The love of music by the Queen of the Belgians is second only to Her Majesty's fondness for horses. The former passion was lately gratified (as recorded in *The Electrician*) by the transmission of Gounod's "Faust" from the Brussels "Monnaie," or Opera House, to the royal châlet at Ostend, where the Queen was able to enjoy the opera without quitting her boudoir. This feat evidently inspired the royal auditor with a profound respect for electrical science; and Her Majesty set about studying its principles, being aided in the task by M. van Rysselberghe, the inventor of simultaneous telegraphy and telephony, and Mr. Charles Mourlon, who successfully applied it to the Belgian telegraph lines. Such progress has been made by the august pupil that already the title of "*électricienne*" has been conferred by common consent, while the professors have been rewarded by Her Majesty with valuable presents for their share in the result.

DETERMINATION OF THE OHM.—In a recent note before the French Academy of Science, M. Mascart remarks that all methods give a greater length than 106 centimetres of mercury, except that of neutralisation (*amortissement*), while this method has, on the contrary, always given a lower number; and he inquires if a more complete interpretation of the theory might not furnish an explanation of this difference. It results from his researches that the correction to be made in the approximate calculation of the resistance, taking into account the coefficient of self-induction, should be somewhat less than that usually made, and that the strong induced currents should give the bar, in a transverse direction, a temporary magnetisation, which must be taken into consideration. These two corrections contribute to increase the value of the intensity of resistance hitherto found by the method of neutralisation, which fact explains why the figures which it gives have always been found under the mark.

CURATIVE ELECTRICITY AND CONDENSERS.—In a recent communication to the Société des Electriciens, Paris, Dr. Boudet established the fact that the method of excitation by the discharge of the condenser, employed in physiological laboratories, and introduced by him a few years ago into therapeutical practice, is the only one which has hitherto given exact results always comparable with one another. It is similar to the excitation by the galvanic shock, but possesses over the latter the advantage of not irritating the skin by its chemical effects. The condenser should be preferred to the induction coil whenever it is not required merely to awaken the sensibility of the skin, and when it is desired to take into account the excitation employed, because, with coils, induced currents are used irrationally, and without seeking to appreciate their mechanical value. Dr. Boudet concludes by observing that, as electricity is *par excellence* the science of progress, the physician who employs electric currents should, more than any other, avoid lagging behind.

MUSIC AND THE TELEPHONE.—In connection with a concert given at Inverness last week, an experiment was made by the National Telephone Company. A wire connected the hall with the Telephone Exchange office, and several subscribers, in different parts of the town, were placed in communication. In the office itself the concert could be heard with singular distinctness, and even when the sound was distributed through the various connecting wires, the listeners at a distance could distinguish and enjoy the entertainment in the hall. The instrumental music and the choruses were heard most distinctly at a distance of over a mile, while some of the vocal solos were quite distinguishable. Two ordinary Blake transmitters were used, mounted on brass stands about 6ft. above each side of the platform, and connected in multiple arc. In connection with the transmitters, Bennett's iron cells were used, each transmitter having two of what are called "red" type connected in multiple arc. An ordinary G.P. covered No. 18 copper conductor was used to connect the instruments with about a dozen of the company's subscribers.

BROMINE AS A DEPOLARISING AGENT.—The depolarisation of the negative pole in an electric cell by the direct combination of the hydrogen evolved with oxygen produced by the decomposition of higher oxides or their derivations suggested to Mr. Koosen the use of bromine as one of the elements of a

Digitized by Google

constant galvanic cell of strong E.M.F. The cell thus constructed consists of a glass vessel, narrowed at the lower extremity, into which is poured the bromine; on this rests a plate of clay, on which is placed a clay cell containing an amalgamated zinc cylinder. A platinum wire passes through the clay plate into the bromine. To complete the cell, the upper part of the apparatus is filled with dilute sulphuric acid, covered by a thin layer of petroleum to prevent the diffusion of the bromine into the atmosphere. The E.M.F. of the combination, zinc, dilute sulphuric acid, bromine solution, platinum, is 1·9 volt; by substituting carbon for platinum, this value is increased. Its internal resistance is, however, greater than Grove's or Bunsen's cell, but has the advantage of being constant for several months.

ELECTRICAL MEASURE.—It is said that by means of the new instrument of M. Louis Maiche, the "michrohm-mètre," infinitesmal resistances may be measured with perfect exactitude. The instrument consists of a horizontal magnetised needle, which is placed between two bobbins of absolutely equal resistance, their coils being parallel. The coils are wound in directions reverse to each other, so that their action upon the needle is neutralised, and it rests immobile. The resistance to be measured is placed in the circuit of one of the coils; this reduces the tension of the current flowing in that coil and diminishes its controlling influence upon the needle, which deviates from its former position. Equilibrium is then restored by adjusting the stronger coil with a micrometer screw, which is graduated and indicates the value of the displacement of the second bobbin. It is claimed that the action of the instrument is both simple and exact; not only eliminating all the possibilities of error due to the imperfect contacts sometimes found in the Wheatstone bridge, but registering with accuracy such resistances as $\frac{1}{2000}$ of an ohm.

A SCIENTIFIC SUICIDE.—Of all the applications of electricity, there are but few which do not add to the general comfort, and tend to promote the welfare of our fellow creatures. Unscrupulous individuals have, from time to time, employed that useful agent for the furtherance of their designs upon human life and property, and others, not electricians, have dilated upon its peculiar fitness for the office of public executioner. *O tempora, O mores!* However, if no one puts electricity to a baser use than M. Paul Thiébault, who investigated the properties of high tension currents, with some inconvenience to himself, the world would not have to mourn the loss of any of those qualities which, in man, tend to ameliorate the condition of mankind. M. Paul Thiébault, aged 30 years, married, without children, has been struck dead by the current generated by the electric light apparatus at the works of M. Chertemps, in Paris. The result of the inquest showed that the deceased had entered the room on the first floor where the apparatus was at work, and had voluntarily and deliberately taken hold of the conducting wires; receiving a shock that killed him instantaneously.

ELECTRIC LIGHT WANTED AT EXETER.—The Corporation of Exeter purpose lighting by electricity an asylum now in course of erection. The asylum will be constructed to accommodate at present 300 patients, with provision for extension. Particulars of its dimensions and the ground plan of the building can be seen at the office of the architect, Mr. R. Stark Wilkinson, 14, Furnival's-inn, London, or Post Office-chambers, Queen-street, Exeter. Schemes and specifications are wanted for lighting the building; and tenders for (*a*) the first cost of installation, and (*b*) maintaining and working the scheme, recommended for a term of seven years, at a fixed sum per annum, are invited, but all tenders for installation only must state the probable annual cost of maintenance and working. Schemes and specifications must be accompanied by a tender for carrying out the work. The corporation will not pledge themselves to accept any tender, and they reserve the right to accept a tender for installation while they may reject the tender for maintenance and working; and no payment will be made for schemes or tenders. Sealed tenders must be sent to the town clerk, No. 15, Bedford-circus, Exeter, on or before the 1st May.

ELECTRIC LIGHTING CENTRAL STATION.—The installation at the Grosvenor Gallery is of far larger proportions than originally contemplated. Steam power of over 600 indicated horse-power will be supplied, while the dynamos made by Messrs. Siemens Bros. and Co. are the largest yet turned out by that firm. An excavation of nearly 600 square feet is being made under the Grosvenor-buildings, and in this space the machinery will be placed. Messrs. Gaulard and Gibbs's new type of secondary generators will be employed. About 5,000 lamps are being let out at a rental which, while paying the company who have taken the matter in hand, is accepted by those who desire the new illuminant. A temporary installation in Bond-street is now supplying about 250 incandescent lamps upon the secondary generator system in order to test its capabilities, and, so far, the result has been more than satisfactory; the current being perfectly under control. The whole of the arrangements, engineering and electrical, are being carried out on behalf of Sir Coutts Lindsay and Co. by Messrs. Mackenzie and Brougham, of 15, Great George-street, Westminster, who are the engineers to the undertaking. The work is to be completed in two or three months.

ELECTRIC SEARCH BOAT.—A craft, propelled by electricity, swift, silent, invisible in the dark, and easily managed by one man, undoubtedly possesses great advantages over the noisy steam-launch for the purpose of patrolling the Thames; and Messrs. Stevenson and Smith are to be commended, not only for their idea, but for the efficient means they have taken to put that idea before the authorities and the public. With the assistance of the Electrical Power Storage Company and Mr. Reckenzaun, a boat has been fitted up with a number of accumulators containing electricity sufficient to propel it at a considerable speed for several hours, and to supply a powerful search-light ready for instant use. A trial of the craft in question took place the other evening, and the experiment was to be tried again on the evening of Thursday, the 26th. The boat is 25ft. in length, with a beam of 5ft. 6in., and contains in a box running fore and aft 50 accumulators, weighing 40lb. each, which hold sufficient electricity to propel the boat at a speed of about eight miles an hour for four hours, or, if the arc light be used the whole time, for about an hour and a half less. This lamp, which is placed in the head of the boat, is of 3,000-candle-power, and its rays can be easily turned in various directions. By its aid objects on the water could be discerned at a distance of from 200 to 300 yards.

THE TELEGRAPH AND THE WAR.—The statement which recently came to hand from the Soudan that the Mahdi had executed two spies in consequence of information as to their doings having reached him through English newspapers, has again drawn attention to the mischievous uses to which the telegraph may be subjected at the hands of indiscreet newspaper correspondents. It is stated on good authority that whatever is telegraphed from the Soudan to England finds its way back again to the Mahdi's emissaries in a remarkably short space of time, and the execution of these two useful agents of ours seems to confirm the assertion. We had understood that Lord Wolseley, more than any other English general, was particularly watchful in

Digitized by Google

his censorship of "Our Special Correspondents'" telegrams; but either his vigilance has slackened or the newspaper men somehow manage to elude it. Otherwise there would not have appeared in print at the beginning of this week a description of Captain Wardrop's exploit, the publication of which, say next year, would have redounded to his credit not less than its trumpeting just now. It is probably the last time that trick can be played; and, what is perhaps of more consequence to the safety of the little band at Abu Klea, the Arabs now know that the supposed army of relief was not an army at all, and may renew their attacks. It is such gross and utterly needless revelations as these which bring the telegraph into discredit.

THE ELECTRIC LIGHT.—The installation at the Ferney Mills, Todmorden, comprising a 21-unit Crompton wrought-iron machine and 268 lamps, seems to give unqualified satisfaction. The light has been in operation for about three months, and is thus favourably reported upon by Mr. Crabtree, the owner of the mills in question:—"With respect to the cost of working—Power: We had plenty of surplus power, and as the result of an extremely careful test, made under conditions as nearly as possible parallel, we found that in four hours' working of the whole 268 lamps we only used 1½cwt. more coal than in four hours without the light, or less for power than 1½d. per hour for the whole 268 lights. Dynamo: This does not appear to be in any way depreciated; it seems as good as when it came, and the brushes are very little worn; it would seem as if the cost of renewals would be small indeed. Attendance: Including oiling, stopping and starting the dynamo, and the weekly cleaning of lamps, we find that less time is taken up than would be with gas." Mr. Barker, of Hebden Bridge, also reports that:—"The electric lighting plant (Crompton-Bürgin dynamo and Swan incandescent lamps) fitted in our clothing factory at May Royd is giving every satisfaction. We get the motive power from an ordinary breast waterwheel, which produces a very steady light. One of our warehousemen attends to the whole plant, spending on an average under thirty minutes per day. We may say that, although the premises are rather extensive and that we have 100 lamps, we can light the whole in less than two minutes from opening the doors."

ELECTRICAL RESISTANCE OF BISMUTH.—In a note to the French Academy of Science, M. Hurion gave an account of his experiments for determining the fact pointed out by Professor Righi, that the electrical resistance of bismuth increases when it is placed in a magnetic field. He asks if the variation of resistance noticed does not depend on the mechanical action exerted by the electro-magnet on the bismuth, and he seeks to estimate this action. A small bismuth plate, carried by a light wood frame with concave mirror, was suspended by a platinum wire. A copper ball, attached to the under side of the wood frame, served to stretch the wire, the upper part of which might be twisted to any angle, capable of being read correct, within a second, on a graduated circle. At the height of the mirror was a transparent and divided rule, on which was thrown a reflection, permitting of estimating, with the same nearness of approximation, the angular displacement of the wood frame. The bismuth plate, placed between the poles of the electro-magnet, was brought to equilibrium without any torsion of the wire, and then displaced to a certain angle, when the torsion corresponding to the angle was measured. Experience has shown that, for small angles, the torsion was proportional to the displacement, the ratio of the first quantity to the second being taken as a measure of the mechanical action sought. The experiments proved that the variation of resistance is appreciably proportional to the mechanical action exerted by the electro-magnet on the bismuth plate, while the curves of the two quantities present the greatest analogy. Professor Righi, who has devoted much attention to the changes which occur in the electrical resistance of bismuth at different temperatures, obtained a series of precise results. According to him, the electrical resistance of the bismuth of commerce is increased by the action of heat between certain limits of temperature and diminished between others. The curve of this variation, and of the different results obtained, are stated at length in the memoir published at Rome. The professor has also studied the influence of magnesium on this substance, and has found that the resistance increases under the influence of magnetism as much in pure bismuth as in the bismuth of commerce.

MODIFICATION IN THE SPARK OF INDUCTION COILS.—In a paper lately brought before the French Academy, M. Eugéne Demarçay points out certain modifications with the induction coil, for rendering its use easier and more practical in spectral analysis. The source of light universally used is the spark of very high potential, from a coil with a long and fine induction wire. This special construction is necessary in the case of M. Lecocq's experiments, owing to the fact that the liquid opposes a resistance impossible to overcome in the case of sparks with a slight potential. Employed in its original state this spark does not afford spectra capable of being utilised for bodies when it is desirable that they should have no appreciable chemical reaction. Moreover, the great part of those who have wished to obtain bands for these bodies have had recourse to the same induction coil by adding to it a condensing battery of greater or less power. Besides, it cannot be dispensed with when metallic electrodes of short interpolar distances are used to produce spectra, the spark otherwise becoming quite insignificant. But a considerable drawback to this process arises from the presence in the *spectrum* of secondary bands from the air and of bands from the electrodes. The *spectrum* of the air especially has a brightness much greater than that of the metallic bands present. This drawback, added to the separation necessitated by the *spectrum* of the electrodes, renders long and difficult an examination which, if it is not rapid and simple, is without practical value for the chemist. All these difficulties disappear at once, and a spark is obtained which gives no trace of secondary bands of the air and rarely slight traces of nebulous primary bands of nitrogen and bands of the electrodes, by using the spark of a coil with thick and short induction wire. This spark has a temperature sufficiently high to easily give *spectra* of all the elements known. The coil constructed for this purpose yields a spark of 5 millimetres only, under the action of a battery of 6 or 9 bichromate elements (zincs, 10 by 16 centimetres), two or three in *surface* and three in series. The coil has 115 centimetres in internal diameter, and a length of 23 centimetres. The induction wire, 1 millimetre in diameter, weighs 1·32 kilogramme, and is wound on two ranges. The induced wire, 1 millimetre in diameter, weighs 3·4 kilogrammes. The bundle of soft iron wire, 27 millimetres in diameter, weighs 680 grammes. Lastly, the condenser of the inducing current is threefold that of the condenser usually placed on such coils. It should still be insufficient, because the spark of the extra current is very appreciable. The spark produced is 5 millimetres long; and its *aureola*, at least 3 millimetres for 6 elements, is almost silent, and becomes brilliant when sufficiently shortened. It gives with brilliancy, especially when short, the *spectrum* of the electrodes and traces, scarcely visible, of the primary nebulous bands of the air, which even disappear entirely in most cases.

ALTERNATING CURRENTS.

BY THOMAS H. BLAKESLEY, M.A., M. INST. C.E.

(CONTINUED FROM PAGE 287.)

CONDENSER.

In applying the geometrical method to the representation of the effects upon the carrying power of a circuit of electric capacity it will be necessary to bear in mind carefully what is meant by capacity. An arrangement is said to possess capacity when the arrival and accumulation of a certain finite quantity of electricity is necessary before it can exhibit a rise in potential. If the rise in the potential is proportional to the net arrival of electricity, the capacity of the condenser is said to be constant, and is measured by that amount of electricity necessary for a rise of potential of a unit amount. It has been denied that a voltameter is a condenser, but without justice. The arrival and accumulation of electricity is necessary before the electrodes of the voltameter exhibit difference of potential. When this takes place it is accompanied, not perhaps by what is sometimes understood as a static charge, but by a decomposition of the fluid, and an annexation, incipient or otherwise, by the electrodes of the products of the electrolysis. In an incipient condition, with which in the question of alternations we should have to deal, it is not certain how the quantity of electricity which has reached the voltameter is connected with the difference of potential exhibited by the electrodes. That is to say, the condenser of this form may not have a constant capacity, and therefore might disturb the harmonic nature of the alternations, even when the variation of the impressed electromotive force was truly harmonic. But with the more usual form of condenser, where there exists a constant capacity, there will be, indeed, upon its introduction into the system, a rearrangement of the values of the current in different parts, but each will remain harmonic in character.

Suppose the straight lines A B, B C, C D, &c., being the consecutive sides of an unclosed polygon, represent the values of *currents* conveying electricity harmonically to and from a point, with the same period of variation.

Then, since the rate of arrival of electricity is represented at any instant by the sum of the projections of the individual lines upon some fixed line, and the sum of such projections is equal to the projection of the line joining A D, the extreme points, therefore the arrival of electricity will be that due to *one* current of the value A D.

Thus, however many harmonic currents of the same period are flowing into and out of a condenser, and whatever their differences of phase, their effect in charging that condenser will be that due to *one harmonic current* of the same period, and in a certain determinate phase as regards the actual currents. This current may be called the effective current.

It will be necessary to consider, therefore, the effect upon a condenser of constant capacity of the arrival of electricity at a rate undergoing harmonic variation, for that rate is the effective current.

While the current is positive the charge is always increasing; and, *vice versâ*, the charge of the condenser is always decreasing when the current flows away from the condenser. Hence the charge will be greatest when the current is changing from positive to negative through the value zero, and least when the current is changing from negative to positive through the value zero.

Let us take this latter point to start from, and consider what the accumulation of electricity will be in a given time t. If T is half the period, the angle through which the line representing the current will revolve in time t is equal $t\frac{\pi}{T}$. Call this angle α. Let θ represent any angle which the line has traversed between zero and α by a given point of time.

Then if c is the maximum value of the current, $c \sin\theta$ will be its value at the particular point of time considered. Now, supposing we knew the average value of this current between the values of θ, zero and α, we should only have to multiply this average value into the time t to find the value of the electrical accumulation. The factor c is constant, and therefore the accumulation depends upon the average value of $\sin\theta$ between 0 and α.

The following subsidiary proposition is a mode of finding the value required without the use of the integral calculus.

PROPOSITION II.

To find the average value of $\sin\theta$ and $\cos\theta$ when θ varies from 0 to α uniformly

Let $S(\alpha)$, $C(\alpha)$, represent respectively the average values of $\sin\theta$ and $\cos\theta$, when θ varies uniformly from 0 to α.

Now, the cosine of any angle between 0 and α may be expressed by $\cos\left(\frac{\alpha}{2}+\phi\right)$ or $\cos\left(\frac{\alpha}{2}-\phi\right)$; where ϕ may have all values from 0 to $\frac{\alpha}{2}$.

Therefore all the values of θ may be grouped into a number of pairs, represented by $\left(\frac{\alpha}{2}+\phi\right)$ and $\left(\frac{\alpha}{2}-\phi\right)$; where ϕ varies from 0 to $\frac{\alpha}{2}$.

Now, $$\cos\left(\frac{\alpha}{2}+\phi\right)=\cos\frac{\alpha}{2}\cos\phi-\sin\frac{\alpha}{2}\sin\phi$$

and $$\cos\left(\frac{\alpha}{2}-\phi\right)=\cos\frac{\alpha}{2}\cos\phi+\sin\frac{\alpha}{2}\sin\phi.$$

Therefore, the average value of the pair of cosines, $\cos\left(\frac{\alpha}{2}+\phi\right)$ and $\cos\left(\frac{\alpha}{2}-\phi\right)$ is $\cos\frac{\alpha}{2}\cos\phi$.

Thus the average value of $\cos\theta$, where θ varies from 0 to α uniformly, depends upon the average value of $\cos\phi$, where ϕ varies uniformly from 0 to $\frac{\alpha}{2}$, as in the following expression:—

$$C(\alpha)=\cos\frac{\alpha}{2}C\left(\frac{\alpha}{2}\right).$$

Similarly $$C\left(\frac{\alpha}{2}\right)=\cos\frac{\alpha}{4}C\left(\frac{\alpha}{4}\right).$$

Therefore $$C(\alpha)=\cos\frac{\alpha}{2}\cos\frac{\alpha}{4}\cos\frac{\alpha}{8}\ldots\ldots\cos\frac{\alpha}{2^n}C\left(\frac{\alpha}{2^n}\right).$$

The angle $\frac{\alpha}{2^n}$ becomes indefinitely small when n is made infinitely large, and evidently the average value of the cosine of a very small angle approaches unity, therefore $C\left(\frac{\alpha}{2^n}\right)$ is equal to unity when n is made infinitely great.

Therefore $$C(\alpha)=\cos\frac{\alpha}{2}\cos\frac{\alpha}{4}\cos\frac{\alpha}{8}\ldots.\ \textit{ad infinitum}.$$

But by ordinary trigonometry

$$\sin\alpha=2\cos\frac{\alpha}{2}.\sin\frac{\alpha}{2}$$

$$=2^2\cos\frac{\alpha}{2}.\cos\frac{\alpha}{4}.\sin\frac{\alpha}{4}$$

$$=\alpha.\frac{2^n}{\alpha}.\cos\frac{\alpha}{2}\cos\frac{\alpha}{4}\cos\frac{\alpha}{8}\ldots\ldots\cos\frac{\alpha}{2^n}\sin\frac{\alpha}{2^n}$$

$$=\alpha.\cos\frac{\alpha}{2}\cos\frac{\alpha}{4}\cos\frac{\alpha}{8}\ldots.\cos\frac{\alpha}{2^n}\left(\frac{\sin\frac{\alpha}{2^n}}{\frac{\alpha}{2^n}}\right)$$

and when n is infinitely larger,

$$\frac{\sin\frac{\alpha}{2^n}}{\frac{\alpha}{2^n}}=1.$$

Therefore, $$\sin\alpha=\alpha\cos\frac{\alpha}{2}\cos\frac{\alpha}{4}\cos\frac{\alpha}{8}\ldots\ldots\ \textit{ad infinitum},$$

Digitized by Google

and hence

$$C(a) = \frac{\sin a}{a} \quad \ldots\ldots\ldots\ldots \quad (\alpha)$$

or the average value of cos θ, when θ varies uniformly between 0 and a, is $\frac{\sin a}{a}$.

Similarly

$$\sin\left(\frac{a}{2} + \phi\right) = \sin\frac{a}{2}\cos\phi + \cos\frac{a}{2}\sin\phi,$$

and

$$\sin\left(\frac{a}{2} - \phi\right) = \sin\frac{a}{2}\cos\phi - \cos\frac{a}{2}\sin\phi.$$

Therefore, the average value of the pair of sines, $\sin\left(\frac{a}{2}+\phi\right)$ and $\sin\left(\frac{a}{2}-\phi\right)$ is $\sin\frac{a}{2}\cos\phi$.

Thus the average value of $\sin\theta$, when θ varies from 0 to a uniformly, depends upon the average value cos ϕ, where ϕ varies from 0 to $\frac{a}{2}$, as in the following expression :—

$$S(a) = \sin\frac{a}{2} C\left(\frac{a}{2}\right).$$

But by the former portion of the proposition the value of $C\left(\frac{a}{2}\right)$ has already been determined (α) to be

$$\frac{\sin\frac{a}{2}}{\frac{a}{2}}$$

Therefore

$$S(a) = \frac{\sin^2\frac{a}{2}}{\frac{a}{2}} = \frac{1-\cos a}{a}; \quad \ldots\ldots \quad (\beta)$$

that is to say, the average value of $\sin\theta$, when θ varies from 0 to a, is

$$\frac{1-\cos a}{a}.$$

We can now deal with the electric problem, for the supply of electricity given by the harmonic current in a time t dating from the zero value of the current will be $tc\,S\left(\frac{t\pi}{T}\right)$

$$\text{or } tc \times \frac{1-\cos\frac{t\pi}{T}}{\frac{t\pi}{T}} = \frac{Tc}{\pi}\left(1-\cos\frac{t\pi}{T}\right) = \frac{Tc}{\pi} - \frac{Tc}{\pi}\sin\left(\frac{\pi}{2} - \frac{t\pi}{T}\right) \quad \ldots \quad (\gamma)$$

and the total supply during one half period is therefore equal to $\frac{2Tc}{\pi}$, which is the value of the above expression when t is equal to T. During the second half period this quantity of electricity is abstracted.

During the first quarter period the supply will be $\frac{Tc}{\pi}$, or half the entire quantity, and as it is convenient always to measure from a mean value of any harmonically varying magnitude, we may consider $\frac{Tc}{\pi}$ to be the addition or withdrawal of electricity in any of the quarter periods, to or from the mean value.

The expression (γ) shows that the variation in the supply is harmonic, and differs by a quarter period in phase from that of the current in the direction of retardation.

Hence, if the condenser be one whose capacity is constant the potential difference of its plates will undergo harmonic variation, and in a diagram of electromotive forces will be drawn at right angles to any line which is in the same phase as the effective current into the condenser, in the direction of retardation. If C is the capacity of the condenser, the amplitude of the difference of potential of its plates will be $\frac{1}{C}\frac{Tc}{\pi}$ which E.M.F. will occur when the effective current is changing its direction.

We shall next consider the effect of connecting two points of a circuit with the plates of a condenser.

(TO BE CONTINUED.)

MATHER AND PLATT'S PATENT GEAR.

FOR DRIVING DYNAMOS ON BOARD SHIP, AND IN OTHER CASES WHERE THE SPACE IS CONFINED.

The first sketch shows an arrangement for driving a dynamo by helical wheel gearing.

The engine is one of Mather and Platt's usual double cylinder diagonal engines, with cylinders 8in. diameter by 10in. stroke. As will be seen, the bed is of a rigid form, and suitable for running at a high speed with great steadiness. The crank is of the ordinary double sweep form, and the crosshead and slides are cylindrical. The engine is fitted with the well-known Mather and Platt patent metallic piston. The valves are of the slide valve type, and the engine is regulated by a Pickering governor attached to the steam supply pipe, and driven from the crank shaft by a pair of beveled wheels.

The engine has long brass bearings, the crank shaft bearing on the driving side being made extra long.

The fly-wheel is formed into an internal spur wheel with double helical teeth, the boss of the wheel being turned and let into the crank shaft bearing, which is bored out to receive it. By this means the strain on the crank shaft is one of torsion only, and the wheels are more rigid and kept in their proper relative positions, so that the teeth are always in full gear. This wheel gears with a pinion keyed on a shaft carried through the engine bed. This shaft is coupled direct to the dynamo shaft by means of a flexible coupling. It will thus be seen that any slight irregularity or jar in the engine or first pair of wheels is lost in the shaft and coupling before reaching the revolving armature of the dynamo, which is of the greatest importance on account of its weight and speed, and from the fact that any springing of the shaft, however small, is intensified by the unequal magnetic stresses which are at once brought into action. The wheels of the engine and dynamo are in the proportion of 6 to 1, the former making 175 revolutions per minute.

This method of driving possesses great and obvious advantages over any kind of friction gear. All devices for driving by friction gear necessitate more or less delicate and elaborate arrangements for regulating the pressure between the friction surface, and these require constant attention and adjustment in order to follow up the wear. There is also the loss of power in friction, which even with plane surfaces is very considerable, and still greater when V grooves are employed. In an internal wheel the friction is less than in ordinary spur gearing, as the stresses are more nearly exactly tangential to the pitch line of the wheels. There is very little wear in the wheels, and no parts requiring replacement, which is necessarily the case with the friction pinion. When the wheels are once set they require no further adjustment or attention. By using double helical teeth in connection with an internal wheel the number of teeth in gear at any instant is increased, so that a finer pitch can be used, which reduces the noise so as to be almost unnoticeable.

The engine is shown in the drawing driving one of Mather and Platt's new compound wound dynamos for 150-200 twenty candle-power lamps, 100 volts E.M.F. at 1,050 revolutions per minute, of the same type as above described.

The second sketch illustrates the same sytem of driving applied to the same dynamo, the engine in this case being one of Mather and Platt's single cylinder oblique engines. The cylinder is 10in. diameter by 12in. stroke. The wheels are the same proportion as before, viz., 6 to 1, and the engine makes 175 revolutions per minute. The crank shaft is of the best hammered scrap, and carried in long adjustable brass

Digitized by Google

bearings. The connecting rod is also of wrought iron, having adjustable brasses at both ends, and adjusted to the crosshead by a steel pin. The slide is of cast iron, and bored to suit the circular cross head. The engine is fitted with a Mather and Platt patent piston, with steel piston rod, and the regulation is effected by a Pickering governor, driven by a strap from the crank shaft.

The driving is effected through a shaft and flexible coupling, just as in the previous arrangement.

The third sketch illustrates an arrangement of short-belt driving applied to the same dynamo and diagonal engine above described. The engine is just as before, except that in the place of the helical wheel on the engine the fly-wheel is turned suitable for belt driving.

The proportion of the wheels and the speed of the engine are the same as before.

In order to give the strap more grip on the pulley of the dynamo, by giving it more surface and at the same time taking up the sag in the belt, a very effective arrangement is used, and which is clearly shown in the drawings. This consists of an arm which swivels on the filbore of the dynamo shaft, and at the end carries a pulley riding loose on a stud. The lower end of the arm is formed into a wheel quadrant, which gears into a worm carried on a spindle at the end of the bed of the dynamo. By turning a hand-wheel keyed on the end of the worm spindle the arm, and with it the pulley, is raised or lowered, and thus the strap wrapped less or more round the pulley as required, giving a neat and effective strap driving in a small space. It is evident that a long strap is unnecessary, and it is obvious that a great saving is effected in belting alone. For in this case we have a belt which may be less than half the length of a belt as generally used doing the same work, but with the advantage of putting less strain on the driving side of the strap, and also on the dynamo shaft, by giving more pulley surface to the belt.

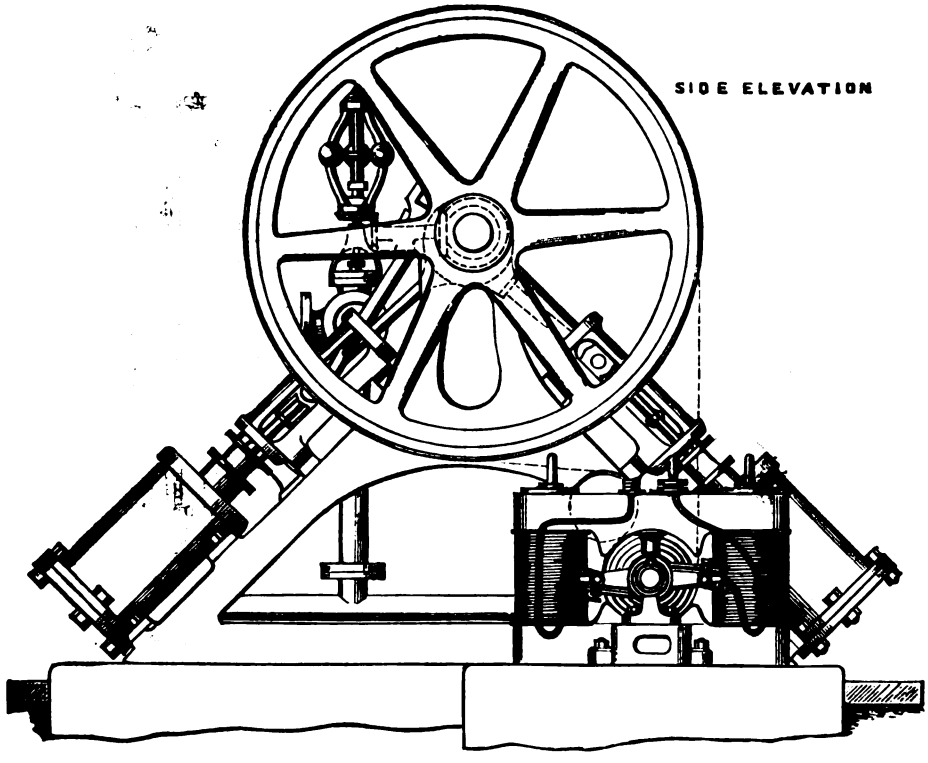

FIG. 1.

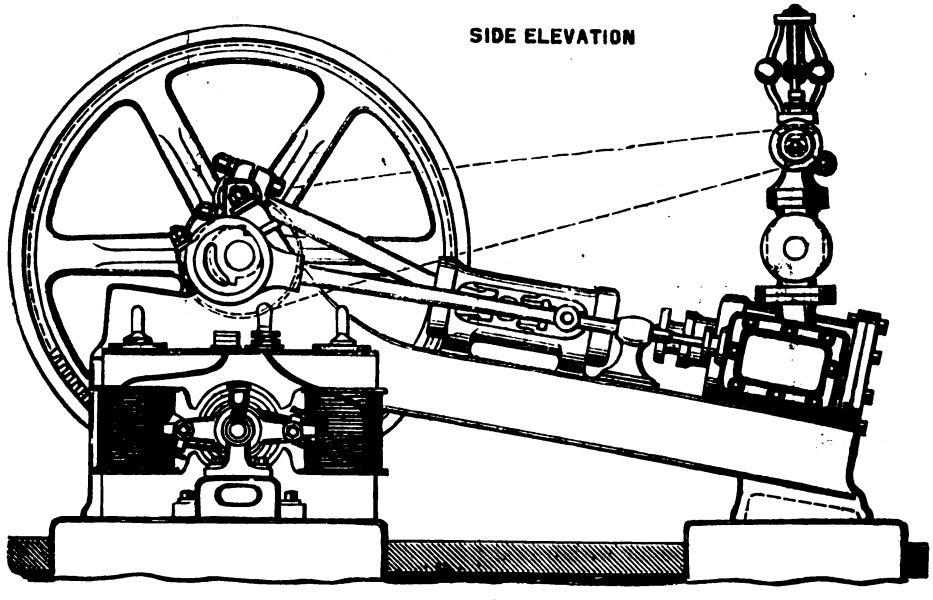

FIG 2

Digitized by Google

The fourth drawing shows the above arrangement of belt-driving applied to the same dynamo, but using the single cylinder engine before described in place of the diagonal engine. The advantages of these methods of driving are not confined to ship lighting. In mills and workshops it is often desirable to place the dynamo in the engine room, so that it may require no further attendance than from the man in charge of the main engines. The space is usually in such cases very confined, excluding the possibility of driving by a long belt. The method last described has been very effectively employed by Messrs. Mather and Platt in the installation in connection with the Theatre Royal and Comedy Theatre in Manchester for driving two 250-lamp Edison-Hopkinson dynamos. It may also be advantageously used with gas engines for house lighting, as it enables the engine and dynamo to be fixed on a single bed plate.

ELECTRO-CHEMICAL EQUIVALENTS.

M. E. Hospitalier terminates an article in *L'Electricien* on electro-chemical equivalents, as follows:—Faraday's and Thomson's laws sum up all the facts at present known about electrolysis. Let us be content with them and apply them, without introducing the notion of *thermic characteristics* and *thermo-electric coefficients*, the least inconvenience of which is to introduce non-homogeneous equations into the calculation, thus rendering verification impossible. We have already deprecated this view of electro-chemical phenomena, and protested against expressing in *calories* the electromotive force of batteries, which introduces a confusion of ideas to be combated so long as it exists. A *calorie* is of the same nature as a unit of work, and can therefore not be compared with electromotive force; and it is no more correct to express the latter in *calories* than to speak of an intensity of current being equal to a quantity of electricity, or a unit of work to one of power, as has been done by the reformer of Faraday's and Thomson's laws.

THE POSTMASTER-GENERAL ON GAMBLING.

The present Government has been eulogised as a Ministry composed of all the virtues, and until recently we all believed it. Perhaps it was owing to the consciousness of something lacking in their title to this encomium, rather than to any scepticism on the part of the British public, that a couple of brand new virtues to the round dozen which illuminated the councils in Downing-street has lately been added. Any way, one noble lord has come in who holds convenient views about Providence and the fall of Khartoum; whilst the new Postmaster-General carries with him an exemplary horror of gambling. Neither of these gentlemen is expected to button-hole his colleagues on the subject of his favourite cult. Were this the case, Providence, in connection with the contingent fall of Berber into British hands, might be an inconvenient topic for some of the graver Ministers; and for some others of a gayer turn of mind Mr. Shaw-Lefevre's notions about betting might be deemed out of place. The beauty of the arrangement, as a whole, it will be seen, is that the virtues are represented not individually but collectively, without imposing an irksome quantity upon any one in particular.

Mr. Shaw-Lefevre, we say, has expressed a horror of gambling. We do not mean of gambling in politics—a virtue which for aught we know has yet to be adequately individualised in the Cabinet circle—but gambling at cards and on horse races. No sooner did he assume his new rank than the public were informed through the newspapers that the new Postmaster-General had issued an edict against gambling—nay more, had demonstrated his sincerity by summarily discharging one postal officer and reducing several subordinates for holding views on this subject which were considered heterodox. It is due to him to remark that he "has felt constrained" to do this; and we all know that from an orthodox point of view when we "feel constrained" to do this or that, how pained we are to have to do it, and how proud of having overcome our reluctance. We do not wish to say a word in defence of the culprits, whose offence seems to have been that they played at cards and betted on horses for stakes far beyond what the players could afford, which was very foolish of them; and did this on official premises, which was still more foolish; and during official hours, which was decidedly culpable. But we do hope that these erring young men—for they must have been young—had some better warning of their misconduct than is implied in the public notice we are referring to. "The Postmaster-General deems it his duty to make these punishments known by way of warning, as, in the case of Post Office servants, he regards gambling in any form as a most serious offence," &c.—language which reads like punishing first and warning afterwards. How could these inexperienced subordinates, who studied the sporting rather than the political columns of their daily paper—how could they be supposed to know that Mr. Fawcett's successor had imported a new virtue into the Department?

For the purpose of enforcing his decision, and apparently to justify it, the Postmaster-General reproduces a notice issued nearly seven years ago; and therefore at a period when the loftier virtues were not officially represented as at present. This fact is betrayed in the document itself, which is in the main a matter of fact statement of a real evil then on the increase, and one that it was necessary to discourage. It ends as follows:—"Any servant of the Department who shall hereafter be concerned in betting will render himself liable to dismissal." This is business-like; and the reasons assigned for it are such as would justify any large employer of labour in using similar threats. No doubt it is in the interests of the servants themselves as well as in those of the public that postal and telegraph officers should be forbidden to entangle themselves in betting.

But, granting all this, it does seem to us rather harsh that a whole body of public servants should be implicitly stigmatised as "gamblers" because at one time some telegraphic information got into wrong hands—through the instrumentality of boy messengers if we recollect rightly—or because some sorters or letter carriers at one particular office have cultivated a fancy for card playing and its near relation horse racing. The divulging of telegrams is, we imagine, extremely rare, for we seldom hear of such offences; whilst pilfering from letters is unhappily of frequent occurrence. But in any case such breaches of faith by telegraph servants have nothing to do with betting inside the Department. It is outside betting that holds out this temptation; and outside betting is what the Department does not discourage—rather the contrary, promoting it by affording facilities which practically operate as an encouragement.

Perhaps it was some faint compunction on this score that induced the present Postmaster-General to slip that parenthetical qualification into the minatory paragraph we have quoted above, "as, in the case of Post Office servants, he regards gambling in any form as, &c." The head of a department that derives a large revenue from gambling in its most prevalent form, and increases that line of business to the utmost of its ability, cannot afford to be virtuous indiscriminately. For this very reason we would beg of him that the "exemplary manner" in which he threatens to put down "gambling in any form" may be an example of mercy not

Digitized by Google

less than of vigour. From the nature of their occupation, and the one-sided laxity of the Department, a large number of telegraphists are necessarily thrown in close relations with the betting fraternity, and become exceptionally well informed on racing topics. Not that betting messages afford any valuable information for would-be gamblers; that, we should say, is an illusion. But just as Stock Exchange telegraph offices must acquire an exceptional knowledge of the markets, so do offices in racing districts with regard to the Turf. Whether this is a temptation to betting we are not in a position to say; but if it is, the temptation is inherent to the employment, and is rather a misfortune for the *employé* than a disadvantage to the employer. By all means, if public interests demand it, put down "gambling" on the premises—and off them, too, if possible. But let us call things by their right names. It may be expedient and necessary to forbid to postal and telegraph servants what other people may do without reproach; but there is no good in using hard words about it, or assuming virtuous airs which nobody, except with political faith, believes in.

CORRESPONDENCE.

PERSONAL SAFETY AND ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As Mr. Walker's original inquiry for further information about the evidence which transpired at the inquest on the accident at the Healtheries has not been answered, I am glad to be able to give a few details, which may also be of use to Mr. Sennet.

The only fairly correct report was the one which appeared in your columns. I have not got this to refer to, but I recollect most of the points very distinctly.

The only eye-witness described most explicitly that one hand (the left) was on the brush, and that the other "was as though he were feeling round" under the bearing, gradually approaching the lower part of the commutator and the lower brush. The witness understood enough of the question to be struck at the man's action, and watched him with surprise, and doubtless would have spoken in another instant.

The first result was a sudden contraction of the arms and chest, and if there had been hold for the fingers they would probably have closed on some part of the machine. He undoubtedly received the full volts (about 1,200). The left hand broke contact first as he began to fall, and on the tip of the finger of that hand was a slight scar, as though burned by a hot wire.

The interesting part of the evidence was most carefully taken by the coroner, Mr. Braxton Hicks, from the house surgeon, Mr. Bloxham, and I have little doubt that both of these gentlemen, if personally approached, would corroborate my recollections. No shorthand reporter was present, but the coroner took very full notes.

The physiological and pathological evidence was as follows:—First a spasmodic contraction of the arms and chest—in fact of the muscles in the path of the current—described by a gesture by the witness which corresponded exactly to that which is tolerably familiar to those who occasionally receive an accidental shock. The man fell away from the dynamo, collapsed, rolled, and became unconscious—he was probably dead before he fell; a slight mucus foam appeared at the lips. The body speedily became discoloured, rigour never set in, and this, coupled with the fact that the blood never coagulated, is in accordance with several authentic records, but at variance with Dr. Stone's suggestion.

All the blood vessels in the path of the current were highly congested, more so in the chest than in the back. The brain and its membranes were normal, as were all other organs, but the heart was *empty*. The state of the venæ cavæ and pulmonary vein was not described, and it must be assumed that these were not congested. Mr. Bloxham informed me that there was no perceptible evolution of gas or other change in the tissues of the finger tips. It would appear that the mere "shock" is quite enough to account for death; and of the other causes, the complete evacuation of the heart seems to be the most important, this being produced by the general tetanus of the thorax. It appears possible that the well-known process of artificial respiration might be tried with a view of starting the heart's action if the shock had not produced other fatal results.—Yours, &c.,

ALEX. P. TROTTER.

Ball Green Works, Halifax, 19th February, 1885.

ELECTRO-MAGNETS.—MR. BOSANQUET'S LETTER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: This kind treatment is enough to gladden any unit's heart—and you must admit that units have hearts, or else why christen them? I have to thank Mr. Fricker for his letter, and especially I have to thank Mr. Bosanquet. The latter has given me the right sort of information, but, unfortunately, not enough of it. Since reading his letter I have been making experiments, because I have need to know how many ampere turns will saturate or nearly saturate a core of iron 5½in. long by 2¼in. diameter. I find it is in practice, with Bowling iron, between 5,000 and 6,000 ampere turns; according to Mr. Bosanquet's formula I make the figures come somewhere about 9,300. But I made the calculation very roughly. Is this because the magnet approaches the class of short and thick bars for which he doubts the applicability of the formulæ? If so, he would confer favours of great value if he would point out to practical men like myself wherein the modification may most likely lie, so as to give us some data to go upon.

I notice that in u, $\mathfrak{B}$ can vary greatly without much effect. For instance, if the sum of the sine terms becomes ·8, u only becomes 1,900; and consequently $\frac{l}{u}$, as the first term of ρ, does not seem to get that alteration we are accustomed (with short magnets as regards their diameters) to see.—Yours, &c.,

VOLT-AMPERE.

A FAILURE OF THE ELECTRIC LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should be obliged if you would insert the following letter in your journal. A little while ago you were enabled to chronicle the successful lighting by electricity of the parish church of Brixton, and for a few months the same was everything that could be desired; but now, oh dreadful hour! it has broken entirely down.

The sixty incandescent lamps appear to be arranged six in series, and consequently when one filament goes the other five are in darkness; likewise, as there appears to be no regulator of current, &c. (and I believe the four arcs are driven from the same engine), the remaining incandescents burst out with stronger light till another filament goes, and a series of disasters follow, which end in the parson closing his sermon, and suggesting the singing of a hymn while the gas is arranged.

Is it economy in the matter of leads the company study? Surely sixty amperes could be transmitted direct in a wire a very little larger than they are now using to a distance less than a quarter of a mile. The church paid a good sum for the fittings, and they expect a better return for their outlay than the piping, popping, and smoking exhibition they were treated to last Sunday week, causing a general disturbance, during which many people left the church.

Hundreds of people go home and tell everybody that the electric light is a complete failure. The question is, will other churches take it up while this penny-wise and pound-foolish game goes on? If this kind of lighting is to be more general in churches, the contractors must at least go sensibly to work—that is if they wish to brighten instead of ruin the reputation of this beautiful light.—Yours, &c.,

ONE OF THE CONGREGATION.

"PAPP" CHLORIDE OF IRON BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to the above battery I should like to call attention to the following paragraph which appears in the *earlier*, as well as the later, editions of "Watts's Electro-Metallurgy," § 69, p. 163:—

"A new constant battery has been suggested by Mr. A. Reynolds, in which a solution of per-chloride of iron is used as an exciting fluid, and metallic iron as the positive electrode."

I understand that this cell is claimed as a new invention, but I fail to see how it can be substantiated in the face of the above.—Yours, &c., A. T. B.

Bristol, 25th February.

ERRATUM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May I be permitted to correct an error which has inadvertently crept into my letter of last week? Instead of "40,000 cubic feet of air raised 8 degrees," I should have written "raised 4 degrees."—Yours, &c.,

A YOUNG ENGINEER.

THE MECHANICS OF ELECTROLYSIS.

BY A. BANDSEPT.

I.

In galvanic batteries, the separation of the constituents of the liquid is due to the differential attraction exerted by the electrodes on the elements of the bodies which are dissociated under the combined effect of this action and that of the re-agent. The elements become separated by a process analogous to diffusion; and the intensity with which the phenomenon manifests itself is in ratio to the transparency of the collector for the electricity evolved during combination, and its opacity for the more ponderable which contained the charges. This selection of the dissociated radicals is due to the form of the polar molecules and to the nature of their movements. Thus, in the ordinary example of the copper-zinc couple, the electromotive force derives its origin from the attraction of the zinc for the sulphuric radical of the acid. This radical, by its tendency to combine with the zinc, brings about the condensation of the molecule H_2SO_4, with elimination of the most subtle element, H, and formation of the new arrangement $ZnSO_4$. But, concurrently with this dissolution of the zinc, there is disengagement of heat, because when two bodies combine—that is to say, when they re-unite in a more perfect grouping the elements of which they are composed, the specific activity of the new system is brought within narrower limits, and a portion of the composing forces appears under the form of external motion; the acid penetrating the substance of the zinc gives rise to the production of hydrogen and heat. The nascent hydrogen absorbs heat in its turn, in order to become gas; so that the disengagement of this element implies the subtraction of an appreciable quantity of energy, both in primary and in secondary batteries, since there is always a molecular separation with electric action.

What has just been said of the various modes of motion, which accompany transformations of bodies in the case of electrolysis, applies equally to every other combination of elements of any order whatever. Energy enters into the constitution of all bodies. They all possess a certain specific quantity of motion, heat, light, and electricity, which determines the conditions of their actual state. If two or more bodies combine with considerable disengagement of heat, this only means that they form a very close union, and that the internal motion of their constituents is transformed, and extends appreciably beyond the narrow space occupied by the newly constituted body. All sudden diminution of the present limitation of a body is *necessarily* accompanied and compensated by an equivalent extension, which constitutes the reaction. This second phase of the double action consists in a particular mode of motion, for which the force *seems* to have the better of the material substratum. In the reciprocal action which takes place in all natural phenomena, one phase distributes itself over a *so much greater number of so much more minute particles*, as the intensity of the action-reaction is greater for a given period of time. Electricity becomes, therefore, a function of the ultimate particles of matter.

To determine the sort of actions which take place in electrolysis, it must not be regarded as causing the transfer of the material elements from one pole to the other. The hypothesis of Grotthus might rather be admitted, that is to say of actions propagating one another nearer and nearer, and consisting of combinations, ruptures and recombinations of molecules, from one to the other electrode. But this hypothesis does not give a complete idea of the manner in which the decomposition takes place; it does not say *why* the motion originates at the contact of the plates and the liquid, nor how the first separation of the elements takes place there, unless the supposition be admitted that this effect is solely due to the differential attraction created on the polar surfaces by the electric current. M. Clausius has, moreover, raised objections to this hypothesis, viz., that the successive decompositions and recompositions would necessitate a too great expenditure of energy, and cannot be simply attributed to the electro-positive and electro-negative properties of the radicals. It is, perhaps, this consideration which has led M. Clausius to his theory of the molecular agitation of bodies, and which has made him suppose that the elements of which the liquid electrolytes are composed often become separated and change partners, so that the current would have nothing more to do than to direct and classify them. This theory, then, constitutes the counterpart of that of Grotthus; and one might ask if it does not err by excess in the contrary direction.

The explanation of the mechanism of electrolysis becomes, perhaps, more satisfactory when the physical conditions of the molecular system under consideration are made to intervene. In that case it is readily understood how the impulse is given to the motion which is transmitted, nearer and nearer, in the liquid column separating the electrodes.

When the circuit is established, the molecule H^2SO^4—in the electrolysis of water—is dissociated; the large quantity of heat incorporated by the radicals, chiefly by the hydrogen, determining the expansion of the molecule. A new arrangement succeeds to the old grouping, in consequence of the direction given to the constituents under the combined effect of the shock of the expanded molecule against one of the electrodes, and of the affinity for the neighbouring body, the other plate. An ideal system of electrolysis is here supposed; and only the relative actions of one of the constituents is brought under consideration.

The conversion of current energy into internal motion of the liquid molecules is specially due to the volumetric properties of the hydrogen. The reducing power of this gas in the nascent state varies with the chemical reaction which has produced it. Now, the combination of the hydrogen with the oxygen disengaging a considerable quantity of heat, and its specific heat for an equal volume being relatively small, it follows that its capacity for *incorporation* is so much greater. The expansion undergone by the thermometrical substance—hydrogen in this case—has the effect of pressing the compound molecule against the surface of the electrode. This molecule becomes deformed in striking the surface; and the reaction exerted by the pressure is transmitted to the core H, which is drawn along in the direction of the current, and which passes by the polar opening, more or less retractile, caused by the flattening of the envelope SO. The molecular deformation which accompanies the separation of the radicals, and which facilitates their penetration into the following elements, is again partly due to the differential gyratory motion imparted to the two components during the transformation of the current into intermolecular energy. In fact, when a body consists of two or more elements differing in density, and which are relatively independent in their respective motions, the element which is the less dense becomes displaced less rapidly than the denser element; and the latter acquires the greater speed. The molecular envelope revolves, therefore, considerably quicker than the core; it becomes flattened towards the ends

Digitized by Google

of the axis of rotation, which is turned in the direction of the current; while the core practically retains the oblong form due to the *entrainement* (or drawing along) caused by the passage of the electricity into the interior of the molecule. While the envelope has a tendency to disentangle itself after the manner of a ring, the core affects the form of a hair or cilia, which facilitates its introduction into the neighbouring body. If, at this moment, the action of the current cease, the decomposition will be incomplete; for the tendency of one of the elements to approach the other increases in proportion as they are separated, and until their reciprocal influence be annihilated, in which case polarisation occurs.*

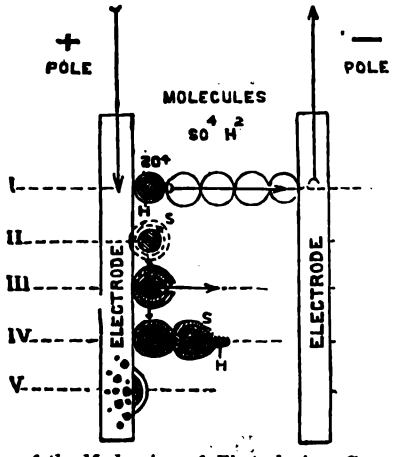

Diagram of the Mechanism of Electrolysis.—General Case.

I. Composite molecule H^2SO^4. II. Expansion by absorption of the energy of the current; shock against the positive and deformation of the molecule. III. Reaction on the core H; differential gyratory motion of the radicals H^2 and SO^4; separation of these elements. IV. Incorporation of H in the succeeding molecule by the polar opening of the covering, skin, or envelope of this molecule. V. Breaking down of the portion SO_4 thus forming the envelope of the first molecule, in consequence of the vacuum produced by the exit of H; elements of this envelope penetrating the polar surface. Disengagement of heat in consequence of this penetration.

This explanation, as will be seen, is only based upon the sole mechanical conditions of the system under consideration, and only examines the most elementary combinations that can be proposed for the formation of bodies, into the composition of which energy always enters. This latter gives them the special volume corresponding with a given temperature. Instead of the dance of molecules or inverted groupings of the preceding theories, without indication of the causes to which these successive transformations are due, it is more natural to evoke the most simple demonstrations, giving for reason the facts observed, and applying to molecular action the laws which govern mechanical phenomena.

After having essayed to explain the mechanism of electrolysis under the most general circumstances and in conformity with the explanation given of it in the diagram, it is advisable to enquire into the nature of molecular action which takes place under the two inverse conditions of polarity.

* A less considerable electromotive force than the minimum contra E.M.F. does not produce electrolysis; but, however slight it may be, it causes a current to traverse the electrolyte.

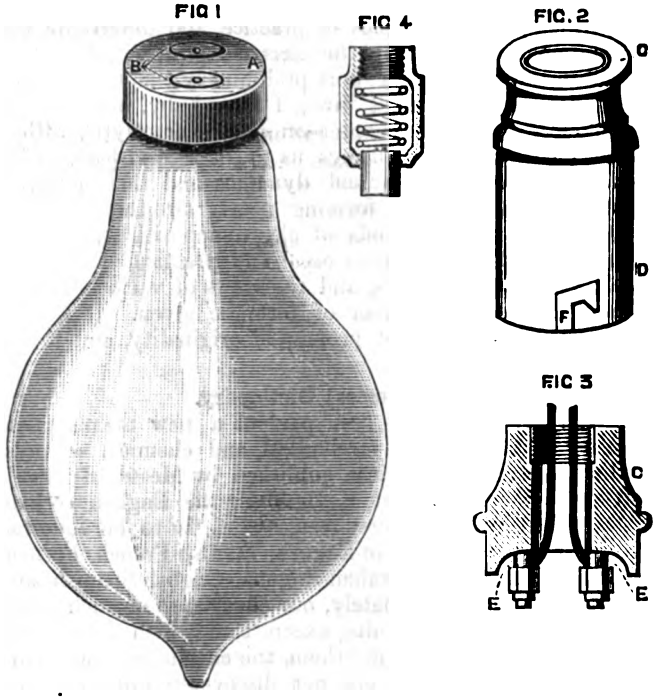
Professor Fleeming Jenkin says in his work, "Electricity and Magnetism," p. 68 (1st edition):—"Feeble currents also traverse electrolytes without producing any sensible amount of electrolysis."

Maxwell admits, in the case of electrolysis, two methods of transfer, one with decomposition and the other by conduction (see "Elementary Treatise on Electricity"). [Maxwell's words will be found on pp. 102—3 and 121 and 122, which we think hardly bear out Mr. Bandsept's views.—Ed. *E.*]

It is, in fact, more natural to suppose that the current should be partially employed in determining the state of dynamic tension which characterises the phenomenon of simple polarisation, and which enables the circuit to establish itself in consequence of the molecular continuity created by the double path of the SO's and the H's arranged as shown in the diagram; that is to say, the H's (cores) constituting the links of a central chain, and the SO's (flattened envelopes with polar apertures through which the contact of the H's is effected) composing the entire envelope, also continuous, of the entire core, from one electrode to the other—A B.

VITRITE LAMP HOLDERS.

Much ingenuity has been exercised in designing incandescent lamp holders, considerable advance having lately been made in electrical and mechanical improvements. Still, up to the present time there has been no great improvement upon the original forms, nor is there much diversity among them. One of the greatest troubles hitherto has been in regard to the platinum loops of the lamps; these being more or less fragile are apt, especially in the hands of the inexperienced or careless, to be strained or broken when the lamps are being attached to or detached from the holder. The "Vitrite" holder is a new invention, both with regard to material and design, and does away with this trouble, there being no strain at all on the platinum connections, while the lamp may be manipulated with great ease and safety by the most inexperienced person. Vitrite is a vitreous material, perfectly hard and incapable of fusion except at very high temperatures. It is also unaffected by damp, sea water, or even acids. In colour it is jet black, and it has a smooth, polished appearance. Its peculiar feature is that, while being a first class insulating material, it admits of the necessary mechanical connections for the conduction of the current being embedded in it in the



process of casting. This very much reduces the cost, and, besides lampholders, renders it suitable for cut-outs, switches, and other electrical appliances. In the accompanying woodcuts, Fig. 1 shows an incandescent lamp with the vitrite cap attached. The cap A, which is secured to the bulb by a specially-prepared cement, has embedded on the top two metal contact pieces, B, pierced with holes, through which pass the platinum wires connected with the carbon filament, and with which these wires make good electrical contact by means of a special amalgam. Fig. 2 gives an illustration of the holder, which consists of two main parts, the vitrite portion C, shown also in Fig 3, and the brass socket-piece D. In the portion C are embedded two split terminals, E, which receive the leading-in wires. Fig. 4 shows the combination nut and piston spring, which, being tightened down upon the wires within the split terminals, complete the circuit when the vitrite cap, in conjunction with the lamp, is pressed in the holder. The brass socket D is attached to C, so that it is easily removable. The slots F in the socket, by which the lamp is held, are adapted to serve, if so required, as a switch, twisting the lamp to right or to left, having the effect of turning it off or on. The holder generally is neat and finished in appearance, and is readily adapted to existing installations.

NOTICES OF BOOKS.

L'Electricite dans la Maison. Par E. Hospitalier, Paris. [G. Masson, 120, Boulevard Saint-Germain.]

This book is another popular exposition of the applications of electricity to the house. Lighting, telephony, electric-bells, electric clocks, electric cigar lighters, gas lighters, medical electrical apparatus, plating, games, locomotion—all are discussed; and it is shown how electricity is applied in each case. A book of this kind astonishes one, and brings forcibly into view the immense number of applications of electricity, and the increased number of applications of late years. Would it not be possible to introduce books of this sort into our schools, so that an interest might be given to what is frequently a dry task? Perhaps when it is fashionable to have French taught by Englishmen who know French, instead of by Frenchmen who neither know French nor English, common sense may have some power in deciding about school books, instead of pedantry. At any rate, such a book as this of Hospitalier's would form an easy and useful lesson book.

Electrolyse Renseignements pratique sur le nickelage, le cuivrage, la dorure, l'argentine l'affinage des mitaux et le traitement des minerais au moyeu de l'electricite. Par Hippolyte Fontaine. [Paris: Baudry et Cie, 15, Rue des Saints-Pères.]

The work is a very good compilation, intended for practical men, giving specific examples of practice, and describing the modern appliances used in the electro-deposition of metals. We find in the first place a short preliminary chapter on units and fundamental electrical laws, followed by one on the laws of electrolysis. A chapter on work electrolytic, with a number of useful tables, brings us to the second part, which describes various batteries and dynamos and their effective output. The third part, forming nearly two-thirds of the work, treats of various kinds of electro-depositions, such as nickel plating, gilding, and so on. The practice of English, French, and German houses, and the views of various authors are discussed, and a number of formulæ given. It will be seen that the book does not profess to originality, and it will be found good of its kind.

Technological Dictionary.

We have received the first part of a new technological dictionary of the physical, mechanical, and chemical sciences, including electro-technics, just published by Messrs. Symonds and Co., of Bouverie-street, E.C. This, the English-German part, compiled by F. J. Wershoven, D. Sc., is to be followed by seven others, viz., German-English, English-French, French-English, English-Italian, Italian-English, English-Spanish, and Spanish-English. Unfortunately, our experience of such works is that they contain everything except that which happens to be wanted; and, in reviewing them, the excellencies are manifest, while the deficiencies are not discovered until they are brought into practical use. We are, however, disposed to regard favourably this new work, which is calculated to be specially useful to electricians, as we find the words *polarimeter, polarisation, polariscope, to polarise, polariser, polarising angle,* and *polarity.* We also find *resistance, angle of, moment of, overcome, prejudicial, electric, battery,* and *external resistance;* and we hope that, in the next edition, *internal resistance* will also be added, as it is a term frequently in use by electrical engineers.

PROFESSOR TYNDALL ON THE SOURCES OF ELECTRICITY.

At his fourth lecture, delivered on the 3rd Jan., Professor Tyndall said he was anxious that every one might understand the growth of the subject of electricity. They would remember that he began by simple experiments on rubbed amber—the only knowledge of the subject given to man for 2,000 years. Then Dr. Gilbert broke ground by seeing that other substances besides amber possessed the power of attracting light bodies. So it went on, and ended with the electric machine, the action of which he showed in his last lecture. They would remember that Galvani's first observations were made in the year 1780. He was at a distance from the electric machine, and every time a spark was taken from the conductor the frog was agitated—a fact explained by reference to the return shock previously discovered by Lord Mahon. Six years after this an observation was first made in Galvani's laboratory. He hung his frog with a copper hook upon the iron railing of his laboratory, and finally found, when suspended, that his frog showed, in a very striking fashion, indications of electricity. Here was, in fact, an entirely new source of electricity. Galvani thought he had discovered the principle of light, and so did other men of his time. Volta said: "No, this is the old electricity, only developed from a new source;" and he came to the conclusion that it was developed by the contact of different metals. They must remember the difference between the first experiment of Galvani and the second. The first was explained on the principle that electricity was perfectly well-known; but the second pointed out to them a new source of electricity—voltaic electricity. He would now make an experiment which would illustrate where Volta's knowledge was wanting. A celebrated discussion was carried on between Volta and Galvani, and Volta worked at the subject for ten years, discovering his celebrated pile in 1800. In 1801 he went to Paris, and there showed his pile to General Bonaparte, who at once gave—or rather induced the Academy of Sciences to give—Volta a medal. In 1792 Volta wrote: "This is not anything else but electricity developed by the contact of different metals." And no doubt Volta was right to a certain extent. Placing a piece of copper and zinc together, the lecturer stated that the contact of the two caused positive electricity to flow over the zinc and negative electricity to flow over the copper. The contact of the two undoubtedly produced electricity. That was Volta's source of electricity, and Volta was right in part, but in great part wrong. Galvani, whom he overturned—and who, perhaps, fortunately for himself and his own peace of mind, died two years before the discovery of the pile—had, no doubt, some right on his side. There was such a thing as animal electricity. Volta was a more powerful man and a more powerful experimenter, and for a long time he entirely swept Galvani from the field. Mr. Cotterell had reminded him of a cell which he had there consisting of copper and zinc. He wanted, first of all, to throw a certain doubt on the explanation of Volta as to the contact of different metals by showing them an experiment. [Experiment.] When he dipped this cell into water they would see a glow of the platinum wire. They had the glow produced by simply dipping the cell into the water. Heat was a very powerful thing. Out of heat they could get work of all kinds, but it was impossible that work of all kinds and heat could be got out of contact between two metals. They could not get heat without the using up of some other form of force. They could not get mechanical work out of the mere contact of metals, as that would lead to perpetual motion. He would now show them where Volta's knowledge was at fault. They had before them in front of the lamp a little cell consisting of the combination he had just shown them, only simpler. There was there a little strip of platinum and a little strip of zinc, and they would see that wires were soldered one to the strip of zinc, the other to the strip of platinum. As long as these wires remained out of contact there was no action, as he showed them. Mr. Cotterell would now throw the image on the screen, and they would see what Volta did not see. When he brought the wires into contact they would see what occurred. They saw bubbles passing up the plate of platinum, but there were no bubbles whatever on the other plate. Volta was not aware of the chemical action going on within his cells, but they saw before them a specimen of that chemical action. The current that passed decomposed the water. The hydrogen was liberated on the platinum; the oxygen was liberated on the zinc. The zinc and the oxygen had a strong attraction. A combination of the two was produced and dissolved, and on the one plate they had bubbles, but not on the other. Volta knew nothing about this, not knowing the chemical action going on in his cells. That was the power within the cell which caused the production of heat outside the cell. It was the chemical action that caused the combustion of zinc in the cell; it was the combustion of the zinc in the cell which was the source and maintenance of the current outside the cell. He had there a cell of a substantially similar kind to that which they had already seen. It was devised by Sir William Grove. These forms of so-called voltaic cells were very numerous. They had there zinc and platinum, and as long as they did not bring them into contact there was no action. But the moment he caused contact [experiment] they had that little wire raised to a glow. While this development of heat was going on outside the cell, chemical action was going on in the cell. He might take the zinc and make a fire of it before them, but in the present case the zinc was burned in a liquid, and the difference between that burning and the ordinary burning was this—that in ordinary burning, if they put coal on a fire the heat was developed where the wood and coal were burned. But this form of combustion enabled them to transfer the combustion to a distance. He would now show them a battery of ten cells, and by that means they would get tenfold power, and they would be able to render a larger quantity, or greater length of wire,

Digitized by Google

incandescent. Instead of one small piece of wire from one cell they had a considerably larger amount. [Experiment.] The heat which they saw, if it were not developed in the wire, would be developed in the battery. It was transferred from there to the outside, and precisely in the same way they would be able to transfer chemical action. He would cause decomposition to occur outside the battery. [Experiment.] In the former case the cell was complete in itself, consisting of a plate of zinc and a plate of platinum, and they saw that that was capable of producing chemical action. They saw the water decomposed by the passage of the current. On one side they had one gas—hydrogen; on the other another gas—oxygen. Those two when combined were gases which constituted water. He next called their attention to an apparatus which he said was very well known in that institution, devised by Faraday. He also displayed a voltameter, and said it would enable him to show the decomposition of water on a large scale. He wished them to understand this experiment. There was a glass vessel containing acidulated water; there were two plates of platinum, and he would send a current from plate to plate. The passage of that current would tear the oxygen from the hydrogen, and on the one plate they would have oxygen liberated, and on the other they would have hydrogen liberated, and they would see the bubbles. The freed gases were mixed and a current sent into the mixture, when the gases combined with a loud noise. By a second experiment he caused a louder detonation; and by further experiment he obtained the pure gases on the surface of the soap suds. Taking up the bubbles in his hand the detonation was produced in a similar manner. By a further experiment, by means of apparatus which he said was devised by Mr. Cotterell for the purpose, he exhibited the two gases separated, in order to show that they were the two he had mentioned—oxygen and hydrogen. He tested the two by turning on a cock, and in the case of the hydrogen by placing a taper to the cock he produced a jet of light, which burned in the same manner as ordinary gas. The oxygen, on the other hand, he pointed out, would start a smouldering ember into a blaze. He would now pass on from this experiment, showing the heating power of ten cells to a higher heating power—that developed by fifty cells. Producing a platinum wire, he observed that he connected it with the battery of fifty cells. The end of the wire which he held was connected with a battery downstairs, the other end being connected with the platinum wire. [Experiment.] The incandescence followed the wire which he held, and finally it assumed a red heat. Breaking the circuit it went away, as he showed. He would now pass on to another subject, to illustrate a point of very great importance. He wished to show them, in connection with the first experiments, an experiment arranged there. Having called attention to a magnetic needle, and taking two plates—one of copper and one zinc—he explained that it was the mere contact of the two that caused the current of electricity. Instead of a frog, he (the lecturer) had a bit of beef, which he placed on copper, and Volta might have placed, and did place, his frog on copper in this particular way. He had a plate of platinum, which he placed on a plate of copper, and if electricity were developed they would know it by the action of the needle. [Experiment.] They observed the needle moving, and the electricity that now passed through the dead meat was the same as that which had passed to the frog. Volta, therefore, was not right in referring this source of electricity to contact of the metals. This experiment could be varied in many ways. Taking an apple he connected the wire coming from the magnetic needle, and inserting a fork into the apple, and cutting it with a knife, he explained that instead of acidulated water he had apple juice, which produced virtually a voltaic cell. He was now going to draw attention to an extremely important point—to a subject which he had read about a great many years ago, and which he had read about only that day. They had heard a great deal of late about what were called accumulators—that was stores of electricity. He had been looking at a journal and read a letter communicated to it regarding the secondary pile of Ritter. Ritter was a man of genius who was reduced to sufferings of all kinds, and he was sorry to say that he led rather an irregular life. He lived in Germany, and made experiments of an extraordinary kind, which were to all intents and purposes the experiments now made with the electric accumulator. He (the lecturer) had two plates of platinum held by means of a cork. He would first of all make a connection beween these plates of metal and the magnetic needle. There was no action whatever on the magnetic needle. The plates of metal being of the same kind were quite neutral. He would ask Mr. Cotterell to send a current from the battery outside through this cell. He would send a current through the water, which was acidulated water, and oxygen would be liberated on the one side and hydrogen on the other. They would have a film of oxygen on the one plate and on the other a film of hydrogen. Those two films would convert the platinum plates, which would act as if they were of different metals, and would produce effects on the magnetic needle. [Experiment]. He wished to show them the accumulator now used in practical life, and wished the boys before him to remember that it was out of seedlings and germs such as that of Volta that all our great practical applications grew, and they were produced by the discoveries of investigators who aimed at nothing but the love of science and nature. The nation or the community that severed itself from those discoverers, and that merely ran after the practical application of the germs, would soon find itself at the end of its tether. When he spoke thus he simply put in an appeal which was quite necessary. Every one understood that the electric light now seen in the streets was a great thing, but every one would not understand what a small thing it was from which it came. Of course when he spoke of the discoveries of Ritter, if they had not been developed they would not have been of use to humanity. He now wished to refer particularly to a gentleman whose battery he had shown at the institution twenty years ago—Planté. It was he who had made an accumulator on the principle of Ritter, but he used lead instead of platinum. He used lead, and produced a power not previously known. Others came after Planté and improved on his accumulator. He called attention to two cells of Sellon-Faure, and producing a thick platinum wire, he stated that it could not be heated to redness by the fifty cells, the power of which they had seen. [Experiment]. The thick piece of wire was made into a state of incandescence. It was (he said) a great thing to be able to produce such an effect with so small a battery and accumulator. These accumulators were now used for electric lighting, and they rendered the light perfectly steady. He had desired to connect this great result with that previously obtained by Ritter. To pass on to another region of the subject, he called attention to the discovery made in the year 1820 by Œrsted, of Copenhagen, who had been working at it for some time. [Experiment.] The lecturer placed a wire north and south. The magnetic needle was now under the wire, and they would allow an electric current to pass through the wire, and they would observe that the needle was deflected. This was the opening of a new region of discovery in regard to electricity—it was the opening of the region of electro-magnetism. He had an apparatus for reversing the thing he had called a current. He made a connection, and sent a current through the wire, and they would see how the needle was affected. [Experiment.] When he reversed it they would also see how the needle behaved. [Experiment.] He now wished to show them the result of using several coils of wire instead of one wire. He placed the needle between the coils of wire, and they would see that the action would be much more prompt, as the needle would be acted on by all the coils. [Experiment.] Clever men, seeing this action of the needle, said, "Is it not possible to make use of that as a signal—as a telegraph signal?" And from that discovery of Œrsted, Wheatstone and others discovered the needle telegraph. Only on the previous day he was thus enabled to send a couple of telegrams across the Channel by means of this needle. They would understand how it was possible, by arranging these deflections of the needle, to agree on certain signs, and how it was possible to invent a needle telegraph. This discovery of Œrsted was made in 1820, and it caused great commotion. Having next called attention to Arago's discovery, the lecturer stated that soon afterwards it was discovered that by putting a piece of iron within a coil of copper wire, by sending a current round about it, the iron became a perfect magnet. Producing a poker and a plate of nails, he showed that the poker had no action on the nails, but with the aid of a current [Experiment] they saw how the nails were attracted. By breaking the current they would see that the nails dropped. [Experiment.] He next exhibited an electro-magnet. This was a matter worked at by Faraday for twenty years.

PHILADELPHIA EXHIBITION.

THE CONTINENTAL UNDERGROUND CABLE COMPANY.

("*A. b.*" *of the Section's Classification.*)

This company's plans consist of two distinct systems. The first is described in Figs. 1, 2, 3, 4, and 5,* and the second is described in Figs. 6, 7, 8, and 9. While it is here described more particularly as an electric lighting system, it can as advantageously be applied to wires for other uses of electricity, and is adapted to cross streets, or where one company wishes its own separate conduit, the first-mentioned system being the trunk line system, to accommodate all the different companies in one plant.

In the trunk line system the conduits are constructed with a view of keeping the dampness from penetrating them by either making the walls of asphalte or asphalte blocks (or other anti-moisture material); or by constructing the walls of bricks laid with cement mortar, and covering the outside of the wall with asphalte or cement to keep the moisture out, and then keeping them constantly under pressure of dry air.

* We have not thought it necessary to show Figs. 1, 2, 3, 4, 6, 7, and 8, as all necessary details will be found in Figs. 5 and 9.

Digitized by Google

In order to use a comparatively cheap cable, the conduits are kept dry for the protection and preservation of the cables. And further, they are kept under pressure, and objectionable gases are kept excluded, as dampness or gases will not enter against inside pressure.

At first sight it may be said that there will be considerable cost attending the process of pumping dry air into the conduits; but a conduit of one, two, or three miles in length, may be kept under pressure by a very slight power from a single pump, which may be rented anywhere along the line and connection made to the conduits at a very small yearly cost to the company in conformity with the plan in the patent.

Every electric light company has an engine running to compress the air supplied at the generating station for the tubes containing their own wires, as shown in Fig. 6. The principal object in keeping the wires and conduits under dry air pressure is to prevent the escape of electricity from the wires, or reduce the escape to a minimum. While this principle is adapted to telegraph and telephone wires, it is particularly adapted to underground electric light wires, where very heavy currents are passed; for on long circuits the lights on the farthest end of the line or circuit burn dimly and are incapable of giving that brilliancy of illumination for which they are designed, unless the intensity of the electric current is greatly increased over the normal, and this is injurious to the lamps near dynamo electric machines, and requires a greatly-increased expenditure of power used in the generation of the current. By the use of the means employed by this company to retain the full force of the electric current, it is claimed that the distant lamps burn as briliantly as those near the generators, and all burn with a

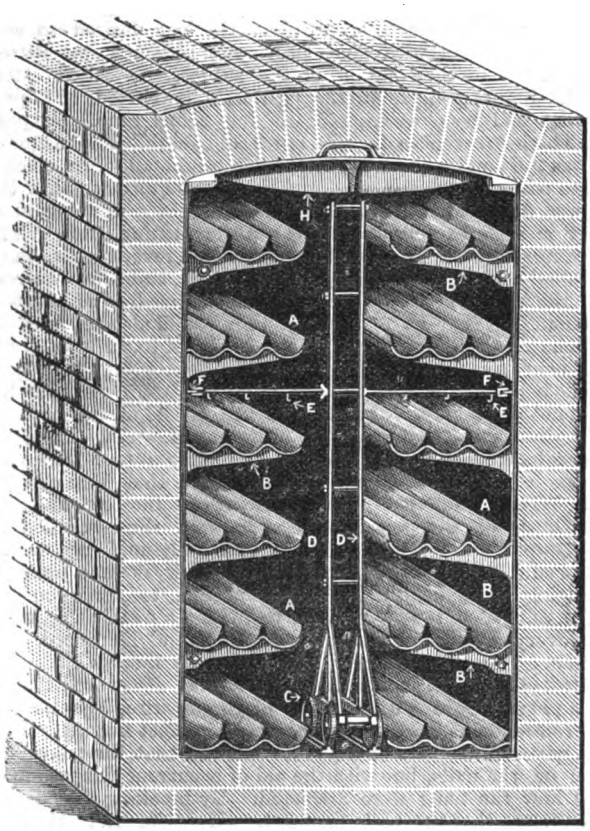

FIG. 5.—Inside measurement, 23 by 27 ins. Capacity, 7,200 wires.

maximum brilliancy without increasing the intensity of the current over the normal, and with a minimum expenditure of power. The accomplishment of this result depends mainly upon two phenomena, viz., the absorption of the moisture from within the conduits, by chemically dried air (the moisture rendering the air a good conductor), and increasing the pressure or density of the air around the conductors and within the conduit, by mechanical means, the same preventing the free escape of electricity from the wires.

The conduit should be made practically air-tight, with an air compressor at one end adapted to constantly force air into said conduit under pressure, and apparatus to contain an absorbent for the extraction of the moisture from said compressed air, and an escape or pressure valve adapted to remain closed until the desired pressure of air is obtained, and attached to the conduit at its other end or at different places along the conduit, and when the air compressor is put in motion to force a constant current of air under pressure into the main and out through said relief valves, and thereby insure a perfect circulation of chemically dry air under pressure.

The greater the pressure or more dense the atmosphere, and the more free the air is from moisture, the less liability is there for the escape of electricity; and, *vice versâ*, to follow a natural law which has been demonstrated, the more rarefied the air around an electric wire and the more moisture it contains, the more freely will electricity escape from the wire. By this process every part of the space within the conduit (not occupied by the wires or their covering) will be occupied by compressed or dense dry air. The insulation should be perfect, as there will be no space so small that the compressed air will not instantly penetrate it. In the case of electric light wires, they will be supported within a tube by glass or porcelain supports, as represented in Figs. 7 and 8, and each wire having an air space surrounding it, the dry compressed air will encircle each wire and insulate it perfectly from all others. A slight insulating covering as an extra precaution should be used on the electric light wires also.

One of the simplest forms, system No. 1, is shown in Fig. 1. A conduit for one or more cables of wires is arranged on either side of the track to accommodate, combined, 800 wires.

That shown in Fig. 1 will probably be sufficient for any one company for many years to come, but where more wires are required the capacity of Fig. 2 should be had, and any single company will probably never require on any street more accommodation for wires than can be had by the conduit shown in Fig. 1; but should a greater capacity be required, the construction shown in Fig. 2 may be used, in which it is seen that pockets are arranged in a manner similar to that shown in Fig. 1, but two deep. In place of arranging pockets as shown in Fig. 2, they may be arranged as shown in Fig. 3, in which the pockets are arranged in single rows, one above the other, four deep.

Figs. 4 and 5 show the system for laying wires on a larger scale, and which is especially adapted to accommodate a number of separate companies. Each of said figures shows the same capacity with but a slight difference in construction, the arms supporting the pockets in Fig. 4 uniting both uprights, and a track is furnished to each apartment of six pockets; while in Fig. 5 the arms or brackets do not thus unite, but leave a vertical passage way from top to bottom of the conduit wherein the motor or carriage, running upon the rail of the bottom, causes its adjustable arms to travel when in the act of laying the cords, wires, or cables in the various pockets upon either side of said passage way. For an entire city only one motor and one carriage will be required, or if the process of laying the wires is to be carried on by either the carriage or motor alone, then the one or the other may be dispensed with; the pockets are made semi-cylindrical, three inches wide at the top and an inch and a half deep, or they may be made nearly cylindrical with a slot on the upper or top side running the whole length to admit

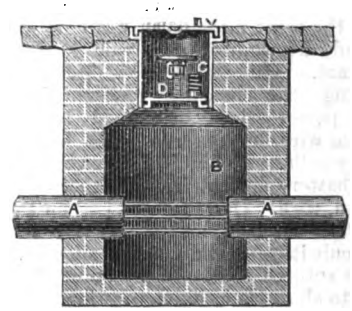

FIG. 9.—Airtight manhole.

of the chain or cord being laid in the pocket by the car with which to draw the cables into position. The space for the motor is between five and six inches wide, but reduced to two inches above the railway, and as it extends from the bottom to the top of the conduit, access to the cables without removing them from their pockets can be had from the top if at any time it should be desired or become necessary.

A vertical space of one to two inches is left between the upper and lower pockets, to enable the passage of the motor or carriage arm and also to enable the cable to be tapped and the wire taken through an outlet.

Service from the conduit to houses may be made by a connection run under the sidewalk and into the cellar, as shown in Fig. 3, conveying wires through said pipe into the houses. The conduit before each house is provided with a plugged branch, which may be opened for connection when required.

Where a number of companies are using the construction shown in Fig. 4, each of said companies can place a suitably arranged lock against admittance to their respective apartments.

Fig. 3 shows an electric motor in the act of drawing a cord or wire cable from a spool supported by an adjustable upright, temporarily placed in a manhole for the purpose, this cable when laid, being adapted to draw the carriage through, which in turn lays a series of cords or cables in the various pockets, as shown in Fig. 2. If it is required that the carriage make two or more trips successively, then the carriage, in being drawn through, may also draw through an additional cable (see Fig. 2), by which said carriage may be returned after laying the first lot of cords or electric cable, and be in readiness for a second supply.

The plan is to place the largest number of wires in the smallest possible space after allowing for space to conveniently get at the wires, lay and relay them, for taking them off to houses and for circulation of dry air, &c.

The walls of the conduit may be built of blocks made from asphalte compound, by an improved process, whereby it becomes impervious to moisture, and possesses great strength; and the metal uprights, brackets, and pockets are connected with the earth to carry off induced electric currents to the earth. By this construction the conduit can be built more cheaply than if constructed entirely of iron, and in addition thereto is not so apt to become electrically charged.

The cylindrical sheet-iron pockets are formed by machinery, and in sections of four to six feet long, the ends of which are turned to receive the supporting brackets, which clamp said pockets from end to end. The uprights and brackets are bolted together in a manner as to clamp firmly the ends of the pockets, thus uniting the adjacent sections, and thereby

Digitized by Google

securing a substantially smooth pocket or trough extending from one manhole to the next, the smooth surface overcoming any danger of injuring the cables in the act of drawing them through, and at the same time decreasing the labour. The uprights and pockets with the railway are fitted in the machine shop, and several sections, secured together, are lowered simultaneously to the foundation made for it in the street. These are then closed in, and the conduit is complete.

It is estimated that the system just described can be laid with a capacity of 12 to 15 pockets adapted for different companies to occupy separate pockets for their own wires, each pocket having a capacity of 100 to 200 wires (according to the kind of wires or cables used), for from 8,000 dollars to 10,000 dollars per mile, depending upon the material used in the masonry.

Fig. 6 represents a general view of our electric lighting system, in which we have to deal with currents of electricity of high electromotive force. In such systems in moist weather, or even owing to the dampness of an underground conduit, there is an escape of the current, and this materially reduces its tension so as to render the current incapable of producing a light of more than small candle-power at a short distance from the generating station. This has been one of the obstacles to placing electric lighting wires under ground where the current was to be conveyed over long distances.

By this system the tension of the current is retained at its maximum, and so far as dampness is concerned the tension is unaffected, thereby conveying currents underground over even longer distances than can be done above ground, under the ordinary variations of the hygrometric state of the atmosphere.

To attain this end the air within the conduit is kept under considerable pressure, and perfectly dry. If there is any appreciable amount of moisture in the atmosphere, the air-pump H forces the air first through a dryer, G, which absorbs all the moisture, and the chemically dried air passes into the conduit A, and when the pressure becomes over a fixed amount, the relief valves C allow the excess of air to pass off, thus keeping the pressure in the conduit uniform. Currents of high tension tend to pass off the conductors, but this tendency decreases as the pressure of the surrounding medium (air) increases, and this effect is greatly increased by the thorough drying of the air in damp weather before passage into the conduit. The drying chemicals may be used over and over again, and the system is adapted to any substantially air-tight conduit. As the pressure is constant there must be an efflux, and should there be a small leak the passage of air will be from inside outward, thus preventing ingress of moist air.

Figs. 7 and 8 represent end sections of conduits for electric lighting purposes, in which B are the conductors and A a metal pipe, the conductors B being supported by suitable insulators within said pipe. The conduit A (Fig. 6) may be continuous, with testing doors in the manholes B, or if desired the conduit A may be open on the ends where it enters the manhole, as shown in Fig. 9, in which the door D is made air-tight and covered by an auxiliary cover, F, on the road, the said door D being provided with the relief valve C. In this construction the manhole is filled with compressed air.

This principle may be applied to general conduits, which may also carry the electric light wires, or instead of supplying the whole conduit with compressed air the electric light wires may be enclosed in leaden or iron tubes, and when laid in the conduit, air may be forced under pressure through said pipes.

Comments by the Examiners.

While the system just described is more particularly intended for electric light wires, if applied successfully to currents of high tension it can more easily maintain a good electrical condition for telegraph and telephone wires; and a pipe conduit 3½in. in diameter can be laid for about 3,000dols. per mile, and will contain at least 300 wires.

If absolutely dry air could be maintained in this conduit no doubt it would be attended with many of the advantages claimed for it. But it would be exceedingly difficult to ensure in any conduit of masonry, however carefully built, absolute immunity from moisture, and to keep such a conduit with as many manholes and outlets under air pressure, would, it is thought, be quite impracticable.

The employment of an electric motor to run a cord or chain through the duct for the purpose of feeding in the wires appears to be a refinement which, to say the least of it, lacks simplicity. Further, the expense of maintaining dry air under pressure by a separate apparatus would be an expensive process both in first outlay and subsequent maintenance.

The employment of dry air, however, in wrought-iron pipes has obvious merits as a cheap and manageable insulator, and is well worthy of being developed. The details of the system have not yet been worked out, and the models exhibited showed a new principle, but not so far a practical system.

THE COSMOPOLITAN UNDERGROUND TELEGRAPH, TELEPHONE, AND ELECTRIC LIGHT COMPANY OF NEW JERSEY.

Patented May 8th, 1883.

(*"A. b." of the Section's Classification.*)

This conduit is constructed of highly glazed terra cotta, in sections 2ft. in length, with a tap joint on the top and ends, and is bedded on a cast-iron or terra cotta base plate.

Its interior is fitted with iron frames, placed at suitable distances apart, which clamp large plates of some suitable insulating material, such as glass. If bare wires be used, they may be drawn directly through the holes, but where insulated wires are employed, the opening should be fitted with short sleeves of porcelain or glass, to prevent the insulation being injured.

Some of the sections are fitted with tubular projections for tapping the wires, wherever required, for house-to-house supply.

Cast-iron manholes are placed at suitable intervals.

The slack of the wires is taken up every fifteen feet, and the wires are then clamped.

All the joints are carefully cemented in order to exclude moisture.

It is stated that about one hundred yards of this system has been under trial in Fourth-street, Camden, N. J., and that the cost will not exceed one dollar per foot run.

No provision is made for overcoming the effects of induction in telephone wires. After the duct has been laid and filled with wires, no addition or alteration to the wires can be made without laying open the street down to the level of the base of the conduit and re-making all the joints.

(TO BE CONTINUED.)

THE DRAWBAUGH TELEPHONE CASE.

AMERICAN BELL TELEPHONE COMPANY AGAINST THE PEOPLE'S TELEPHONE COMPANY ET AL.

(CONTINUED FROM PAGE 317.)

As has been remarked, Drawbaugh seems to have discovered nothing accidentally, yet from the beginning to the end of his narrative there is nothing to indicate the conceptive origin or the mental growth of the alleged invention. He presents a number of devices in the chronological order of their production, and testifies that he made one and then another and another, as experiments led him to modifications and improvements. He cannot describe what receiver or other apparatus he used with his first transmitter, and testifies: "I had a number of crude apparatuses, but can't remember exactly the shape of any of them. I had membranes stretched over hoops—over a hoop I remember that; and I had electro-magnets, and the arrangement was varied; I don't remember exactly the arrangement." He testifies that when he used the cup machine he used it in a continuous electric circuit, and thinks he used it as a receiver with Exhibit B as a transmitter. He states that he succeeded in transmitting speech with these two instruments, and, of course, he could only have done this by employing the unbroken undulatory current of electricity. He cannot state how he conceived the initial ideas of the undulatory current and the continuous circuit, or subsequently the theory of any of the remarkable devices which he produces. His answers to questions intended to elicit such information may be illustrated by giving one of them:—"I don't remember how I came to it; I had been experimenting in that direction; I don't remember of getting at it by accident either; I don't remember of any one telling me of it; I don't suppose any one told me." He produces sketches or models or originals of instruments which he says he made from time to time; he states that they were used to talk through on various occasions; and from these outlines of accomplished facts leaves the history of his inventions to be filled out by inference and conjecture. An inventor can hardly forget the process of thought by which a great intellectual conception germinates and matures into the consummate achievement; but Drawbaugh's memory is a blank. If the untutored mechanic educated himself into an accomplished electrician by his own experiments and observations, the incidents and phenomena which revealed new discoveries and illumined the way for new advances would be indelibly impressed upon his mind.

Another group of important facts which are satisfactorily shown by the proofs are those which indicate Drawbaugh's own knowledge that he was not an original inventor of the telephone. Reference has been made to some of the evidence bearing upon his neglect to patent or caveat his invention in discussing the question of his credibility as a witness.

If no honest and reasonable explanation can be given for his conduct, the inference is very strong that he knew he did not have a practical telephone to patent. He may have had a talking machine which was well calculated to excite the curiosity of the community in which he lived; he may have indulged in expectations that in time he could succeed in making a practical speaking telephone, and reap fame and profit from it, but his conduct is almost decisive against the supposition that he had even deluded himself with the belief that he had produced anything sufficiently practical and valuable to patent. He never attempted to exhibit it outside of his own shop to prove that it would transmit speech at a distance of even a quarter of a mile. The proofs show that during all the years from 1867 to 1873 he did not attempt to avail himself of opportunities for demonstrating his invention and bringing it to the notice of friends who were peculiarly qualified to appreciate, and were favourably circumstanced to assist him. One of these persons was Mr. Kiefer, who resided at Harrisburg from 1863 to 1881, and during that period had charge of the telegraphs of the Pennsylvania Railroad Company, and was a member of a firm whose business was the manufacturing of fine electrical machinery. In 1873 he put up a fire alarm system for that city. Drawbaugh made his acquaintance in 1874 or 1875 and brought his magneto fire alarm to Mr. Kiefer for examination. At another time he brought the works of his electric clock. He visited Mr. Kiefer on various occasions, obtained small supplies from him, and habitually conversed with him upon the subject of his electrical contrivances. The period of these visits begins just about the time when according to the theory of the defendants Drawbaugh had constructed Exhibits E and D and the invention was complete. He never mentioned to Mr. Kiefer the fact that he had experimented with a telephone. Mr. Wilson was superintendent of telegraphs for the Northern Central Railway Company at Harrisburg from 1864 to 1875. He was also Mayor of Harrisburg.

Digitized by Google

The company had an electrical workshop and supply establishment there for Mr. Wilson's department between 1871 and 1875. During this time Drawbaugh often came to the supply shop and talked with Mr. Wilson about electrical experiments, and obtained parts of batteries, coils, magnets, and other electrical material which the company had cast aside. He brought Mr. Wilson his electric clock and his magneto-electric key, and tried his machine for short line telegraphing at Mr. Wilson's office ; he talked with him frequently about his inventions, but he never mentioned the telephone. His relations with David A. Houck were such that the latter procured him an opportunity to test his magneto key at the telegraph office of the railroad company at Mechanicsburg. Mr. Stees was superintendent of a car company at Harrisburg, having shops in different parts of the city connected by telegraph lines. He was the first person to employ Bell's telephones on these lines when they were introduced into Harrisburg late in 1877 or early in 1878. He was a friend of Drawbaugh, and Drawbaugh would naturally have applied to him if he wanted to test his telephone publicly or practically. Isaac Lloyd was a school teacher and an alderman at Harrisburg ; had known Drawbaugh long ; was accustomed to visit his shop from time to time ; saw many of Drawbaugh's inventions ; was present on one occasion when Drawbaugh experimented with his magneto device for telegraphing at Mr. Wilson's telegraph office. Drawbaugh visited him frequently, and they were accustomed to converse about Drawbaugh's inventions. Drawbaugh showed him his dial telegraph, his electric fire alarm apparatus, and numerous other inventions. Witness assisted him about the electric clock. He was an owner of patents and a friend to whom Drawbaugh applied for loans, and was interested in mechanical subjects generally. The only mention ever made to him by Drawbaugh about a telephone was in 1878, when Drawbaugh told him he was experimenting with a telephone. From 1867 to July 1873 Drawbaugh was intimately connected with the persons composing the Drawbaugh Manufacturing Company, which was engaged in manufacturing devices under Drawbaugh's patents. He was a stockholder and the master mechanic of this company. Among the officers and stockholders were many men of capital and enterprise. There came a time when the managers of the company wanted Drawbaugh to suggest new devices for the company to manufacture. He never suggested the telephone nor attempted to induce the managers of that company to investigate or exhibit his talking machine. A number of the managers and *employés* of this concern testify that they never heard of the existence of the talking machine during the life of the company. Without attempting to refer to other testimony to the same general effect, what has already been referred to shows that if Drawbaugh had seriously desired to bring his talking machine into public notice, and secure the fruits of his invention, he had ample opportunity to do so. Who can doubt that if he had a practical telephone to exhibit, he would have selected just such men as Kiefer, Wilson, and the others to demonstrate it to them and enlist them to demonstrate its utility and value to the public ?

Such an invention was of a kind well calculated to excite public interest, and to impress practical men with a quick appreciation of its commercial importance and its pecuniary value. It was sufficiently perfected, according to the theory of the defence, that a patent could have been obtained prior to 1870 to secure the application of the principle, and to compel every subsequent inventor to pay tribute to the discoverer of a new art. For years it was mechanically perfect, and its efficiency and importance as a great factor in human intercourse could have been demonstrated to the public without appreciable inconvenience or expense. Drawbaugh fully appreciated its importance and value. He had the means to patent it himself, and friends to assist in introducing it into public use. He had the talent to induce others to invest in his inventions. No explanation is possibly why, under such circumstances, his efforts should have left no mark upon the annals of inventive progress, and given no evidence of life beyond the idle curiosity his talking machine excited in the circle of his admirers during all these years. His conduct is more persuasive to show that he did not have a practical, operative telephone than the testimony of a multitude of witnesses who may have seen and heard talking machines at his shop during this period. But the complainant has given evidence of his declarations made by him before he had any interest to pervert the truth which afford a reasonable explanation of his conduct, and go far to explain how the testimony of the corroborative witnesses may be reconciled with the truth.

In 1874-6 Drawbaugh issued a business card advertising himself as "Inventor, designer, and solicitor of patents." On the back of this card is printed a list of his inventions as follows :—Stave heading and shingle cutter, barrel machinery, stave jointing machine ; tram and red-staff for leveling face of mill-stones ; rine and driver for running mill stones ; nail machinery for feeding nail plates ; pumps, rotary and others ; hydraulic ram, the Drawbaugh rotary measuring faucet ; carpet rag looper, electric clock and magneto-electric machine for short line telegraphing and fire alarm and propelling electric clocks. He takes pains to say of this magneto machine on his card that it can be applied to any form of electric movement, and dispenses with a galvanic battery. He had obtained patents for some of these inventions, but he had not for others. He was then experimenting with his electric clock and with his magneto machine for short line telegraphing, fire alarms, &c., and including them in the list of his inventions. The omission to mention the most important one of all of his inventions, one respecting which, according to his present testimony, there had not been a week from the time he made his first cup machines that he had not been engaged with it, one which was complete before his electric clock was complete, is a significant statement by implication that he had no such invention to advertise.

It is to be remembered that when he chronicled his achievements in the autobiographical sketch of 1878, the Bell telephone had been introduced into commercial use at Harrisburg, three miles from Drawbaugh's shop, and the local newspapers had been full of the subject. The cursory allusion in that autobiography to "several kinds of telephones" is in striking contrast with the elaborate description of the electric clock, and wholly inconsistent with the theory that he deemed himself to be the originator of the invention which at that particular time was a topic of universal interest.

In his testimony given in 1879 in the interference proceeding with Hauck, although he did not include the talking machine in the category of his successful inventions, in the course of his testimony he produced a sketch of his faucet, and stated that he made it "about 1874 to 1876 when I was experimenting on telephones or phonographs." He represented himself not as an inventor of that which he is now claimed to have perfected, but as an experimenter with a "telephone or phonograph." It is instructive to read this statement in juxtaposition with a statement made by him to Mr. Matthews in the preceding year. Mr. Matthews was the managing editor of the *Baltimore American*, and in April, 1878, made a visit to Drawbaugh at his shop to see Drawbaugh's magnetic clock, in consequence of information received from a correspondent. He was a careful observer, who went there obviously for the purpose of writing an article for his paper. That his memory is unusually retentive and accurate, and that he is a careful and conscientious man is apparent from a letter written by him in December, 1883, after the proofs in the case had been closed, and in which he manifests a desire to correct certain errors of detail in his deposition. Upon that visit his attention was chiefly directed to the clock ; but he examined Drawbaugh's other inventions, and conversed with him about them, and, among other things, conversed about the telephone. Drawbaugh's statement to him on that occasion was that he had invented apparatus to send messages by means of an alphabet founded upon difference of sounds. He did not profess to be the inventor of the speaking telephone, or assert that he had ever transmitted speech successfully with his apparatus. He said that the idea of transmitting sounds in this manner was not new, and he had read of it some years before in a publication translated from the French, and denied Bell's right to claim the invention of the telephone, because of that publication. In the article founded on that interview which Mr. Matthews subsequently wrote for publication in the *Baltimore American* he adverts to the several useful agricultural and mechanical devices patented by Drawbaugh, and adds : "It may be mentioned that Mr. Drawbaugh constructed a rude telephone long before Mr. Edison loomed up as the 'boss' inventor. He never expected to send articulate sounds over a magnetised wire, but he believed that an alphabet could be arranged after the manner of the musical scale, and that messages could be transmitted and understood by the variations of tone and pitch. This unlettered mechanic came very near anticipating Edison and Bell in the invention of the telephone, and nothing but his poverty prevented him from conducting his experiments to a successful issue."

His advertising card, his testimony before the Patent Office, his autobiography, and his statement to Matthews authenticated in writing were all made when he no had pecuniary interest to colour the facts, and upon occasions when he was anxious to present himself in the most favourable light as an inventor ; and they were all made after his talking machine, according to the theory of the defendants, was a perfected invention, and known to be such by many of his friends and neighbours.

These are declarations, evidenced in writing, and one of them made under oath, which point in but one direction. They are consistent with his conduct. They show that he understood himself to be an experimenter with telephones or phonographs, but not the inventor of the speaking telephones.

The complainant has supplemented this evidence by the testimony of other substantial witnesses who had favourable opportunities to know what Drawbaugh had invented, and who describe what they saw and did not see at his shop, and narrate what he said about his talking machine on various occasions. This testimony indicates that at as late a period as in 1878-79 Drawbaugh was an experimenter, but not the author of the parent invention, nor one who had perfected any valuable improvement upon it, and is in substantial accord with his statement to Mr. Matthews and his testimony in the interference proceedings. What gives point and force to this testimony, and carries the ordinary objections to the reliability of verbal declarations is, that these witnesses are persons who would have been forcibly impressed because of their interest in the particular subject by any assertion by Drawbaugh that he was an inventor of the telephone. During the time in question Drawbaugh had friendly relations with the newspapers of the vicinity ; his friends were frequently communicating laudatory notices of his mechanical and inventive efforts to the press, and he himself visited one of the newspaper offices in the spring of 1878 to show a telephone he had made. The newspapers had published articles about the Bell telephone, but up to the spring of 1878, while many notices had been published in them about his electric clock and other inventions, describing him as a man of extraordinary genius, there had been no mention of the telephone ; and when, in the spring of 1878, the subject was mentioned, he was referred to as one who was "inventing a telephone on a different plan from that now occupying the attention of the scientists," and as about completing the new telephone he is now constructing.

In this connection it is to be noted that, soon after telephones were introduced in Harrisburg late in 1877 or early in 1878, Drawbaugh visited the offices where they were used, examined the inside of the instruments, and borrowed one to take home, which he kept for several days ; and the instrument which he borrowed bears a close resemblance in appearance to Exhibit A, which, it is asserted, he had made in 1873 or 1874.

No extended reference will be made to the testimony of other witnesses such as Mr. Weaver and Mr. Grissinger, showing declarations of Drawbaugh made after the Bell telephone was in commercial use, to the effect that, although he had experimented on the telephone years before Bell, he had obtained no satisfactory results.

(TO BE CONCLUDED.)

COMPANIES' MEETINGS & REPORTS.

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The twenty-first ordinary general meeting of this Company was held at the Cannon-street Hotel, on the 24th inst., under the presidency of Mr. George Henderson.

The SECRETARY (Mr. William J. Tyler) read the motion convening the meeting, and the report of the Directors was taken as read. It has already appeared in *The Electrician*.

The CHAIRMAN: Gentlemen, considering the many complaints one hears on all sides of reduced business and shrinking profits, I think we may be well satisfied with the statement of accounts we are rendering for last year and be thankful for it. The dividend we are recommending is a good one, and if to some of the shareholders it seems that we might do more in that way, they may rest assured that the matter has been well considered by the Board, and that we have good use for the undivided profits we are putting to reserve and carrying forward. In fact, we have felt the need of more capital for some time, and the decision to issue new shares in the terms of the allotment letters now in your hands not only provides more capital, but gives the shareholders a substantial bonus at the same time. More capital, I need hardly remind you, means less borrowing, and therefore less interest to pay, and an important saving by way of discount on all purchases. I need add nothing to the satisfactory statement in the report as to the increased sales of last year. We shall push our business in all directions vigorously, but I hope prudently, both in the old grooves and the new ones opened to us by our Act of Parliament. The fresh capital you are supplying will much facilitate our operations, and I expect will yield you a good return on your investment. We have had several small cable contracts during last year. The Senegal cable was laid towards its close. The 6 per cent. debentures of the Spanish National Submarine Telegraph Company, which we took in part payment for our cables, and which figure in the item of £130,737 in our balance-sheet, seem to us to be a good investment. At a favourable opportunity we intend to issue them. I may explain that the Cape de Verde cable mentioned in the accounts is a short line, between St. Vincent and Santiago, laid under engagements with the Portuguese Government, with the view of connecting those islands and Western Africa—a work which we shall hope to have more to say about on a future occasion. With reference to the premium on the new shares I may mention that we shall add this to the reserve fund. Should the shareholders require any explanation respecting the allotment letters, I shall be glad to give it. I shall now propose:—"That the report and accounts now presented be received and adopted, and that a dividend of £1 per share, tax free, payable on and after the 25th inst., be now declared." When that has been seconded I shall be glad to hear any observations which the shareholders may desire to make.

Mr. S. W. SILVER: I have very great pleasure in seconding the Chairman's motion.

Mr. DIXEY said he noticed that that was the 21st ordinary general meeting of the Company, so that they might regard it as having attained its majority that day. He thought the Directors were entitled to the hearty congratulations of the shareholders, for the Company, under their able management, had reached a position of which they might well be proud, especially as the success of the past promised to be still greater in the future. The Directors had marked this coming of age of the Company by a proposed addition of £104,000 to the capital, and if the Company had justified the shareholders' expectations in the past with a capital of £312,000, yielding as it had this year 15 per cent., he ventured to predict that with a capital of £416,000 it would in all probability exceed their expectations in the future, and give them a dividend of 20 per cent. Larger means implied larger possibilities—the creation of new business, expansion, wider development, and under the present Directors he was sure that that meant increased net profits and increased dividends. They had heard from the remarks of the Chairman that the past year had been one of unparalleled depression, and the Directors of many public companies had had to meet their shareholders almost with a feeling of shame and trepidation. They had had very sorry balance-sheets to present, and no dividend to declare. That was not the case with the Directors of their Company. They met the shareholders that day with a good balance-sheet, and with the intention of declaring a dividend of 15 per cent., and the shareholders also heard words of good cheer for the future. The addition of £104,000 to the capital of the Company had been made altogether irrespective of that meeting consequent on powers conceded to the Directors many years since; but he felt sure it would be satisfactory to the Directors to know that their course of action was thoroughly endorsed by the shareholders, and that while the latter gratefully appreciated the services of the Board in the past, they cherished the greatest confidence in their good management as to the future. He was not going to propose a formal vote of thanks, as that would no doubt devolve on some one else more competent for the duty than himself; but as an old shareholder he was sure that the prosperity of the Company was owing to the management, and he felt that he could not say less in acknowledgment of what had been done for them.

Mr. LAMONT said he would like to ask a question about the increase of capital. No doubt the accounts which the Directors had put before the shareholders were of the most satisfactory character, especially in comparison with those which other companies had been able to submit to their shareholders; but it hardly appeared to him that the Directors were pursuing the most economical course with regard to the raising of fresh capital. An addition of £100,000 to the capital, if they took the dividend at the same rate as the present one, signified a charge of £15,000 a year on the Company in some form or other. They had an amount of £100,000 mortgage debentures, and he could hardly see why they should not proceed further in that direction. He thought that would be a very great saving to the Company. They were going to have, as proposed, £100,000 at an expense of £15,000 a year, but if they were to raise mortgage debentures, even on the same terms as before—and, he presumed, with the improved credit of the Company, those debentures could be raised at 5 per cent. instead of 6 per cent., but assuming that they gave even 6 per cent.—there would be a saving of £6,000 a year. They would tell him probably that they had £50,000 in hand, but that was, so to speak, a gift made to them. But seven or eight years would clear that off, and therefore it appeared to him that it would be a preferable course to raise money by mortgage debentures than by issuing fresh capital. There was, he thought, another consideration with regard to this matter. They might not always find their trade so good as it had been. There might be changes, and they might not always want so large a capital. It might prove a burden at some future time. Increased competition, which they found growing fiercer every day, might lead others to drop some manufactures, or they might not want so much capital as they now thought they required. In that case they would be in a difficulty. They would have the increased capital, and would want to keep up the dividend; or, if they had to return any part of the capital to the shareholders, they would have a difficult task to perform in the return of the money, and they would have to add the word "Reduced" after the title of the Company. Were the Directors thoroughly well satisfied that the course they proposed was the best? It did not appear to be so to him. He thought they would save money by his plan, and that it would be better to have the opportunity of paying off debentures as they fell due; whereas, by the course proposed by the Directors, they would have a weight of capital on their shoulders upon which they might not always be able to pay so good a dividend as they were now proposing.

A SHAREHOLDER asked whether the £130,737 referred to by the Chairman was all in debenture stock or in debenture stock and shares.

Mr. KELSO desired some information with regard to the purposes of the reserve fund. Was it for equalising the dividends? He thought the shareholders would also be glad to receive some assurance as to the limit it was to reach.

Mr. SMALL wished for an explanation of the difference of £50,000 between this year and last in the item of stock-in-trade.

Mr. COCHRANE said he was aware that by the Articles of Association a certain fixed percentage of depreciation was arranged for this Company, but he noticed that they had about £446,000 as representing the property of the Company, whereas the depreciation was only £14,000—apparently only about 3 per cent. That appeared to him to be inadequate.

The CHAIRMAN: In answer to Mr. Lamont's query about the new capital being raised economically, there was a distinct understanding at the time the mortgage bonds were issued that no more of them should be issued while those existing were running. We think that this is the best way of raising the capital we require, and the cheapest way for ourselves. We have had to borrow money, and to pay interest for it, as it is required; but we shall save that, and I think that the new capital will save us a good deal of money. As to the £130,737, the accounts state distinctly that that amount is partly in shares and partly in debentures. It is mostly debentures.

A SHAREHOLDER said it was the market value that he desired to be assured of.

The CHAIRMAN: We think we have kept them well within the market value. We have not put them on the market yet, but we think they are well worth what they stand at in our books. Mr. Kelso has asked the object of our reserve fund. We use it in our general business.

Mr. KELSO asked whether it could be employed for equalising the dividends.

The CHAIRMAN: If we come to require it for the purpose, we think it can be so used. Article 94 of the Articles of Association says: "The Directors may, before recommending any dividend or bonus, set aside out of the profits of the Company, or out of such moneys as aforesaid, such sum as they may think proper as a reserved fund to meet contingencies or for equalising dividend, or for extending, repairing, or maintaining any of the works connected with the business of the Company, or any part thereof; and the Directors may invest the sum so set apart as a reserved fund, subject to the provisions as to the investment of the funds of the Company herein contained." We have hitherto required it entirely for our business.

Mr. KELSO said he had not questioned the authority of the Directors.

The CHAIRMAN: No; we can use it for anything.

Mr. SMALL put a question as to the difference in the stock between 1883 and 1884. It was the Senegal cable principally that caused the difference. As to the depreciation, that is settled by the Articles of Association; but, of course, we have in the £446,000 our steamships. They are standing at a very low value in our books, therefore, and we have not reduced them at all this year. I think I have answered all the questions.

Mr. KELSO did not think the question as to the reserve fund had been sufficiently replied to. How far was it to go on increasing? They had added £20,000 to it this year. If the Directors informed them at what point the reserve fund was going to stop the shareholders could form some view, perhaps, of the position.

The CHAIRMAN: We have not considered that at all yet. The exigencies of the business must guide us to a certain extent.

Mr. KELSO thought a sum ought to be fixed—£300,000, or whatever it might be—and then the shareholders would know what they were doing.

The CHAIRMAN: Well, I am not in a position to answer that question.

Mr. LAMONT agreed that if the Directors were under a pledge not to issue any more mortgage debentures the suggestion he had made would fall to the ground; but he could hardly admit that it was a saving of

Digitized by Google

money to raise capital by the issue of shares. They could not be paying more than 5 or 6 per cent. for borrowed money, and the Company, in raising capital by shares, would lose the difference between that rate of interest and 15 per cent., the present rate of dividend.

The CHAIRMAN: We think you will find that we can make good use of that money, and turn it to good profit.

Mr. LAMONT asked whether the Chairman could indicate the various kinds of manufactures they intended going into.

The CHAIRMAN: I would rather not, if you please [laughter]. He then put the motion, which was carried unanimously.

Mr. SILVER then moved the re-election of Mr. Abraham Scott as a Director of the Company, and testified to the value of the services rendered by that gentleman.

The CHAIRMAN seconded the motion.

A SHAREHOLDER: Has he a large stake in the concern?

The CHAIRMAN: 216 shares. He then put the motion, which was carried unanimously.

Mr. SCOTT having acknowledged his re-election,

The Auditor (Mr. J. Weise) was re-appointed.

On the motion of Mr. RAMSAY L'AMY, a cordial vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN: We are very much obliged to you, and will do all we can to give you a good dividend.

The proceedings then terminated.

Telegraph Construction and Maintenance Company (Limited).

Report of the Directors, to be submitted to the members at the 21st ordinary meeting, to be held on Tuesday, the 3rd day of March, at one o'clock precisely.

The Directors have the pleasure to submit their 21st annual report to the members. The accounts for the year show a net profit of £95,096 6s. 10d. after charging the interest on the debentures. To this sum must be added £66,710 1s. 9d. brought forward from last year, making a total of £161,806 8s. 7d. From this amount is deducted the interim dividend of 5 per cent., paid July 22nd, 1884, amounting to £22,410, leaving £139,396 8s. 7d. to be dealt with. Of this sum the Directors propose to distribute a dividend of £1 16s. per share, absorbing £67,230, being at the rate of 15 per cent., and making, with the amount already paid, a total dividend for the year of £2 8s. per share, or 20 per cent., free of income-tax, leaving £72,166 8s. 7d. to be carried forward to the next account. The operations carried out during the year 1884 have been as follows:—A cable, 875 miles in length, which was manufactured in 1883 for the Eastern Extension Telegraph Company to connect Saigon with Tonquin, in the China Sea, was laid in the month of February. The Brazilian Submarine Telegraph Company's duplicate lines between Madeira and St. Vincent, and between the latter island and Pernambuco, part of which were manufactured in 1883, amounting in all to 3,030 miles, were laid between the months of March and July, and three repairs were effected in that company's original cables during the same time. The Direct Spanish Company's duplicate cable between the Lizard and Bilbao, 473 miles in length, was laid during the month of May. A cable forty miles in length has been laid across the Strait of Sunda (between Java and Sumatra) to replace the one destroyed by the volcanic eruption of 1883. Sundry lengths of cable, amounting to about 660 miles, have also been laid in the Australian and China Seas, to make good the existing lines of the Eastern Extension Telegraph Company, the portions thus renewed having been picked up. These services were carried out at various times between the months of February and August. Short lengths of cable have been manufactured during the year for several telegraph companies; the German Union Telegraph Company's cable between Hamburg and Heligoland has been repaired; and in the month of December, the "Sunk" light vessel at the mouth of the Thames was connected by a cable with the postal telegraph office at Walton-on-the-Naze, as an experiment, for the Corporation of the Trinity House. In view of the wear and tear of some of the Company's ships owing to constant work, the Directors decided that the time had arrived to build a new vessel, of about 1,500 tons, builders' measurement. This vessel is being built by Messrs. Laird Brothers, at Birkenhead, and will be fitted with all the improved appliances for laying and repairing cables. The steamship "Seine" is also being supplied by the same firm with new engines and boilers, and is undergoing a thorough refit. With this exception, the Company's ships and the factories at Wharf-road and East Greenwich are in efficient working order. The retiring Directors are Sir George Elliot and Mr. Philip Rawson, who, being eligible, offer themselves for re-election. The meeting will have to appoint auditors for the ensuing year. Mr. John Gane (of the firm of Messrs. Gane and Jackson) and Mr. James Glegg (of the firm of Messrs. Quilter, Ball and Co.), who retire, offer themselves for re-election.

South-Eastern (Brush) Electric Light and Power Company.

The following circular has been issued by the Directors, dated 21st February, 1885:—

The Directors have read with surprise and regret the report, dated 9th inst., of the committee appointed at the general meeting on the 22nd December last, and the circular of the 14th inst., addressed to the shareholders by W. Hewett, jun., and R. Braithwaite, as, after the conferences which have taken place, they strongly object to the proposal for the immediate liquidation of the Company. The Directors had an interview with the committee on the 4th inst., at which it was proposed that a joint deputation of members of the Board and of the committee should wait on the Directors of the Anglo-American Brush Corporation, and the Directors' letter of the 5th inst., set out in the report of the committee, refers most distinctly to this arrangement. To the astonishment, however, of the Directors, the committee have issued a report recommending the voluntary liquidation of the Company forthwith, and that afterwards an attempt should be made to effect terms with the Anglo-American Brush Corporation. That is to say, first destroy the value of the property you possess and then try to sell it, as under the licenses from the Anglo-American Brush Corporation the act of going into liquidation cancels the concession. This mode of procedure, being so unbusiness like, is not at all likely to be acceptable to the shareholders. The figures summarised by the Committee most imperfectly represent the approximate balance-sheet prepared by Messrs. Price, Waterhouse, and Co., in order to show the position of the Company on the 31st December last. With regard to the Colchester Installation, which was only completed in June last, and is invaluable as evidence of the success of the B.T.K. System, the Directors have always contemplated either the transfer of the business to the Corporation of the Town, or to a local company to be formed for carrying on and extending it; and in case this could not be accomplished, they would seek to obtain permission from the Board of Trade to cancel the license and remove the plant to a locality where electric lighting would be more appreciated. To sell the plant for the "breaking-up value" would entail a heavy and unnecessary loss. The reference to the Consolidated Company would imply that the sum of £15,000, advanced jointly by this Company and the Provincial Company, "is now wholly represented by patents acquired by that company, and by the plant and fittings of the factory in Cow Cross-street;" whereas the committee were distinctly informed that there was also a large and valuable stock of accumulators, finished and unfinished, and of electrical apparatus of various descriptions. The Directors pledge themselves to use their best endeavours to make terms with the Anglo-American (Brush) Corporation; to try to sell the Colchester Installation as a going concern; or, with the consent of the Board of Trade, to remove the plant elsewhere; and then at an early date to wind up the company voluntarily. The adjourned ordinary meeting to receive the report of the committee will be held here on Friday, the 27th instant, at 12 o'clock noon, and if the Company is to be saved from absolute wreckage the shareholders must reject the recommendation of the committee.

Union Electric Light and Power Company.

A general meeting, called by the liquidators of the above Company, was held on the 23rd inst. at St. Stephens's-chambers, Telegraph-street, E.C. The proceedings, however, were private.

NOTES.

REPAIR.—The Compagnie Française notify the repair of their main cable to New York.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 27th February amounted to £3,302.

CIVIL SERVICE ESTIMATES.—In the Civil Service Estimates issued on Thursday appears, under the vote for the Houses of Parliament, the sum of £75 for electric installation!

ELECTRICITY IN AMERICA.—It is said that the Electric Locomotive and Railroad Supply Manufacturing Company, of New York, has been incorporated with a capital of £200,000.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of February were £1,457, against £1,588 in the corresponding period of last year.

THE AFGHAN BOUNDARY QUESTION.—The nearest telegraph station to Sir P. Lumsden's position at Akrobat appears to be Meshed, in Persia, two days' camel ride from our Commissioner's position.

THE ELECTRIC LIGHT AND THE NEW TORPEDO BOATS.—We have reason to believe that the contract for lighting the whole of the new torpedo launches by electricity will be given to Messrs. R. E. Crompton and Co., of Chelmsford.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of the above company are as follow:—Receipts for February, £20,400; 1st January to 28th February, £41,000; corresponding months, 1884, £38,680; 1883, £36,440.

ELECTRIC LIGHT AT CANTERBURY.—It is proposed to use the electric light for the illumination of Canterbury Cathedral. If satisfactory arrangements can be made the new system of lighting will be brought into operation in a few months.

THE INVENTIONS EXHIBITION.—The whole of the electric light leads and cables required in the illumination of the above exhibition will be supplied by Messrs. W. T. Glover and Co., of Manchester, who have obtained the contract.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 27th February were £2,682, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of February, 1885 (including Government subsidies), amounted to £40,114, and to £38,900 in the corresponding period of 1884, showing an increase of £1,214.

THE ELECTRIC LIGHT IN ALGIERS.—We are indebted to our contemporary *Electricité* for the information that the electric light is about to make its appearance in Algiers. The Edison Company have, it appears, made an offer to the municipality of that town, and a commission has been appointed to report upon the project.

THE ELECTRIC LIGHT AT GREENOCK.—At a meeting of the Greenock Town Council, it was intimated that a trial of the electric light had been made at Prospecthill the previous day which was considered very satisfactory, and they hoped within a week to be able to invite the Police Board to witness a trial of the whole system.

CUBA SUBMARINE COMPANY.—The number of messages passing over the lines of this company during the month of February was 3,225, estimated to produce £2,700, against 3,482 messages, producing £3,099, in the corresponding month of last year. The traffic receipts for the month of November, estimated at £2,475, realised £2,326.

PHŒNIX FIRE OFFICE RULES.—We have received the sixth edition of the Phœnix Fire Office rules. These are intended to indicate the conditions under which electric lighting may be safely carried out, and contain many useful hints upon the fastening and insulating of conductors, as well as some equally useful facts for the guidance of workmen and others having charge of installations.

THE SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.—A meeting of this society will be held at the Institution of Civil Engineers, 25, Great George-street, Westminster, on Thursday, 12th March. Papers will be read "On Constant Electromotive Force in an Electric Light Circuit," by Sir David Salomons, Bart., member; and "On Electrical Definitions, Nomenclature, and Notation," by Andrew Jamieson, F.R.S.E., member.

THE SUPPLY OF COPPER.—The quantity of copper imported by England from America has greatly increased during the past three years. In 1882 the quantity was only 745 tons, which rose in 1883 to 9,410 tons, and last year to as much as 17,309 tons. This is the more remarkable as, so recently as 1880, America has had to import from Chili to meet its home demand. Australia is said to have produced about 10,800 tons in 1884, 9,700 in 1883, and 9,800 in 1882.

TELEGRAPH SHIPS AS TRANSPORTS.—The Government have decided to place three other vessels at Suakin, besides the "Calabria," for condensing purposes. They have chartered the Telegraph Construction and Maintenance Company's ss. "Kangaroo," and the ss. "International," belonging to the India Rubber, Gutta Percha, and Telegraph Works, Silvertown. It seems that telegraph ships are preferred on account of their tanks, which are utilised to carry fresh water.

APPOINTMENT.—We have much pleasure in announcing the appointment of Mr. W. H. Massey to the post of mechanical and electric light engineer to the Queen. It will be remembered that Mr. Massey personally supervised and successfully carried out the electric lighting experiments at Windsor Castle and at Buckingham Palace during the past year. The importance of this appointment, as an official recognition of the desirability of establishing such an office, is undeniably great.

MONUMENT TO THE LATE SIR W. SIEMENS.—The monument to the memory of the late Sir William Siemens, F.R.S., has recently been placed over his grave in Kensal Green Cemetery. It consists of a cross of red Aberdeen granite, in which is inserted a medallion of the deceased gentleman in Greek marble. The work has been executed by Mr. A. Bruce Joy, of West Kensington, and has given great satisfaction to Lady Siemens, and to others who have had an opportunity of inspecting it.

LANCASHIRE AND CHESHIRE TELEPHONE COMPANY.—We have just received the February list of subscribers of the above-named company. From it we learn that no less than 3,500 firms in Lancashire and Cheshire have availed themselves of the facilities afforded by telephonic communication; while the number of exchanges already established or in course of formation is about thirty. The company have also call offices in Manchester, Liverpool, Blackburn, Preston, and other towns.

NEWS!—We have to thank our contemporary, *Industria & Invencions*, for the following:—The French Government,

Digitized by Google

already in communication with Senegambia and Tonkin, have contracted for a cable from Zanzibar to Mayotte (one of the Comoro group), Nossi Bé, St. Mary, and Tamatave, which will be ultimately extended to the islands of Réunion and Mauritius. France will thus, says our contemporary, be "in telegraphic communication with *all* her possessions in different parts of the world."

LONG-DISTANCE TELEPHONY.—A trial in the direction of telephoning long distances was made on 5th February, at the Postal Telegraph Company's building, New York, by the Long-distance Telephone Company, working Webster Gillett's patent. Connection was made with Meadville, Pa., a distance of 509 miles, with a satisfactory result. Next, Chicago, over a thousand miles by wire measurement, was connected, and worked well at first, but later something got out of order, and the results were not so satisfactory.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of February, 1885, amounted to £61,784, and to £57,396 in the corresponding period of 1884; increase, £4,388. In publishing these exceptionally large receipts, due mainly to the military operations in Egypt and China, it should be stated that the expenditure will also show a very considerable increase, several important cables having been interrupted during the past month, necessitating the constant employment of all the company's repairing ships. As the cables are duplicated, and in some cases triplicated, the company's revenue has suffered very slightly by the interruptions.

THE ELECTRIC LIGHT IN MYSORE.—The Government of Mysore have granted to the Consolidated Electric Company, manufacturers of the B. T. K. Storage System, the sole right for 55 years of lighting by electricity in the Province of Mysore. The concession permits the company to acquire lands for the necessary works, and to put down plant under or over any public roads or thoroughfares. The Government admits all plant and materials required for the business of the company free of taxes or duties of any description. The principal towns in the province are Bangalore, Mysore, Chitteldroog, Bednore, Seringapatam, and Shemocca. The electric light has been introduced on a very small scale in Mysore.

TELEGRAPHISTS FOR THE SOUDAN.—Fifteen additional volunteers were demanded on Monday last from the Reserves belonging to the Field Telegraph Corps of Rifle Volunteers, and the number was speedily made up. It will be remembered that twelve of this body are now serving in the Soudan, or rather in Upper Egypt, their most advanced station at present being Wady Halfa, the nominal boundary of Egypt proper. This Reserve Telegraph Corps consists of only fifty men, so that more than half of its strength is now on active service. Fresh demands are also being made on the Ærial Telegraph Corps of the Royal Engineers, whose numbers we should imagine are now greatly reduced. The fifteen volunteers are under orders for the Eastern Soudan, and will pr obably sail next week.

LIGHTING OF THE SCHAERBEEK STATION.—It is said that the Belgian Government have decided to light the Schaerbeek Station, which is one of the most important, by electricity. The companies tendering are:—La Société Zurichoise des Téléphones de Zurich; La Compagnie Belge et Hollandaise d'Electricité de Bruxelles; La Compagnie Générale d'Electricité de Bruxelles; and La Compagnie Industrielle d'Electricité de Bruxelles. The engineers of the Administration of the State Railways have been instructed to have the necessary works carried out. They have under consideration the following items:—(1) The system of arc lamps and regulators; (2) the price per lamp-hour; (3) the number of lights; (4) the total expense per hour; (5) the sum total of the estimate. The tenders range from £4,400 to £1,150; the latter, that of the Compagnie Générale d'Electricité has been accepted, and the work is being pushed forward with vigour. The Gülcher lamps and dynamos will be employed.

POLITICAL ECONOMY.—It has been said that the difference between social and political economy is that in the first case a penny is spent to save a pound, and, in the second, a pound to save a penny. The Admiralty refused to grant the very small sum required for the lighting of the "Dreadnought" by electricity before she left England, and, as a necessary consequence, her unfortunate officers and crew are left to grope about as best they can. Oil lamps are not only dangerous and expensive, but ill-smelling and inadequate to the purpose of efficiently lighting a large vessel, while electricity affords a light which is invaluable for service in a man-of-war; is cheap, cool, and inodorous. However, if it is not thought desirable to properly equip one of our finest vessels, such as the "Dreadnought," the Admiralty authorities have, at all events, determined that the "Devastation" shall be so lighted, and as that vessel is about to be laid up in dock, in order to undergo extensive repairs, for an indefinite period, it is no doubt the same thing. Such, at any rate, is the opinion of *Truth*.

THE ELECTRIC LIGHT IN THE NEW HOUSES OF PARLIAMENT AT CAPETOWN.—An interesting experiment was made lately with the lighting of a portion of the new Houses of Parliament by the electric light. The shed and engine which did service in the Good Hope Gardens for the old House of Assembly have been removed to the piece of ground in rear of the Public Library and Museum, and excepting that a more powerful machine has been provided it is only intended at present to utilise the existing appliances. Under these circumstances only the new Assembly Chamber and a few of the offices, such as that of Clerk of the House, and the Speaker's room, will be lit up in this manner. The new machine is one of Edison's "L" dynamos for 150 sixteen candle lamps. There are 108 of these incandescent lamps in the Assembly Chamber, the others being distributed amongst several of the offices. The experiment was decidedly successful, the light being beautifully soft and clear. The electrician now in charge is Mr. Hortsek, from Edison's Company, and he is to be congratulated upon the smoothness with which the experiment passed off. The greatest satisfaction was expressed with the electric light and the appearance of the building under its influence.

ELECTRIC LIGHT IN DWELLINGS.—The portable self-contained electric lamps for use in private dwelling houses made by Messrs. Blumberg and Co., of Cannon-street, are worthy of commendation. These lamps are dependent upon no dynamo engine or working machinery of any kind for the generation of the electric fluid. The current is produced by a small primary battery (Skrivanow), which can be concealed inside a china lamp of ordinary size and pattern. The battery consists of a little oblong box, divided into cells in which there are zinc plates and a packet of chloride of silver, the excitant being a solution of caustic potash. The actual illuminant is one of the little Swan lamps of low candle-power. It will be seen, therefore, that the lamp can be moved about precisely in the same way as if it contained paraffin or colza oil, while it can be introduced into any dwelling house without the necessity for the installation of machinery of any kind. The primary cost varies from 15s. to 50s., according to the size of the battery. According to a rough estimate, it is stated that a light of 25 candle-power will last without being attended to for a space of

twelve hours at a cost of about eightpence. The Skrivanow battery is described in another note.

FOURNIER'S DROMOSCOPE.—The problem of the action of the mariner's compass is singularly complicated by the varying magnetism of the vessel, which causes a deviation of the compass needle. If we let Z = the *cape*—that is to say, the angle formed by the needle of the compass to the axis of the vessel—the deviation of the compass will be seen to result from three distinct deviations—the first, a, constant and independent of the cape; the second variable with the cape z, and is the function of the magnetism of the vessel, the horizontal intensity and inclination—called the *semi-circular* deviation; the third independent of the magnetism of the vessel, and of the globe, and is the function of the geometrical co-ordinates of the pieces of soft iron in the vessel—called the *quadrantal* deviation. The formula generally giving the *true* cape Z in terms of the *false* cape z is then :—$Z = z + D + a + \beta \sin z + \gamma \cos z + \delta \sin 2z + \epsilon \cos 2z$. D being the declination, or the angle formed by the magnetic meridian with the true meridian of the globe; a, a coefficient introduced by the first deviation; β and γ, the relative coefficients of the semi-circular deviation; and δ and ϵ the coefficients of the quadrantal deviation. The instrument called the dromoscope not only registers the various deviations we have described, at the will of the observer, but supplies the correction. The apparatus consists of two needles, pivoted on the same axis; one of them, called the director, shows the false cape z, while the other indicates on a second circle, excentric to the first, the true cape Z. The instrument is, in fact, a contrivance for calculating the deviations of the compass, giving the correction at a mere reading.

THE UNIT OF "R."—Sir. Wm. Thomson expresses his opinion that, at the next congress, 0·2 will be added to the 106 c.m. adopted by the late congress. The following effusion is to be warbled to the air of "The Vicar of Bray." We should have thought that "Ohm, sweet Ohm" would have been more appropriate; but then, you see, we are not poetical :—

In early days I, for a while,
Did soar to truth no higher
Than "equal to a statute mile
Of special copper wire."
But I'm correct, as I'll maintain;
I've always been so far, Sir!
For whatsoever Congress reign
I'll be the Unit of "R," Sir!

When Siemens came it seemed to me
Advisable to swear, Sir,
I was a "METER OF 'Hg,"
One millimetre square, Sir!
But I'm correct, &c.

Then when they crowned great C.-G.-S.,
Lest I should look a dunce, Sir!
I clearly could do nothing less
Than "B A ohm" at once, Sir.
So I'm correct, &c.

Now Paris alters once more still;
So, without hesitation,
I am a "Legal Unit"—*till*
The *next* determination.
So I'm correct, as I'll maintain,
Till Thomson says, "Na! na!" Sir!
Then add "point two," and so again
I'll be the Unit of "R," Sir!

C. W. C.

ELECTRIC CONDUCTIVITY OF SOLUTION OF CARBONIC ANHYDRIDE.—The experiments of Hittorf on the migration of the ions during electrolysis point to the importance of electric functions in deciding the chemical constitution of solutions of gases in water. Kohlrausch has also proved by experiments on the electric conductivity of solutions of ammonia that these do not contain the hypothetical combination—ammonium hydrate. The following are the principal results of experiments on solutions of carbonic anhydride under increased pressures, varying from 1 to 25 atmospheres. (1) A solution of carbonic anhydride in water forms one of the worst conductors known, the conductivity, under normal conditions, being about $\frac{1}{20}$th of that of spring water. (2) Although it is commonly assumed that a solution of carbonic anhydride in water contains the hypothetical carbonic acid, H_2CO_3, in that it possesses an acid reaction, yet, according to Kohlrausch's experiments, the conductivity of such a combination should be equal to $202{,}000 = 10^{-10}$ C.-G.-S. units, or more than a thousand times greater than the highest value found. (3) Change of pressure produces no alteration in the conductivity, which would appear to show that the carbonic anhydride is liquefied in the process of solution. (4) Carbonic anhydride is soluble in water at the temperatures above its critical point. If, then, the solution were a mixture of water and liquid carbonic anhydride, it is probable that irregularities in its conductivity would be observed at the critical point; but this is not the case. (5) The curve of the conductivity as a function of the temperature is analogous to the curves described by Kohlrausch for oxalic, tartaric, and ascetic acids, in that it ascends rapidly for increase of dilution. This would seem to point to an analogy of constitution of a solution of carbonic anhydride in water with these acids.

TELEGRAPH POSTS.—According to the *Daily News*, the nine hundred miles of additional telegraph lines required outside of London for the cheaper service in August have robbed the Norwegian pine forests of some 20,000 trees. English larches used to be employed for telegraph posts, but they proved to be sadly wanting in durability. The wood was of too close a grain to permit of its being impregnated with creosote, but yet incapable of resisting the effect of moisture for any great length of time. Larch, therefore, has been discarded, and all our telegraph poles are now imported from Norway. In America they appear to have given the closest attention to this subject, for it has been found that dividends are very largely dependent on the durability of poles. They use various kinds of wood, cedar by preference, and it is said that the durability of a pole depends to some extent on the time of year in which it is cut down. A sound cedar post felled in winter, when the sap is low, will last for sixteen years. A spruce pole will last seven years only under the best of circumstances. The soil in which they grow is said also to have considerable influence on the lasting powers of telegraph poles, and no doubt also much depends on the soil and situation in which they are planted for service. In America it has been found that the whole of their lines want completely renewing every ten or fifteen years at the utmost. The importance of the supports of a telegraph line becomes particularly obvious when it is remembered that the breaking of a post involves not merely the necessity of renewing it, but also broken wires and interrupted service by throwing the various wires one across the other. It seems probable that by and by Norwegian pines in this country will give place to iron posts, which, of course, may be made somewhat more ornamental than bare pine poles, and possibly would prove sufficiently durable to more than counterbalance the extra cost. This is a point, however, which at present seems to be doubtful. An iron post will cost four times as much as a

Digitized by Google

wooden one, and how many times longer it will last there is at present no sufficient evidence to show. A four-fold initial outlay is a matter that is not to be altogether overlooked.

A NEW INDUCTION TELEGRAPH.—An ingenious apparatus has been designed by Mr. Phelps, of New York, by means of which communication may be established with a train whilst the latter is in motion. The contrivance is based upon the phenomenon of induction between two parallel wires. A copper conducting wire is arranged in the centre of the railway track; another wire runs along the bottom of the railway car, with which wire he connects a telegraph sounder located within the car. Whenever an electrical signal is sent through the track telegraph wire, it produces by induction a corresponding current in the wire attached to the car, and this current works the sounder, thus delivering the message; or a message may, in the same manner, be transmitted from the car to the railway station. The track wire, whence the induced current originates, is placed by Mr. Phelps in a wooden casing at a point equi-distant from the rails over which the cars pass. This casing does not rest directly upon the sleepers, but on blocks of wood, four inches long, two inches wide, and thicker or thinner according as the sleepers are higher or lower in the centre. Four men, it is said, will fit and lay two miles of these in a day's work, and with such nicety that the top of the box containing the conductor will be a trifle below the same plane as that in which the top of the rails lie. At points where branch or other roads cross the main line, the conducting wire passes, in an india rubber tube, under the interfering rail. The electrical arrangements on the car are as follow:—Running the entire length of the car between the forward and rear cars is the induction coil. There is a two-inch iron pipe, which is suspended so as to hang seven inches above the track conductor that rests upon the sleepers. Within this suspended iron pipe is a 1¼ india rubber hose, which in turn contains ninety convolutions of copper wire, insulated with paraffin. This copper wire extends round and round through the suspended iron pipe and up along the upper part of the car, and forms a circuit a mile and a half in length. The pulsations which pass over the track wire when taken up by the induction coil are received by an ingeniously-made polarised relay, the action of which is in no way disturbed by the motion and jarring of the train. From this instrument the received impulses are conveyed to an ordinary telegraph sounder, worked by a local battery. A company has been formed to exploit this useful invention.

THE THERMOMICROPHONE. — The new microtelephonic system of Dr. Ochorowicz, to which allusion has already been made in our columns, is composed of two instruments which, in a paper read during the past month before the Société Internationale des Electriciens, were thus described. The magnetic receiver differs from all other apparatus of its kind: (1) By the employ of two vibrating plates equally polarised by the same magnet, and embracing the two extremities of the coils; (2) by the mode of attachment of the telephone case which, instead of being immobile, also vibrates, and is fixed only by means of the second vibrating plate. An examination in detail demonstrates the perfect utilisation of the magnetic field and the absolute concordance of the vibrations of every part of the system. The thermomicrophone is, it is averred, the most powerful of all the telephonic transmitters. It reproduces sound in a loud tone even when the speaker is to some degree distant from the instrument, while music and song can be so transmitted as to be heard by a large assemblage of people. The microphones with which we are acquainted may be classified as follows:—(1) The Edison, which embraces all the transmitters acting by *pressure;* (2) and the Hughes, comprising all those which act by means of vibrations, and which have always a certain number of carbons, variously disposed. The thermomicrophone occupies an intermediate place, being acted upon partly by vibrations and partly by pressure. The principal feature of the system, however, is the introduction of heat. Generally speaking, all microphones are more or less heated during action, and the thermal effect increases their sensibility; but there is one great disadvantage attending it—the heat renders the apparatus irregular. The difficulty has been to regulate the instrument so as to allow for the generation of heat and guard against its disturbing influence. The action of the microphone is, as has been said, irregular; its resistance is then almost nothing, but from the moment that a current of 18 to 20 milliamperes passes through it, it becomes heated, its resistance is augmented (to about a mean of 200 ohms), and the apparatus will be found regulated for transmission. Under these circumstances it is evident that the exterior temperature will assist or impede the effective working of the transmitter; but by the application of a layer of insulating material in the interior of the microphone itself, Dr. Ochorowicz has been able to maintain a temperature of from 13° to 39°, which is sufficient for all practical purposes. At the conclusion of the paper the thermomicrophone, actuated by five Leclanché cells, was placed in a room on the third floor of the building, and the receiver upon a table in the conference room some 50 metres distant. The result seems to have given great satisfaction, the articulation of the instrument being so distinct that the three hundred members of the society were enabled to hear it with perfect ease.

ARCHITECTURAL EXHIBITION.—An architectural and building exhibition, organised by the new Society of Architects, has been held during the past week at the Floral Hall, Covent Garden. The chief novelty in electrical appliances seems to be a portable invalid's call, consisting of a case containing a Leclanché battery, a bell, a push, and several yards of double insulated wire. It is intended to place the apparatus temporarily where the bell is required to ring, and lead the push to the bed of the invalid. The arrangement exhibited by Julius Sax is distinguished by careful construction. One of those shown by Eck, Callow, and Co. was lately supplied to H.R.H. the Duchess of Albany, and has the push sunk in a convenient form of oblate spheroid ball, so that it is not likely to be actuated unintentionally. The variety shown by W. Pressland is distinguished by great cheapness; and he has devised a pear-shaped ball with duplex action, with the ordinary push at the bottom, and also capable of being actuated by pulling down like an ordinary bell-pull. Julius Sax also shows a tell-tale clock for checking the rounds of watchmen. The clockwork turns a drum covered with paper, divided into hours, &c., and also into spaces corresponding with various parts of the building to which wires are led, terminating in pushes. The watchman has to touch these pushes in succession, thus marking a dot upon the corresponding space, and producing a permanent record of his rounds. There is an electric water gauge for registering, inch by inch, at the pumping station, the rise and fall of water in a tank or reservoir, and ringing a bell when the water reaches the highest or lowest point. An electric billiard marker has pushes in all the sides of the table, for use in private houses. Eck, Callow, and Co. show Brown's automatic fire alarm, in which, on the melting at 160deg. F. of a fusible band, a bell rings, a visible signal is shown, and, if it be wished, a Bengal light is ignited. Milton Syers exhibits, for

Digitized by Google

the first time, a syphon cistern and water-waste preventer, in which the valve for allowing the confined air to escape, and the water to flow, is opened by a magnet drawing down its armature on contact being made. Paul Pfleiderer had on view his "Universal" kneading and mixing machine, which is used, among other purposes, for the paste for which electric light carbons are made. The exhibition was lighted—we were going to say—by the Maxim-Weston Electric Company, but, unfortunately, the electric light was found wanting when most required. The President's *conversazione* was held in semi-darkness; and it was not until eight o'clock on Tuesday that unfortunate exhibitors, not provided with other means of illumination, could show off their wares to advantage. We heard vaguely of a fly-wheel breaking and of a piston giving out; but, if so, why was not the engine duplicated, so as to provide for emergencies? We were at considerable pains to ascertain the real cause of failure, but were invariably met with the inertia of resistance, to say the least. There are six Maxim-Weston arc lights in the Floral Hall, and one outside; and there may be more that we do not know of. There are also two rows of ten Maxim incandescent lamps in the temporary theatre; and we believe there are a few in the engine room, into whose sacred precincts we were not permitted to set foot. And these lights are—or should be—maintained by two arc and one incandescent dynamos. We wish the Society of Architects better luck next year in their lighting arrangements.

Influence of Electricity upon a Liquid Film.—A further account of the experiments of Professors Reinold, F.R.S., and Rücker, F.R.S., as to the influence of an electric current in modifying the rate of thinning of a liquid film, have recently been published in the *Philosophical Magazine*. One of the primary objects of this investigation, of which a description was published in *Proceedings* of the Royal Society in 1877, was the determination of the electrical resistance of films. A Wheatstone bridge was employed for this purpose, and a current was passed through the film only at a moment when observation was required. It was then seen that the films became black, and measures of their resistance while displaying this colour were successfully obtained. Afterwards continuous currents were employed, and the difference of potential between two fine wires thrust into the film was measured by an electrometer, and compared with the resistance between two other points in the same circuit, separated by a known resistance. The results obtained were not altogether of a satisfactory nature; but the later experiments are interesting as showing the behaviour of the films, and the nature of the colours evolved under the influence of the electric current. The liquid employed consisted either of a solution of potash, soap in water, or of *liquide glycérique*, containing a certain portion of nitre to increase its conductivity. The films had the form of vertical cylinders; the upper and lower ring supports being of platinum, and about 33 millimetres in diameter. The cylinders were, as a rule, from 30 to 40 millimetres in length, but occasionally other lengths were under examination. Three films were observed simultaneously, two of them being in one glass box, and the third in a separate glass box. The two that were together were supported by platinum rings identically alike, and sharply beveled at the edge; the edges of the supports of the third were much thicker, and were rounded. It could thus be ascertained whether any difference in the behaviour of the films was due to the form or thickness of their supports. No such difference was observed. Each of the film boxes was placed in the centre of a water tank with glass sides, in order to prevent rapid changes of temperature. In all cases the films were surrounded with air saturated with the vapour of the liquid of which they were made. The constancy of the hygrometic state of the air, and that of its temperature were indicated respectively by a hair-hygrometer, and a thermometer inside the glass case. The films were blown with air, which was first dried and then passed over some of the soap solution in a wide tube. The state of the air inside the film was thus approximately the same as that on the outside. The current employed was generated by a Siemens dynamo, and passed through a sensitive reflecting galvanometer, the deflection on the scale measuring approximately the strength of the current. This varied from about 100 micro-amperes to 0·5 of a micro-ampere. Under these conditions it was seen that in less than a minute after the adjustment of the film (potash-soap solution, without glycerine, 40 millimetres) to the cylindrical form, narrow rings of colour appeared, and white of the first order of Newton's rings was soon seen at the top, generally bordered by a deep band of blue of the second order. The coloured portion of the film extended only 10 millimetres from the top. In from eight to 15 minutes from the moment of formation of the film, a black film appeared, and slowly extended downwards. The behaviour of the films under the influence of the current was now observed. With a solution of potash-soap and a film 40 millimetres long, through which the current was passed from the moment of its formation, it was found that broad bands of colour formed and spread with great rapidity, soon occupying the whole area of the film. After six minutes the current was 2·6 micro-amperes. In eleven minutes there was a ring of black, which increased in three minutes to 3 millimetres. Next, a film of 40 millimetres was taken, which had thinned until 2·5 millimetres of black were formed. Following the black was a band of deep blue. A downward current of 5·18 micro-amperes was applied. The blue changed to white, the black not being altered. After nine minutes the black was still of the same breadth, and the white had increased to 16 millimetres, the current being 4·06 micro-amperes. In two minutes after breaking the circuit the white had changed to black, the extent of which had become 19 millimetres, or nearly the whole length of the film. This and similar observations showed that a downward current had the remarkable effect of swiftly thinning that part of the film which was thicker than the black, but did not necessarily affect the latter. The film, however, was put into such a state that, on the cessation of the current, the development of the black proceeded at a rapid rate. With a downward current of 6·2 micro-amperes the black entirely disappeared after one minute, being replaced by white; and the current rose to 6·5 micro-amperes. The latter had the effect of destroying the black and increasing the conductivity of the film. With a film 30 millimetres long, to which a downward current of 24 micro-amperes was applied from the beginning, the white extended more than halfway down, after ten minutes, and the current fell to 2·5 micro-amperes. The circuit was then broken and the white turned to black so rapidly that the entire transformation was effected in less than one minute. Under the influence of the upward current the black was always destroyed, and, where previously existing, replaced by white; the current generally increased in intensity up to a certain limit. At certain stages of the film's existence a very feeble current was sufficient to destroy the black. One very interesting experiment was performed upon two films, each 30 millimetres long, which were formed side by side. The current was divided and passed up one and down the other film. The effect was most striking. In twelve minutes, when one of the films broke, there were 15 millimetres of black in the one, while the other was thick and colourless, and liquid was streaming from the top of it.

ON THE DESIGN AND CONSTRUCTION OF DYNAMOS.

BY GISBERT KAPP.

(CONTINUED FROM PAGE 309.)

[*Errata.*—On line 18 of the last article, page 307, READ $\frac{1}{850}$ and $\frac{1}{800}$ for $\frac{1}{150}$ and $\frac{1}{200}$.]

It remains yet to be considered whether a machine constructed as shown in Fig. 1, but without iron, could excite itself—that is, act as a dynamo. The answer must be in the the negative, as can easily be shown. Suppose the coils *a*, *b*, *c*, *d*, were put in series with the armature wires *e f*, and admit for a moment that the principle of mutual accumulation, as in the ordinary dynamo, would come into action, what would happen? A weak current in the field wires would induce a proportionately weak current in the armature wires; this would reinforce the former, which would again act on the armature, and so on to infinity, since the induced current is always proportional to the inducing one and the resistance of the whole apparatus is a fixed and finite quantity. The above admission leads, therefore, to the absurd result that a dynamo without iron can give an infinite current, and we must conclude that no mutual accumulation can take place, and therefore the apparatus cannot act as a self-exciting generator of current. This follows, also, from a closer study of the interaction between the various wires. To simplify matters we will assume the most favourable case, viz., that all the lines between *a* and *d*, and similarly all the lines between *b* and *c* are eliminated, and only those passing vertically between *a* and *b* and *c* and *d* remain, which are all favourable for generating a current in the armature wires. On this supposition the current in *e* will be started the moment when this wire passes the radius connecting *a* with the centre. Now, the current starting in *e* reacts on the wire, *a* creating a current in the opposite direction, and therefore weakening the original current. The same takes place when *e* passes the other field wires, and the result is that no current can be generated. But if this reaction of the armature wire on the field wire could by some means be prevented, the machine could be made to work. To do this, it is required to prevent the lines of force round the armature wire from reaching the field wire, without, however, preventing the lines of force round the field wire from reaching the armature wire. The only method known at present for effecting this is by an iron screen interposed between the two sets of wires—in other words, by employing iron pole pieces. Here, then, we have two very good reasons for employing iron in the construction of field magnets—the first, as already stated at the end of the last article, is that the magnetic resistance in the path of the lines of force produced by the field wires is diminished, and a given amount of exciting power is made to yield a larger number of lines; and the second is that the iron protects or screens the field wire from reaction on the part of the armature wire.

Up to the present we have tacitly assumed the central space between the armature wires to contain only air or other non-magnetic substance, but it will be evident that if we fill it with iron, we shall still further reduce the resistance in the path of the lines, and get on that account also an increase in the number of lines which go across the armature. But since the electromotive force, and consequently also the current, depends on the number of lines of force (or, as it is sometimes put, on the strength of field) we arrive at the broad fact that to obtain the greatest electrical output with machines of the type described we should have a sufficient mass of iron both in the field-magnets and also in the armature. The same can be shown for machines of the Gramme type, whether the armature be cylindrical or ring shaped. It might, perhaps, be thought that, since this fact is so generally known, all the above arguments might well have been omitted, and these articles might have begun with the axiom, "In a good dynamo there should be plenty of iron." But then it would have been necessary to explain why; and that would have forced us to introduce at the beginning the question of magnets generally. Now such terms as "free magnetism," "strength of pole," "magnetic moment," "total magnetism," &c., which are generally employed when we talk of magnets, are very objectionable, because to different people they have a different meaning, and cannot be so easily fixed numerically as can the simple conception of lines of force. Moreover, the employment of a nomenclature itself somewhat indefinite must sooner or later lead to loose reasoning, and should be avoided on that ground alone if on no other. According to our way of looking at the question the proper function of the field magnets of a dynamo is not to have the greatest possible magnetic moment, or free magnetism, or total magnetism, &c., but simply to facilitate the creation of lines of force belonging to the field wire, and to protect the latter from reaction on the part of the armature wire. If, as a necessary consequence, the poles of the field magnets and other portions as well become strongly magnetic (as the word is usually understood), this is a result but not the cause of the lines of force.

It will be useful to see what connection exists between lines of force and the above terms relating to magnetism, at least as far as a definite meaning can be attached to them. In making the comparison we shall assume all the lines to have equal force, no matter how their number may vary in different places. According to this conception the free magnetism or strength of pole of a magnet would be represented by the number of lines emerging from that pole. The magnetic moment would be defined as the product of number of lines on either end of the magnet multiplied by the distance between the two surfaces at which the lines enter and leave the magnet. If the lines do not all enter and leave the magnet at the ends, but partly also at the sides, as is generally the case, the magnetic moment is the sum or integral of these products taken separately for each line or group of lines. Intensity of pole can be expressed as the number of lines emanating from one square inch of polar surface, and strength of field as the total number of lines passing between two opposite polar surfaces. In the same way the intensity of the field in any particular place is expressed as the number of lines of force passing through one square inch of cross section at that place. It should be remarked here that electro-magnetic measurements are generally given in C.-G.-S. units, but to make the formulæ given below directly applicable in the drawing office and workshop the inch has been retained as the unit of length.

In a dynamo those lines of force which are instrumental in producing E.M.F. pass between the polar surfaces and the armature; all other lines are useless or detrimental to the working of the machine. The greater the number of useful lines the higher will be the E.M.F. produced with a given number of coils on the armature and at a given speed. Our aim should therefore be to produce a maximum number of lines. The question now presents itself, how can the number of lines be calculated beforehand if the dimensions and other constructive particulars of a dynamo are known? Experimentally, the author has found that for low-exciting powers the number of useful lines can with a reasonable degree of approximation be expressed as the quotient between exciting power and magnetic resistance. This alone does, however, not solve the question; it merely shifts it over to the following problem:—How can the magnetic resistance of a given dynamo be computed? Before entering into this subject in detail it will be instructive to point out the analogy which exists between this conception of magnetic resistance and Ohm's law. In fact it is Ohm's law applied to the magnetic circuit. For electromotive force put exciting power, for current put number of lines of force running across the polar surfaces, and for electrical resistance put magnetic resistance, and the analogy is perfect. We can even go a step further, and establish an analogy between internal and external resistance as applied to a set of cells and to an electro-magnet.

Let in Fig. 2, A B and C D be two rows of cells placed opposite each other, and join the ends B and C by a wire of small resistance *r*, and the ends A and D, which we consider as the poles of the two sets of cells, by a somewhat greater resistance, R. Let there be *n* cells in each row, and let the internal resistance of each cell be ρ, and its electromotive force *e*. If the total difference of potential between A and D be E, the current flowing (if we have no leaks) will be

$$c = \frac{E}{R} = \frac{2ne}{2n\rho + r + R}$$

Digitized by Google

Since we are only dealing with a difference of potential, we may fix the absolute potential of one point of the system at any convenient level. Say we assume the potential of D to be zero. Then the absolute potential will be

In C ..... $ne - cn\rho$
In B ..... $ne - cn\rho - cr$
In A ..... $2ne - 2cn\rho - cr$

Now, it will be evident that the potential in C must be greater than that in B, the difference being cr; and since the potential increases from B towards A and decreases from C towards

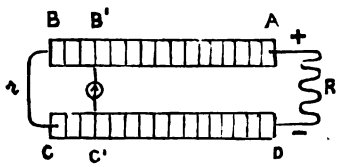

FIG. 2.

D, there must exist on the former row of cells somewhere a point B', where the potential is $ne - cn\rho - cr + \frac{1}{2}cr$, and on the latter row of cells somewhere a point C', where the potential is $ne - cn\rho - \frac{1}{2}cr$. If we join the points B' and C' by a galvanometer as shown, the latter will give no deflection, whilst if we shift the galvanometer with its attachments to the right or left of this position it will show a deflection in one direction or the other. The position of equilibrium will be the nearer to the poles the greater the resistance of r, and if it be desired to get a maximum of current through R, where it does useful work, the resistance of r should be as small as possible. Practically the cells between C' and C and between B and B' are useless.

Now for the analogy of the magnetic circuit. Let, in Fig. 3, A B C D be the magnet excited by coils as shown. The armature is placed between the poles A and D, and is traversed by lines running N — S, as indicated by the arrows. Let R be the resistance of the armature, and r that of the yoke B C, and the analogy will be apparent. In a perfect machine the lines should run right round inside the iron from R to S A B r C D N and back to R. In doing so the lines experience a certain resistance, partly due to having to leap across the air space between the poles and the core of the armature, partly due to the core itself, and partly due to the magnet. If we make the arms of the magnet long and thin we increase the internal resistance; and if we make the yoke r of small cross section we also increase the internal resistance. The formulæ given for the battery circuit are directly applicable in this case if by e we denote the exciting power per lineal inch of magnet core, by ρ the magnetic resistance of one inch of core, and by

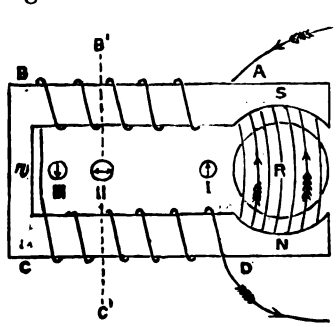

FIG. 3.

n its length in inches. If we place a small compass in position I, the N of the compass will point at arm A B, and if we move the compass to the left it will continue to point the same way, but with decreasing force, until a position II is reached, where the needle of the compass is undecided which way to point. In this position there are evidently no lines of force, or, if there be, they must run in all possible directions. If we move the compass still further to the left, the N will point towards C—that is, in the opposite direction to the first. The position II on line B' C' corresponds to our experiment with the galvanometer on the cells, the only difference being that here we have the air as a conducting medium, whilst there we had to touch the cells with the wires from the galvanometer to get an indication. The lines of force leak across from one arm to the other, and so influence the little compass. It will be easily understood that as far as the armature R is concerned, that portion of the winding which is to the left of the line B' C' is absolutely useless; its only use is to overcome the resistance of the yoke r. The position II can be found in any dynamo while at work. Take a small compass, such, for instance, as is made as an ornament for watch chains, and pass it slowly between the two arms from the armature towards the yoke. There will be found one position where the compass seems quite undecided which way to point. In cast-iron machines with thin yokes this position will be found several inches from the yoke, but in wrought-iron machines with very thick yokes it will be found so near the yoke that it is sometimes difficult to detect it at all. From what we have said just now about the coils to the left of the line B' C', it will be seen that machines with long magnets and thin yokes might be improved by shortening the magnets and joining them by much heavier yokes.

(TO BE CONTINUED.)

THE MOST ECONOMICAL POTENTIAL DIFFERENCE TO EMPLOY WITH INCANDESCENT LAMPS.*

BY PROFESSORS W. E. AYRTON, F.R.S., AND JOHN PERRY, M.E.

(CONTINUED FROM PAGE 309.)

Since writing the article in your issue for February 21st, one of our students, Mr. Robertson, has with praiseworthy energy been making some efficiency experiments on Edison lamps obtained from France, and by trial he has found some that give 16 candles at about 100 volts, and are therefore presumably of the same type as those employed in the life experiments given by M. Foussat in your issue for January 31st.

Mr. Robertson's experiments on one such lamp are as follow:—

TABLE I.

Candles or θ (v).	Volts or v.	Watts.	Candles or θ (v).	Volts or v.	Watts.
3 ...	84	... 56·62	18 ...	101·5	... 92·37
4 ...	87	... 63·51	20 ...	103·6	... 96·66
5 ...	87·8	... 66·03	22 ...	105·4	... 100·13
6 ...	90·5	... 69·05	24 ...	107·5	... 104·28
7 ...	93·5	... 75·74	26 ...	109·2	... 108·11
10 ...	96·75	... 79·34	28 ...	110	... 111·10
11 ...	97·61	... 81·01	30 ...	111·4	... 113·63
12 ...	98·04	... 82·35	35 ...	114	... 118·56
14 ...	98·9	... 85·55	40 ...	115·2	... 122·11
16 ...	100·6	... 90·54			

We are therefore now in a position to take up the problem in a more direct manner, without making any assumption beyond this—that Mr. Robertson's 16-candle 100-volt French Edison lamp is of the same kind as M. Foussat's 16-candle 100-volt French Edison lamp.

Solving the problem graphically in the way previously described, and using the same values of p, n, and H, viz., cost of a lamp, 5s.; number of hours of burning per year, 560; and annual cost of an electric horse-power for these 560 hours, £5, we obtain the curve. A A A (see diagram, p. 348) represent the cost per candle per year as regards renewal of lamps, B B B the cost per candle per year as regards power, and the resultant curve C C C the total cost per candle per year.

The minimum value of this cost appears from this curve C C C to be at about 101·4 volts, and to then equal about 11d. per candle per year.

If the potential difference be maintained constantly down at 98·7 volts, or up at 104 volts, then the cost becomes 1s. per candle per year. It will also be seen from the curves that the yearly cost for renewals of lamps is but a small fraction of the total yearly cost as long as we are using potential differ-

* Read at the Physical Society, February 28, 1885.

Digitized by Google

ences of not more than about 100 volts; so that when using, with these lamps, this or a lower potential difference the actual sum paid for the lamps is not so very serious an item in the yearly lighting bill. But if, on the other hand, we maintain a potential difference of, say, 104 volts constantly at the terminals, then the lamp renewals represent, in our particular case, nearly one third of the yearly expenditure, and consequently any change in the price of lamps becomes extremely important.

We find that the simplest expression for the candle-power of this incandescent lamp in terms of volts is

$$\theta(v) = a\,(v-b)^3 \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Thus, for example, it will be found that if the cube roots of the values of $\theta(v)$ given in the preceding table are plotted with the corresponding values of v as co-ordinates of points on

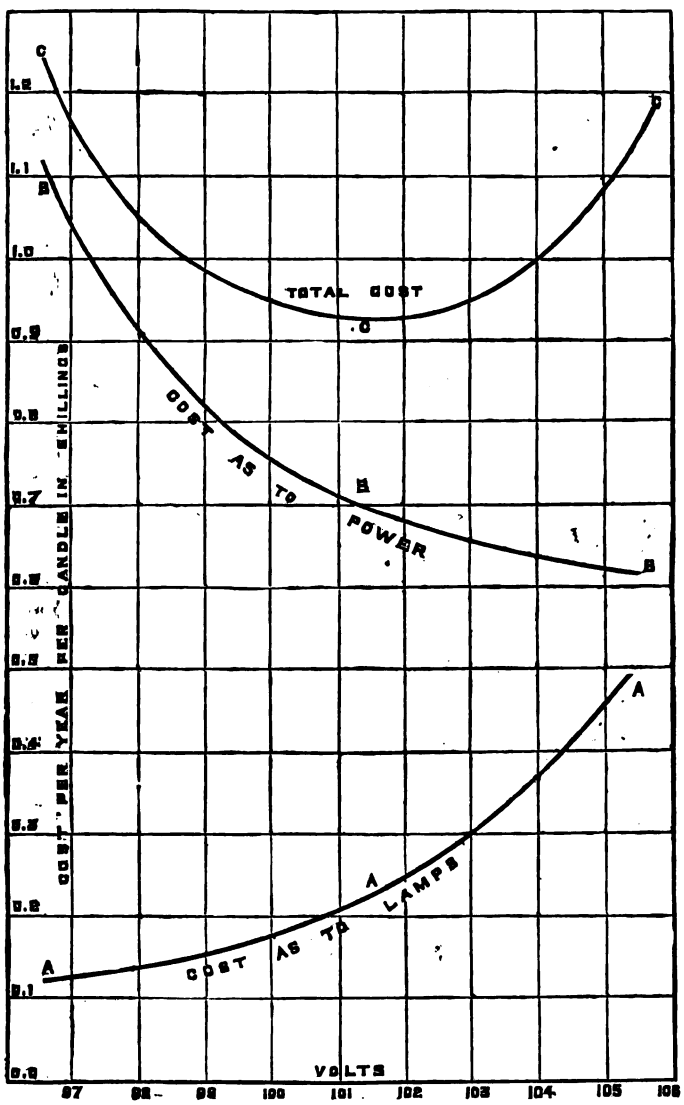

DIAGRAM FOR A 16 CANDLE 100 VOLT EDISON LAMP.

squared paper, the points lie in no regular curve so nearly as on a straight line, discrepancies being apparently due to an error of observation, which errors of observation follow a periodic law which may be of interest physiologically. Or it may be that the two slight waves in the curve on each side of the straight line are due to there being a place of contra reflexure at the part of the curve when we are examining it.

For the particular lamp in question we find that

$$a = 0{\cdot}0002621$$
$$b = 62{\cdot}12$$

or if the law remains true for a less number of volts than 84, which is the lowest used in this experiment, then when $v = 62{\cdot}12$ the light, or $\theta(v)$ becomes nought.

We do not, however, find that the cube roots of the candle-power of all sorts of incandescent lamps follow a line function of the difference of potential at their terminals, for examining the results of experiments that have been made with various types of lamps, we find that with the first four of the following set of lamps, the law

$$\sqrt[3]{\theta(v)} \propto v - b$$

is very nearly true.

1. A Lane Fox lamp ..... from 50 to 80 volts.
2. A British Electric Light Company's lamp ..... „ 50 to 68 „
3. An Edison "7 B" 8-candle lamp ... „ 45 to 63 „
4. A old Swan lamp..... „ 40 to 64 „
5. A low resistance 8-candle Swan lamp „ 16 to 40 „

whereas with the next five lamps it is not so true, although for half the range the law might be regarded as true in all the cases.

6. A Maxim lamp ..... from 42 to 57 volts
7. A Maxim lamp ..... „ 35 to 110 „
8. An old form Swan lamp ..... „ 25 to 54 „
9. A high resistance Swan lamp ..... „ 45 to 90 „
10. An Edison B 8-candle lamp..... „ 36 to 85 „

We may here mention that we have found the following plan very useful in helping us to draw correctly a curve at a place where there is a sudden bend and an absence of points, determined from experiments, to guide us in drawing the curve. Instead of plotting x and y, and obtaining a curve which it would be very difficult to draw correctly, we may be using some easily derived function of y obtain points which obviously lie on a curve which it is easy to draw. Thus we may plot $\sqrt{y}$ and x, or $y^{\frac{1}{3}}$ and x, or $\log y$ and x. When the curve connecting y and x is not asymptotic to the axis of x, but to some line parallel to this axis, it is obvious that there is a greater likelihood of obtaining simple curves by plotting $\sqrt{y \pm a}$ and x, or $(y \pm a)^{\frac{1}{3}}$ and x, or $\log(y \pm a)$ and x, where a is some constant obtainable by inspection, than by simply plotting the function of y above.

The following table gives M. Foussat's lives in terms of v and the corresponding values which we have calculated of $\log f(v)$, $\log \theta(v)$, and of $\log f(v)\,\theta(v)$, from the values of $\theta(v)$ given in the previous table :—

TABLE II.

v.	$f(v)$.	$\log f(v)$.	$\log \theta(v)$.	$\log f(v)\,\theta(v)$
95	3595	3·5557	0·9729	4·5286
96	2751	3·4395	1·0119	4·4514
97	2135	3·3294	1·0485	4·3779
98	1645	3·2161	1·0851	4·3012
99	1277	3·1062	1·1199	4·2261
100	1000	3·0000	1·1556	4·1556
101	785	2·8949	1·1898	4·0847
102	601	2·7789	1·2216	4·0005
103	477	2·6785	1·2531	3·9316
104	375	2·5740	1·2852	3·8592
105	284	2·4533	1·3152	3·7685

When $\log f(v)\,\theta(v)$ and v are plotted as co-ordinates of points these points are found to lie so nearly on a straight line that the formula

$$\frac{1}{f(v)\,\theta(v)} = 10^{0{\cdot}07545\,v - 11{\cdot}697} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

is found to be true with considerable accuracy, and such a formula lends itself with great ease to calculation.

It is quite true that we might have obtained a still more accurate formula than (2), since, as published by Mr. Wright, one of the members of our class, in *The Electrician* for February 21st, the logarithm of the life of a lamp is shown to be a line function of the difference of potentials at which it is worked.

We may, in fact, with this particular type of lamp, put

$$f(v) = 10^{14 - 0{\cdot}11\,v} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

with very great accuracy indeed.

Combining this with (1), we obtain as a more accurate formula

$$\frac{1}{f(v)\,\theta(v)} = \frac{1}{a}\,10^{0{\cdot}11\,v - 14}\,(v-b)^{-3} \quad . \quad . \quad . \quad (4)$$

Digitized by Google

But, unfortunately, this more accurate formula does not lend itself to mathematical calculation, whereas that given in (2) is very suitable for this, and has a sufficient degree of accuracy for our purpose. In using (2) we are really using for the candle-power

$$\theta(v) = 10^{0.03455\,v - 2.303} \quad . \quad . \quad . \quad . \quad . \quad (5)$$

instead of (1).

It will be also found that from 95 to 105 volts, the range of volts given in Table II., the values of $\phi(v)$ or volts per candle-power, when corrected for errors of observation, satisfy with considerable accuracy the equation

$$\phi(v) = 3{\cdot}7 + 10^{8.007 - 0.07667\,v} \quad . \quad . \quad . \quad (6)$$

If, however, we take the whole range of values given in Table I., then it will be found that the equation

$$\phi(v) = 2 + 10^{4.424 - 0.03793\,v} \quad . \quad . \quad . \quad . \quad (7)$$

is better satisfied than (6).

The following Table III. gives the numbers we have actually employed in making these calculations.

TABLE III.

v.	$\sqrt[3]{\theta(v)}$ corrected.	$\theta(v)$ corrected.	Watts corrected.	Watts per c.-p. $\phi(v)$.	$\log\{\phi(v) - 2\}$
84	1·4	2·744	56	20·408	1·2650
86	1·53	3·582	60·15	16·79	1·1700
88	1·66	4·574	64·25	14·27	1·0888
90	1·786	5·7	68·4	12·0	1·0000
92	1·914	7·0	72·6	10·37	·9227
94	2·044	8·55	76·85	9·0	·8451
96	2·175	10·28	81	7·882	·7695
98	2·3	12·167	85·15	7·0	·6990
100	2·428	14·24	89·3	6·271	·6305
102	2·556	16·69	93·5	5·6	·5563
104	2·682	19·29	97·8	5·07	·4871
106	2·81	22·188	101·9	4·593	·4138
108	2·94	25·412	106	4·172	·3369
110	3·065	28·79	110·1	3·824	·2610
112	3·195	32·61	114·25	3·504	·1772
114	3·32	36·594	118·3	3·233	·0910

Using (6) and (2), the total cost of one candle per year is

$$p\,n\,10^{0.07545\,v - 11.697} + \frac{H}{746}\left(3{\cdot}7 + 10^{8.007 - 0.07667\,v}\right).$$

This is a minimum when

$$v = 110{\cdot}66 + 6{\cdot}574 \log \frac{H}{p\,n}.$$

Hence, taking $p = 0{\cdot}25$, $n = 560$, $H = £5$, we find

$$v = 101{\cdot}15 \text{ volts.}$$

Using (7) and (2), we shall find in the same way that the minimum is obtained when

$$v = 101{\cdot}46 \text{ volts,}$$

which minimum values of v agree very closely with that previously determined graphically.

One very important problem in connection with incandescent lamps, and one that cannot yet be regarded as solved, is the determination of the life of a lamp for any given number of volts from experiments made either on the efficiencies at several different potentials, or from experiments on the life made at so high a potential difference that the life will be short, and the experiment made therefore in a comparatively short time.

If, however, an expression of the form

$$f(v) = 10^{a - bv}$$

can be regarded as representing with sufficient accuracy the law of life for all types of incandescent lamps, then if sufficient experiments be made with a number of lamps at each of two different potential differences, to enable us to determine the average life at each of these potential differences, the constant a and b can be calculated from the equation, and hence the value of $f(v)$, the life, calculated for any other potential difference.

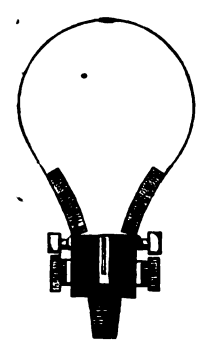
In connection with this investigation we have endeavoured, with the aid of one of our assistants, Mr. Walmsley, to ascertain whether some form of ordinary cheap candles can be used, at any rate for rough photometric measurements, in place of the much dearer standard candles, and as far as the following results obtained with seven candles, selected at random from a packet of No. 8 sperm candles, go, it would seem that these candles do not differ so very much more in intensity from one another than standard candles are said to do. Further experiments, however, on the matter must of course be made before a decision can be arrived at; but, in the meantime, the following results may be interesting. This particular type of candle (No. 8 sperm), costing 11d. per lb., was selected because such candles resembled in thickness the standard candles which we have been accustomed to use, and which cost 2s. 9d. per lb.

	Grammes for wax burnt per hour.	Light on terms of that emitted by the standard candle.
Standard candle.....	7·82	1·00
1st sperm candle	Doubtful	1·14 (?)
2nd „ „	6·102	1·00
3rd „ „	7·188	1·00
4th „ „	7·29	1·02
5th „ „	7·1	1·02
6th „ „	6·84	1·05
7th „ „	6·66	0·99

These tests of candle power were not made with any very high degree of accuracy, but the comparison of these No. 8 sperm candles with the standard was carried out with probably quite as much accuracy as is employed in making ordinary commercial experiments on the luminosity of incandescent lamps.

THE COX-WALKER LAMP HOLDER.

The new holder for incandescent lamps, which forms the subject of our illustration, has already been described in the pages of *The Electrician*. It consists of a block of insulating



material, three quarters of an inch square, with a deep groove across the middle, in which two metallic nipping plates (which would be better if they were lined with platinum), acted upon by two clamping screws, are fixed. These receive the loops of the lamp, and are connected to the upper terminal screws shown in the illustration. To insert the lamp it is only necessary to put the point of the glass bulb in the small loop at the bottom of the brass wire, place the connecting loops of the lamp between the nipping plates of the holder, and to screw up the clamps so as to ensure good electrical contact, an operation which would not occupy ten seconds.

We venture to suggest that the line of shadow cast by the brass wire loop encircling the lamp will detract somewhat from its usefulness; in other respects the holder is to be highly commended.

PRIMERS OF ELECTRICITY.—These Primers, which had a large sale at the recent Philadelphia Exhibition, can now be obtained at the office of *The Electrician*, price 1s.

CONDENSERS.

We invite those of our readers who are Electricians and who have Condensers in their charge to kindly furnish us with information as to the actual capacity of such Condensers as against the nominal value; together with a note of the temperature readings with both wet and dry bulbs; and any other data which may be of interest.

ELECTRICITY FOR WORKING RAILWAY SIGNALS AND POINTS.

It was with great surprise we read the announcement three or four weeks ago that a somewhat hackneyed subject was to be discussed before the Society of Telegraph Engineers. We had printed in our columns as long ago as last March (*The Electrician*, March 22nd, 1884) a full description of Mr. Currie's appliances for working signals and points on railways by means of his long-pull magnets, with ample illustrations; and later in the year (November 8th) we reprinted a paper delivered by Mr. Timmis before the Institute of Mechanical Engineers, dealing more in detail with the electrical and mechanical merits of the same invention. Since then it appears to have been re-delivered in the provinces; and now, lastly, it finds its way to the place where, one would have thought, it should have made its appearance first. The paper read before this Society is almost word for word identical with that printed by us in November. So far as these circumstances imply that, on the one hand, Mr. Timmis maintains an undisturbed faith in the value of the subject he has so energetically taken up; and on the other that the Council of Telegraph Engineers and Electricians think it a good thing, and that we cannot have too much of it, the inventor and promoter have reason to congratulate themselves; though the paucity of subjects for discussion which this incident seems to betoken is not a matter on which we can congratulate the Society.

Nevertheless, the acceptance of the paper was amply justified by the lively interest it awakened, and the prolonged discussion it evoked during the whole of the next following meeting; and that the subject is one of vast importance is of course unquestionable. If electro-magnetism can be safely employed to supersede the present system of hand-pulled signals and points, it is obvious that a great boon would be conferred on railway management, and a great addition made to the safety of railway travelling—to say nothing of the railway servants, whose duties in attending to points and signals are often attended with the greatest jeopardy to life and limb.

Electricity has long performed most valuable functions in ministering to the block system, and in generally informing the signalmen of the whereabouts of the traffic. But up till now the only means of communicating, so to speak, with the men in charge of the trains has been by hand-pulled semaphores, which can only be worked for a limited distance because of mechanical difficulties inseparable from the use of such appliances. In the case of points the operation is even more limited and risky. Moreover, the direction and angles in which the lever pulls can be exerted with effect are confined within narrow limits, necessitating as a general rule a congestion of traffic in close proximity to the signal-box, in order to bring the lines and signals within the area commanded by the mechanical operations of the signalmen. If the distances could be extended there would be a corresponding saving of signal-boxes and men, as well as a manifest advantage to the guards and engine-drivers. And if the signalling were independent of direction, curve, or angle there might be greater economy in laying down the permanent way.

That these obvious considerations have hitherto not resulted in a further application of electricity to such requirements is due probably to the repeated failure of attempts to obtain powerful electro-magnets except with an expenditure of enormous battery power or to get a long pull with any sort of uniformity of action or with an action capable of being controlled. Mr. Currie has certainly made a valuable addition to the mechanical capacity of electro-magnetism by the invention now under consideration. A reference to the descriptions and illustrations in our pages above-mentioned will sufficiently explain its principle. In combination with a counterweight acting at a suitably-varying leverage an approximately equal pull—we quote Mr. Timmis's words—is obtained through a considerable range, and violence of contact in the closing of the disc upon the magnet is avoided. By suitably adjusting the several proportions of the various parts the pull can be so greatly varied both in force and range that it can be adapted to meet almost any requirements. By a further adaptation of the same principle, placing two single magnets in combination endwise, control over three positions is obtained; and the inventor claims this as a useful application for signal arms that are required to stand at the three positions of danger, caution, and line clear. The magnetic attraction is said to be more evenly distributed, over a longer range, while the initial pull is stronger and acts at a greater distance than in any other electro-magnet of the same weight and with the same current.

The electrical criticisms offered during the discussion before the Society of Telegraph Engineers may be described as either merciful or friendly, according as one may estimate the practical value of the invention. Some mistrust was shown as to the figures adduced relating to the cost of maintaining the

Digitized by Google

signals in working order. The result of calculations on theoretical bases were a little too fanciful for the credulity of the audience; and when next we hear of Mr. Timmis's paper we hope to learn what the railway people say on the subject, if indeed the experiments at Swansea are not quite gratuitous. One or two electrical engineers connected with railway signalling were dubious about the safety of a system dependent, it would seem, on electrical connections and combinations somewhat delicate and complicated; whilst others thought that the expense would be too great—whether the initial expense or the cost of maintenance was not made quite clear. But those who had seen the appliances on view expressed themselves highly gratified with the system; and as to its practical working there is the important fact that it has been in use on a line of railway at Swansea for several months without the occurrence of a single hitch or accident of any kind whatsoever.

One objection to the system is that it involves, or, at all events, is most efficient with, the use of secondary batteries, which is obviously not an economical, nor, except near large central establishments, a practical source of power. We take leave also to demur to the suggestion that the same batteries may be used to maintain the lights in the signal lamps and at the points. Impracticable suggestions such as these rather tend to arouse misgivings as to the soundness of the main scheme. But promoters would probably not be promoters if they did not possess a lively fancy. Whatever its merits, however—and it has many—Mr. Currie's invention will not suffer for want of being well trumpeted; and we are glad of it. If the possibility of working railway signals and points by electromagnetism be demonstrated by Mr. Timmis's indomitable perseverance, we may hope to see, if not this, some better system sooner or later meet with general acceptance.

CORRESPONDENCE.

ELECTRO-MAGNETS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: "Volt-Ampere" is rather hard on me. When I give him shortly the result of two or three years' past work, he grumbles because I do not give also a year or two's work which has yet to be done. But I will do my best. I will answer his last question first. (I assume that u is a misprint for μ).

"Consequently $\frac{l}{\mu}$, as the first term of ρ, does not seem to get that alteration we are accustomed (with short magnets as regards their diameters) to see."

I believe this is incorrect. My observations on bars show that between such limits as $\mathfrak{B} = 2{,}000$ and $\mathfrak{B} = 15{,}000$ the magnetic resistance ρ is practically constant—*i.e.*, the magnetism is nearly proportional to the excitation. This is even more true for short bars than long ones. For very short bars the resistance of the metal forms so small a part of that of the whole circuit that the whole resistance is nearly independent of the permeability of the metal. The fact is generally admitted.

As to the magnet core 5½in. long and 2½in. diameter, I think the formula would not be quite correct for this; but the resistance would be greater than that given by the formula. I have computed roughly from such data as I have how many ampere turns it would take to raise $\mathfrak{B}$ in the equatorial section of such a magnet to such a value as 18,000, and I find a very large number, something like 20,000 ampere turns. I find it difficult to understand how a cylindrical core, without pole pieces, as described, can be saturated by 5,000 or 6,000 ampere turns; for my Gramme cores are not so far from the same dimensions, and have pole pieces which reduce the shape resistance to almost nothing compared to the resistance of the cylinder, and they take fully 5,000 ampere turns when the machine is in full work. And I have other reasons. I think there must be some mistake. Are there not pole pieces? How was the amount of saturation ascertained? And how were the ampere turns measured?—Yours, &c., R. H. M. BOSANQUET.

St. John's College, Oxford, 1st March, 1885.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I write in the interests of numbers of people situated like myself, never knowing from day to day what lamps are coming next.

I have altered the lampholders here about four times for 200 lamps, and twice for another 200 lamps, and yet the end has not come! I was delighted to use the Swan socket lamps, but unfortunately they were so badly made that some fitted and others would not, the result being that many broke in the hand. Then came the pretty vitrite fittings; but here every third lamp broke off at the vitrite pins, and were rendered useless. Many also had bad contacts between the platinum wires and the cap. Out of every 25 lamps about eight have gone wrong in this way. The loops seem the best so far; and notwithstanding all that has been said against the side loops of the high resistance lamps they have many advantages, because the spring is not outside the hooks in the holder, and short-circuiting is almost impossible. I would suggest that lamps should be made like the side loop lamps, only with a straight pull, as in the present make; and for the vitrite bottom lamps better contacts should be made, and pins of metal cast in the vitrite for fitting in the bayonet joint.—Yours, &c., DAVID SALOMONS.

Broomhill, Tunbridge Wells, 3rd March, 1885.

[On looking again at the specimen of vitrite fittings forwarded to us, we find it broken as described by Sir David Salomons. A second specimen we have seen has likewise gone. This seems to point to careless manufacture, as the material itself looks sound and good.—ED. *E.*]

NEW UNITS FOR OLD ONES; COST, £(?)0,000.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It seems hardly to be realised by the electrical world that our standards of measurement are getting into a state of hopeless confusion. This is perhaps partly because the error of the B.A. units is looked upon as very small, whereas it is really large enough to cause, for instance, perceptible errors in running glow lamps. The electrical engineer may readily realise the value of 1·3 per cent. by imagining his income tax raised threepence, if he has an income. And it is partly, perhaps, because these matters are settled by men of such calibre that we are naturally inclined to accept their recommendations gratefully and without question. But it may be as well sometimes to throw off the respect due to such men as the members of the Electrical Congress, and to look at their doings without pink spectacles.

At present there are no less than three different values of the volt and ohm in use. First, there are the B.A. volt and ohm, or 1864 units, which are now in almost universal use. Then there are the ohm and volt according to Lord Rayleigh's determination, and now there are the "legal" ohm and volt, so-called because they are not legal, which were got by taking the mean of a lot of determinations without respect to the probable accuracy of each, and wiping off a decimal for no obvious reason. The accurate determination of the ohm is a matter of very great scientific interest; but is it at all reasonable to change our practical and commercial ohm and volt because they are wrong for others also wrong? Though much nearer the theoretical units than were the B.A. units of 1864, even the Rayleigh volt and ohm must in the nature of things be wrong, and the ohm must eventually be the resistance of one particular piece of wire, and that particular resistance cannot be made exactly correct, though the error may have only a scientific, and not commercial, consequence like the present error.

What are the advantages of changing our ohm and volt? First, our units, as multiples of the C.-G.-S. units by powers

Digitized by Google

of ten, will be correct. This is not quite true; they will only be somewhere about right, the error being periodically varied by congresses, and the temperature labels for resistance boxes being published like Stock Exchange quotations. This accuracy seems to be considered of great importance by some, but is a matter of no practical importance. Then the alteration will make 746 watts equal to one horse-power. But it is just as easy to use 755, or, perhaps better, 756 as a coefficient. Another advantage would be that when mechanical engineers measure power in watts, their watt will agree with the electrical watt. But is there the remotest chance of mechanical engineers adopting the C.-G.-S. units? If they give up measuring work in foot-pounds they will measure it probably in kilogrammetres, not in joules or ergs multiplied by other powers of ten. From a sentimental point of view the kilogrammetre is in one way more consistent than the C.-G.-S. unit; for though the gramme may now be defined as the mass to which unit force gives unit acceleration, it was the weight of a C.-C. of water, so that while the kilogrammetre involves gravity and not acceleration, the erg and joule involve both. The watt and joule are themselves inconveniently small for engineers. If they ever take up the kilogrammetre, their units will be only ·7 per cent. out as round multiples of the B.A. units, so that a coefficient need only be used for exact work; but if the ohm be made approximately correct they will be nearly 2 per cent. out, ·981 being the coefficient. But if their standards were to be at the mercy of international congresses, who may alter them and make them somewhere about right at any odd time, they will probably stick to their horse-power, foot-pound, B.W.G., and their cherished nominal horse-power till doomsday.

What are the disadvantages of the new units? First, endless confusion. Even now, though the B.A. units are 20 years old, we still come across Siemens units. More than this, the average writer on electrolysis tells you he gets this effect or that by "passing the current of ten Smee cells;" and the average French chemist uses the old notation, and measures his E.M.F. not even in Daniells, but in calories. How long, then, must it take before the confusion due to three pairs of units with the same names disappear? The question really resolves itself into, what are we to do about our resistance boxes? We cannot use coefficients. Instruments in common use must be direct reading, and must involve no calculations, whatever may be permissible in the laboratory. It would generally be cheaper to put a bridge box aside and get a new one than to use a coefficient. The bridge box might be altered by altering one side of the bridge itself in the proportion of 1 : 0·9886; but at the best that would be patchwork.* When the number of boxes in use is remembered, it is evident the mere cost of alterations will cost us many thousands of pounds. Is it worth while paying this merely to be able to say, "Our ohm is somewhere about right, for exact error see latest determination of the ohm?" The potential galvanometers now in use do not matter much, they are mostly wrong "anyhow." Then, again, every time a resistance box or anything else accurately measured is wanted, the seller will have to ask, like a bank clerk "How will you have it?" Unfortunately, members of the congress are not the people who have to make resistance boxes, and cannot even be said to use instruments commercially, or out of the laboratory. When a congress resolves on a S. C. of melting platinum as unit of light, the men who use light standards daily treat it, as Mr. Ward says, with "skorn," and go and buy a Referee burner from Mr. Sugg, and either calibrate their standard glow-lamp from it, or use it itself with proper precautions. It is a popular delusion that glow-lamps are always tested against standard candles. If a practical standard is derived from the Violle standard, and left so that copies may be made, of course no confusion arises; but if a new standard is made, nearly a candle-power, and called a candle, there will be more trouble. Perhaps, in settling standards of light an insignificant industry called the gas trade may be considered. Any one who knows anything of the gas trade may imagine how eagerly a standard of light derived from a S. C. of melting platinum will be snapped up and put into universal use, especially if there is a chance of a new determination of the candle every now and again.

Of course, it must be remembered that if the Rayleigh, or even the "legal" ohm, be adopted, whenever a congress decides on a new value it will be so close that the temperature labels only of resistance boxes will have to be altered. But while writing as a Philistine, and before replacing the pink spectacles, a suggestion occurs. Why should not the International Congress have their resistance boxes made in "legal" ohms, but use them at such a low temperature that they fit the B.A. ohm? If they hire Mr. Cook or Mr. Virgil to conduct them personally to the district Dante describes as so very, very cool, and use their resistance boxes there, would any one complain of the new change?—Yours, &c.,

March 4, 1885. JAS. SWINBURNE.

[Mr. Swinburne is only urging what we have maintained long ago, and we venture to hope that many practical men will support these views.—ED. *E.*]

* A bridge box to compensate for temperature might be made by using different metals in the bridge. Thus platinum silver coils, and platinum silver on the line side of the bridge, with gold silver alloy on the other side of the bridge, might be nearly compensating.

PERSONAL SAFETY AND ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I beg to offer my best thanks to Mr. Trotter for the information he has so kindly furnished with reference to the fatal accident at The Healtheries. I should be glad if the physiological actions could be traced.

Does the violent contractions of the muscles of the chest cause a stoppage of the flow of venous blood to the heart, and does death thereby ensue, or is the effect similar to that of strangulation?

Another point on which we should also be clear is—did 1,200 volts, applied to the hands of a healthy man, kill him; or did he receive a higher E.M.F., due to an *extra* current?

Evidently the destructive properties of any machine may be materially modified, as M. D'Arsonval has shown, by the winding.

A dynamo whose E.M.F. was produced by very large magnets, with comparatively few turns of wire, would be less dangerous than one having the same E.M.F, produced by smaller magnets, a smaller current, and a larger number of turns of wire round the magnets.

Hoping that the physiological question will be attacked by some of those gentlemen who are conversant with the subject, and who have the time.—Yours, &c.,

SYDNEY F. WALKER.

195, Severn-road, Cardiff, 4th March, 1885.

THE SKRIVANOV BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I shall feel greatly obliged if any of your readers can give me particulars of the Skrivanov battery, and how to construct it, its power and duration of useful work. Are the used-up materials reconvertible?—Yours, &c., W. FORBES.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

The discussion on Mr. J. A. TIMMIS'S paper relating to the "Working of Railway Signals and Points by Electro-magnets," read on the 12th February, took place at the Society's meeting on Thursday, February 26th, Mr. Spagnoletti, president, in the chair. Mr. LANKESTER opened the discussion by stating that from the engineering point of view Mr. Currie's invention—described by Mr. Timmis—appeared to answer its purpose admirably for dispensing with long and heavy levers. He could offer no opinion, however, on its electrical merits, as he was not an electrician. Mr. LANGDON, while expressing a general approval of the long-pull magnet for distant signals, thought that its application to the general system of block signalling was of doubtful utility. Speaking as an electrician, he feared that the electrical arrangements were complicated, and would require constant supervision. He also thought the system would not recommend itself to the railway companies for its economy. Professor HUGHES described the various devices adopted during the past 20 or 30 years for obtaining long-pull electro-magnets, and the uses to which

Digitized by Google

some of them had been put, especially on French railways. Illustrating these diagramatically, Professor Hughes also drew attention to the method adopted by himself of using a supplementary permanent magnet under the electro-magnet for obtaining a powerful blow to release the detent in the Hughes' type printing instrument with the aid of only a very feeble current. Turning to Mr. Currie's invention, he could see on theoretical grounds that great care had been bestowed in arriving at the best form of electro-magnet for the object intended. Sir CHARLES BRIGHT also described some examples of long-pull magnets which had come under his notice. Mr. A. J. ADAMS, who thought the employment of electrical batteries uncertain and dangerous, suggested the utilisation of water, available at most stations, for obtaining hydraulic power with which to work the signals. After some remarks from Mr. CONRAD COOKE, Mr. W. H. PREECE expressed a decided opinion that Mr. Currie's system would be admirably adapted for long-distance signal working, but doubted the advantage of employing it for near signalling, which could be quite as well done by hand. He had thoroughly examined the apparatus on the inventor's premises, and had greatly admired it. He had also heard a good report of it from Swansea, where it has been at work now for several months. Professor AYRTON thought there was a needless expenditure of force in working the long-pull magnet solely with the view of instantaneously raising the signal arm, whereas the arm could be raised gradually, but quickly, by means of a motor with far less expenditure of electrical power—a method of working railway signals which Professor Perry and he had already given some attention to. At this point in the discussion, a long communication from Mr. S. F. Walker was read, criticising Mr. Timmis's conclusions, but referring chiefly to things that had been said at a meeting held at Nottingham. Some other gentlemen, whose names did not transpire, pointed out that the Board of Trade's regulation forbidding the employment of signals at distances further than 150 yards was inconvenient and expensive. Mr. Currie's invention, if practicable and safe, would have the effect of extending this limitation; and Mr. CURRIE, the inventor, as well as Mr. Timmis, both of whom replied to criticisms, stated that the Board of Trade would only be too glad to extend the distance providing it could be done with safety. Mr. Currie's system would probably be the means of dispensing with a number of signal boxes, at every one of which three men had to be employed; and it had this great advantage, that it gave three positions even at long distances, which no hand-worked signalling could do. The congestion of rails now necessitated by the existing hand-pulled signalling would also be done away with by working the signals electrically, as the current would travel in any direction or at any angles you pleased.

The usual vote of thanks concluded the discussion, which, having been unusually prolonged, Sir DAVID SALOMONS' promised paper, "On Constant Electromotive Force in an Electric Light Circuit," was postponed till the next meeting.

ON THE SEAT OF THE ELECTROMOTIVE FORCES IN THE VOLTAIC CELL.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

TABLE OF CONTENTS.

Chapter I. *Historical and Critical.*

1. Short historical sketch of the views and methods of the early period.
2. Commencement of the modern period.
3. Summary of the work done by the more modern experimenters—Hankel, Ayrton and Perry, Clifton, Pellat.
4. Experimental inquiry into, and general discussion of, the effect of atmosphere on Volta effects—Pfaff, De la Rive, Brown, Thomson, Pellat, Schulze-Berge, Von Zahn.
5. Views of Exner. Papers of Knott and Hart.
6. Account of other papers bearing on the subject; and views of Faraday.

1. The subject chosen for the present discussion illustrates in a remarkable way the need for such conversations. It is scarcely credible, at the present rate of progress, that eighty-four years after the discovery of the voltaic pile, opinion should still be utterly divided as to the seat of the main E.M.F. in it. I venture to hope that it may now be decided, and a substantial agreement arrived at with respect to it. My business is to open the discussion; but it so happens that for some seven or eight years I have believed myself to see more or less clearly to the root of this particular matter, and a laborious review of the literature of the subject has only strengthened my conviction. Having, therefore, strong and definite views I can hardly help letting them appear; and without assuming prematurely that these views are agreed with, they may yet serve as a link with which to connect the facts and the multifarious observations thereon.

In the course of my reading on the subject I have found only two great and epoch-making papers, that of Volta in 1801, and that of Sir William Thomson in 1851. The other contributions are some of them keen, like those of Faraday and Clerk Maxwell; some of them laborious, like those of Hankel and Ayrton and Perry; but none contain anything essentially and powerfully new except those two: unless, indeed, we include in the subject the immensely important phenomena of Seebeck and of Peltier, and Faraday's fundamental law of electro-chemical decomposition.

Volta* showed that when two metals were put into contact and separated, the insulated one was charged with electricity sufficient to make gold leaves diverge. He also stated that the contact force between any two metals was independent of intermediate metals, so that the metals could be arranged in a definite numerical series; and he gave the first series of the kind :—

Zn	Pb	Sn	Fe	Cu	Ag.
5	1	1	2	3	

Moreover, he started a hypothesis to account for the action, a sort of impulsion or attraction of electricity by matter—an idea subsequently elaborated by Helmholtz. Fabroni† objected to Volta's explanation of his experiment. He denied contact force, and considered that the electricity was developed by chemical action.

Then the fight began, and lasted on and off some half century. On the one side were Volta, Davy, Pfaff, Péclet, Marianini, Buff, Fechner, Zamboni, Matteucci, and Kohlrausch. On the other were Fabroni, Wollaston, Parrot, Œrsted, Ritchie, Pouillet, Schönbein, Becquerel, De la Rive, and Faraday.

It was not all fighting; part of it resulted in a more thorough investigation of voltaic phenomena; and very often the original point of dispute was lost sight of, and Volta's fact itself was doubted in the eagerness to disprove Volta's explanation. The experiments of Pfaff and Péclet‡, however, fairly well established the correctness of his observation; and Kohlrausch showed how, by means of a Daniell's cell combined with a condenser, to measure Volta forces absolutely, thus inventing a method which has been employed with modifications by Hankel, by Gerland, by Clifton, by Ayrton and Perry, by Von Zahn, and by most other experimenters on the subject.§

Wherever electrostatic methods were employed, and where the electroscope was the instrument of research, contact theorists had it all their own way; and it was only by apparent effort and twisting of experiments that chemical theorists could maintain their ground. But when electric currents were dealt with, and the galvanometer used, then the chemists had their turn, and they showed most conclusively that no mere contact could maintain a current unless heat disappeared or chemical action occurred: a fact obvious enough to us to-day on the principles so laboriously and finally established by Joule. By means of the galvanometer, the contact theory was so belaboured by Faraday that it ultimately seemed to give up the ghost, and the chemical doctrines triumphed. So much so, that Volta's original fact, in spite of the evidence which had been

---

* Professor O. J. Lodge contributes the first of five chapters on this subject to the current number of the *Philosophical Magazine*, with the following letter :—"The accompanying tract is an expansion of a paper drawn up as the opening of a discussion on Contact Electricity by Section A of the British Association at the Montreal meeting. It is in five portions or chapters. The first of these [printed this month] is mainly historical; in the second and third portions theoretical views are considered, and my own are given at some length in accordance with the kind advice of Sir W. Thomson; the two remaining chapters are occupied with cognate thermo-electric phenomena, with the theory of the simple voltaic cell, which singularly enough is pretty complicated and very little understood, and with a discussion on the size of atoms. Although the paper is being printed in the annual volume of the Association, it has been suggested that a further publication of it might be useful in order that physicists may have a better and more leisurely opportunity of contributing to the discussion of a matter which must have occupied the attention of every one more or less, which branches out into several interesting and important developments, and which, as a matter of controversy, has remained singularly long unsettled. I will therefore ask you to find room for it in your journal, in the hope that the discussion may be there conveniently continued and properly closed."

Pfaff, Letter to Gay Lussac: *Ann. de Chim.* 2 ser. xli. p. 236 (1829).—Plaff: For and against the production of Electricity by Chemical Processes, as a consequence of some experiments on the E.M.F. of liquids and metals: Pogg. *Ann.* xli. 1840, pp. 110 and 197.—Pfaff: Experimentum crucis in favour of the Contact Theory: Pogg. *Ann.* liii. 1841, p. 303. This crux is on p. 306, and consists in substituting $ZnSO_4$ for H_2SO_4 in a Grove cell, and showing that the current through a thin wire galvanometer is stronger than before. This, he says, leaves no further shift or evasion (Ausflucht) for the chemical theory. It is a fact we have grown accustomed to, but it *is* rather surprising, that the E.M.F. given by $ZnSO_4$ should be even higher than that given by H_2SO_4. A convenient "Ausflucht" could nevertheless be provided for the chemical theory by pointing out that the combustion heat Zn, $2NO_3$ is greater than Zn, $SO_4 - H_2SO_4 + 2(H, NO_3)$, if indeed the fact be so. Another shift is to talk about basic sulphate and the sourness of $ZnSO_4$; another is to use the word "dissociation."

§ Kohlrausch's method consisted in bringing the plates of the two metals close together, connecting them by a wire for an instant, separating them, and putting one into connection with a Dellman electrometer, the other with the earth. The observation is repeated with a Daniell in the connecting wire, first one way, then the other. Thus three equations are obtained,

$$M/M' = k\alpha,\quad D + M/M' = k\beta,\quad D - M/M' = k\gamma\ ;$$

whence

$$M/M' = \frac{B-\gamma}{B+\gamma}D,\ \text{or}\ \frac{\alpha}{\beta-\alpha}D.$$

(Pogg. *Ann.* vols. lxxv. p. 88, lxxxii. pp. 1 and 40, and lxxxviii. p. 465, 1851 and 1853). He gets his results much lower than later experimenters; only ½ a volt for Zn/Cu, and ·58 for Zn/Pt.

Digitized by Google

accumulated, was again doubted; and one finds in text-books culled from this period statements that Volta must have had wet fingers, or that he rubbed the plates together, or that there was moisture in the air. Also hints are given that films existed on the plate, that squeezed coats of varnish or lacquer might produce some electricity, and so on. It was pointed out, moreover, by De la Rive*, how minute a trace of chemical action could produce how much electricity, and how little electricity could affect an electroscope. But it is to be noted than any chemical action caused by damp on the plates, or moisture in the air, would be of the nature of local action, and local action is not a satisfactory producer of manageable electricity. Sir Humphry Davy is very clear on this head. He shows that chemical action need produce no electricity, instancing the burning of iron nitre on charcoal, potash and acid in a crucible or an electroscope, &c.; a plate of zinc placed on mercury and separated is found positive, but if left long enough to amalgamate, the compound shows no signs of electricity. Davy's views are singularly advanced, and are worth quoting.†

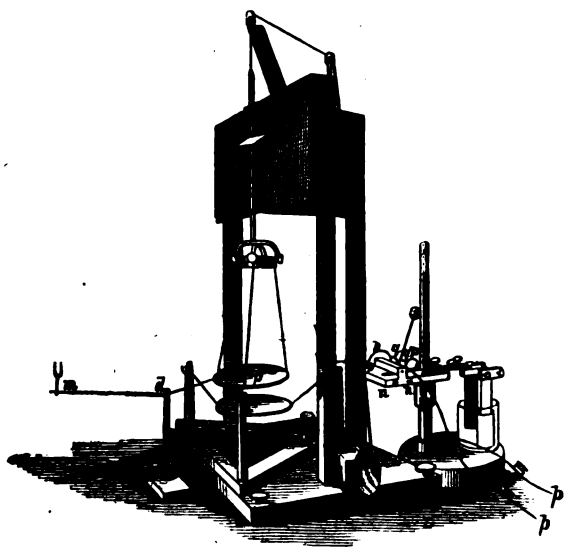

FIG. 1.—Kohlrausch's Early Form of Condenser.

Both the plates are insulated by silk threads. The fixed wire, *d*, with which the raised plate comes into contact, leads to a Dellman electrometer. The connections are arranged for determining the "electroscopic tension" on the poles of an open battery, to see if it is the same as the E.M.F. (See Pogg. *Ann.* 1848, vol. lxxv. pp. 88 and 220.)

This apparatus he also used to measure the Volta effect between two metals, his classical memoir on the subject being in Poggendorff's *Annalen*, 1851, vol. lxxxii. p. 1. Later he improved the condenser, bringing it into the form shown in the following figure.

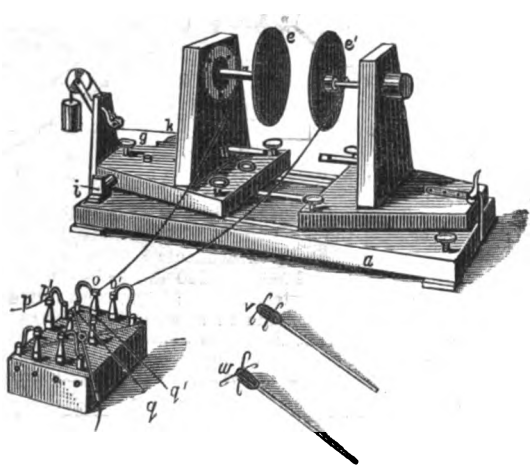

FIG. 2.—Kohlrausch's Later Form of Condenser.
(See Pogg. *Ann.* 1853, vol. lxxxviii. p. 464.)

Quite detached from any connection with the controversy, because at that time quite unintellibible to all but one or two here and there, two papers appeared in 1851 by the President of this Section, which were the triumph and apotheosis of the chemical theory of the source of the current in the voltaic cell.* In one of these papers (that on "Electrolysis") it is irrefutably established, on the basis of the conservation of energy, that, making exception of such irreversible effects as are not readily brought into calculation, and allowing for certain possible reversible effects to be investigated thermo-electrically, the E.M.F. of a cell is not only dependent on the chemical action going on, but is calculable numerically in absolute measure on purely chemical data supplied provisionally by Dr. Andrews. It is proper to say, however, that this brilliant theory is avowedly based on the laborious and acute experimental work of Joule on the conservation of energy in the voltaic circuit†.

In the other of the two papers (that on "Thermo-electricity") it was shown that, from the fact that a current absorbed or generated heat at a metallic junction, an E.M.F. was necessarily situated there—in other words, that the Peltier effect necessitated the previously-discovered Seebeck one.

The establishment of the conservation of energy, by Joule, for ever placed beyond doubt the fact that the energy of the electric current produced by a battery was due to, and was the equivalent of, the chemical actions going on there; but it was supposed, and is still supposed (though, as I venture to think, quite erroneously), to leave untouched the question as to the precise seat of the E.M.F. in a battery.

However that may be, the success of the chemical theory of the electric current naturally caused it to be still more certainly assumed that the apparent contact force of Volta could also be accounted for by accidental chemical action, and that without some chemical action somewhere no Volta effect could be produced. This, also, I believe to be quite false; provided always that the phrase "chemical action" be used in its ordinary sense as meaning combination, and that the word "action" be not explained away as meaning anything whatever.

2. The triumph of the chemical theorists with regard to the Volta effect was, however, shortlived, for, from 1860, the invention of the quadrant electrometer put into the hands of electrostatic experimenters a far more refined and delicate instrument than could have been thought possible a few years before; and the illustrious inventor of that instru-

* De la Rive: *Traité d'électricité*, ii. p. 776; *Annales de Chimie*, xxxix. p. 311 (1828).

† Davy, Bakerian Lecture, 1806 (see Phil. Trans. 1807, p. 39. :—"As the chemical attraction between two bodies seems to be destroyed by giving one of them an electrical state different from that which it naturally possesses. . . . . so it may be increased by exalting its natural energy. Thus, while zinc is incapable of combining with oxygen when negatively electrified in the circuit even by a feeble power, silver easily unites to it when positively electrified. . . . . Among the substances that combine chemically, all those, the electrical energies of which are well known, exhibit opposite electrical states. . . . . In the present state of our knowledge it would be useless to attempt to speculate on the remote cause of the electrical energy, or the reason why different bodies after being brought into contact should be found differently electrified; its relation to chemical affinity is, however, sufficiently evident. May it not be identical with it, and an essential property of matter?"—Page 44: "The great tendency of the attraction of the different chemical agents by the positive and negative surfaces in the Voltaic apparatus seems to be to restore the electrical equilibrium. . . . The electrical energies of the metals with regard to each other or the substance dissolved in the water, seems to be the cause that disturbs the equilibrium, and the chemical changes the cause that tends to restore the equilibrium; and the phenomena most probably depend on their joint agency." He then gives a very Voltaic account of the action of the pile—much in agreement with Sir Wm. Thomson; and endeavours to reconcile chemical and contact theorists by pointing out how essential a part chemical action plays in the production of a *current*, a most clear-sighted thing to do at that date. One more sentence may be quoted from this remarkable paper, though it is not quite so striking as the preceding. —Page 49: "These ideas are evidently directly in contradiction to the opinions advanced by Fabroni, and which in the early state of the investigation appeared extremely probable—viz., that chemical changes are the *primary* cause of the phenomena of Galvanism. Before the experiments of M. Volta on the electricity excited by mere contact of metals were published, I had to a certain extent adopted this opinion; but the new fact immediately proved that another power must necessarily be concerned, for it was not possible to refer the electricity exhibited by the opposition of metallic surfaces to any chemical alterations, particularly as the effect is more distinct in a dry atmosphere, in which even the most oxidizable metals do not change, than in a moist one, in which many metals undergo oxidation."

* Sir W. Thomson:—1. "On the Mechanical Theory of Electrolysis and the Applications of the Principle of Mechanical Effect to the Measurement of Electromotive Forces in Absolute Units," Phil. Mag., December, 1858. Reprint of Mathematical and Physical Papers, vol. i., pp. 472 and 490. 2. "On the Dynamical Theory of Heat, part vi. Thermoelectric Currents:" Proc. R. S. Edin. Dec. 1851; Trans. R. S. Edin. 1854; Math. and Phys. Papers, vol. i., pp. 232 and 316.

Helmholtz also clearly applied the conservation of energy to voltaic circuits in his memoir *Die Erhaltung der Kraft*. read before the Physical Society of Berlin, 23rd July, 1847. In this powerful memoir Professor Helmholtz sails placidly through a great part of physics, applying to various phenomena the then new principle of the conservation of energy. He regards all action as occurring at a distance, and shows, as is well known, that, on this hypothesis, central forces are the necessary and sufficient condition of conserved energy. This part may now be regarded as superseded; but in the more special portions, among other things, he develops the mechanical theory of the E.M.F. of voltaic cells, of thermo-electric piles, and of magneto-machines, anticipating in many respects the somewhat later though independent work of Sir W. Thomson on these subjects.

Prof. Helmholtz's memoir is easily accessible through a translation, by J[ohn] T[yndall], which appeared, in May, 1853, in the "new series" of 'Scientific Memoirs,' issued by Taylor and Francis.

Digitized by Google

ment himself for ever put the truth of Volta's phenomenon beyond doubt, by the most simple and beautiful device of suspending a charged torsion arm over a zinc-copper junction. By comparing the deflection so produced with that caused by a Daniell cell, an absolute measure of the so-called contact force was made; and it was shown that, uniting the copper and zinc by a drop of water, instead of by a metal, no deflection was produced. It was also shown that the deflection was greatest when the zinc was clean and the copper oxidised.*

But Sir William Thomson went further than this: he sounded a theoretic note, and in a sentence revived the whole controversy about the seat of power in the pile. The sentence is this:—"For nearly two years I have felt quite sure that the proper explanation of voltaic action in the common voltaic arrangement is something very near Volta's, which fell into discredit because Volta or his followers neglected the principle of the conservation of force. I now think it quite certain that two metals dipped into one electrolytic liquid will (when polarisation is done away with) be at the same potential." And then he goes on to one of those brilliant and extraordinary speculations characteristics of no one else, and applies this apparent contact force to determine a lower limit to the size of atoms—an application obviously of transcendent interest, and of more importance than all the previous outcome of contact discussions put together.†

The whole subject now acquired a fresh interest, and the new series of experimental determinations of contact force began.

3. Hankel's and Gerland's measurements belong to this period in point of date (1861-69), though in method and motive they probably are the outcome of the earlier period.‡ Hankel uses a modified Kohlrausch method and a Bohnenberger or Hankel electroscope; his special merit is the determination of metal-liquid contact-forces without introducing blotting paper, glass, or fingers, as the earlier experimenters had done.

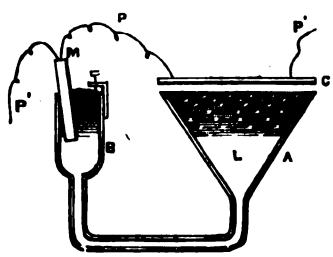

FIG 3.—Hankel's Arrangement for Observing the Volta Effect between a Metal and a Liquid.

The liquid, L, is in a funnel-tube, A, B; C is a copper plate, and M the metal under observation. First, p touches C for an instant, then C is raised and made to touch p', which leads to a Hankel electrometer.

This gives $\quad Cu/M + M/L = k\alpha.$

Then the liquid is run out of the funnel, a plate of the metal M is placed on its mouth, and the experiment repeated.

This gives $\quad Cu/M = k\beta.$

To eliminate k substitute a plate of zinc for M, and get

$$Cu/Zn = k\gamma.$$

Then, finally, $\quad M/L = \dfrac{\alpha - \beta}{\gamma} Cu/Zn.$

In all these expressions air contact-forces are, as usual, neglected. But it is very tempting to try if, by inceasing the number of such equations, one cannot calculate some metal/air contact forces. Thus the special case when M is copper gives one more equation. We can then take zinc instead of M, and can also make the condenser-plate of zinc instead of copper, and so on; but we get no forwarder, fresh unknowns appear as fast as additional equations, and some of the equations are liable to degenerate into identities.

So far back as 1824 Becquerel* attempted the investigation of metal-liquid contacts; and Buff† made some measurements in 1842, but his results are scarcely likely to be reliable considering the poor experimental resources of that date.

Professor Clifton employed Kohlrausch's method in 1877, using a Thomson electrometer and a Clark cell as standard of E.M.F. He has only published a preliminary paper,‡ in which he overlooks minutiæ such as change of contact-force by time and adventitious circumstances. When he touches on theory he agrees with Thomson. Professor Clifton has examined the Volta effects for the substances ordinarily used in batteries with great care, and has probably elicited the maximum of accuracy possible to his method. He gives the E.M.F. of numerous virgin cells in which no current has circulated.

Ayrton and Perry in 1876 devised in Japan a very ingenious but somewhat unwieldy modification of Kohlrausch's method, and with the help of students carried out a most extensive and laborious series of determinations of metal/metal, metal/liquid, and liquid/liquid contacts.§

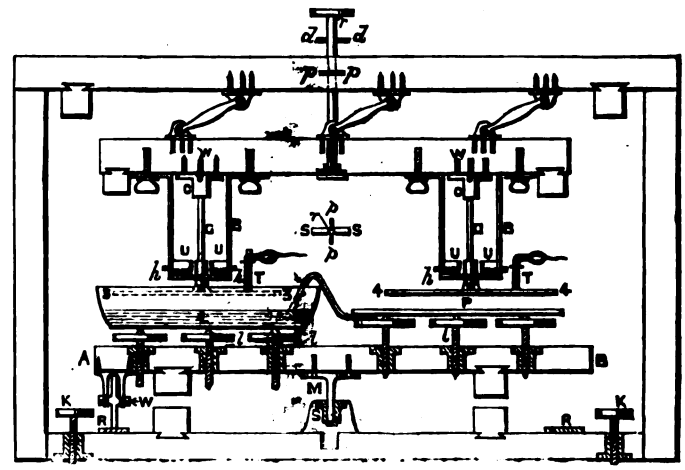

FIG. 4.—Ayrton and Perry's Apparatus for measuring the Volta effect with all sorts of substances.

The substances are arranged on the lower platform, as, for instance, the metal and liquid shown in the figure at P and L. The platform, A B, is capable of rotation through 180° on its railway, R. 3 and 4 are carefully insulated gilt plates fixed to a bar which can be raised and lowered. The experiment consists in lowering these plates close to the surface to be tested, and connecting them with each other for a short time; then raise them, rotate the platform through 180°, lower again, and connect them with a quadrant electrometer.

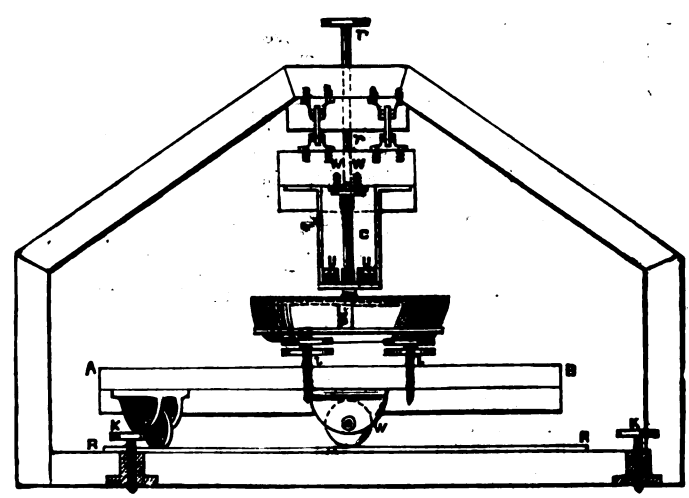

FIG. 5.—End view of Ayrton and Perry's Apparatus.

On the appearance of Clifton's paper the year after, they issued a strongly-worded claim in respect both of priority and completeness—a claim which seems to me well established, for their results are the most comprehensive yet obtained, and the energy needed to devise, construct,

Digitized by Google

and use such an apparatus as the one they depict must have been immense.* A convenient summary of their numbers is to be found in Everett's "Units," second edition. The main result achieved by them is the experimental establishment of the summation law for all substances (this is not to be confused with Volta's summation or series law, which is only applicable to metals), viz., that the total E.M.F. of a closed circuit of any number of substances may be reckoned by adding up the Volta forces observed electrostatically for every pair of substances in contact. This law is, it seems to me, for reasons given later (§. 7), very probable theoretically; but still it was quite essential to have it experimentally established, especially as Ayrton and Perry point out that it is often called in question without good ground. The establishment of this law is, I say, perhaps their main work in this matter, besides the observation of the Volta effect for various difficult substances, especially liquids and liquids.

Clifton arrives at the same conclusion with regard to summation, and gives handy diagrams, reproduced in Jenkins's "Electricity," of the contact-force at the different junctions. My own opinion is that the intended and obvious significance of these diagrams is theoretically wrong, but they embody certain experimental results conveniently, and they can be interpreted properly.

Both Clifton and Ayrton and Perry appear to believe in the great constancy of the value Zn/Cu. Clifton gives it as ·8516 volt ("Quelle précision!" somewhat sarcastically ejaculates Pellat, who himself finds it to vary between ·63 and ·92). Ayrton and Perry assert that it is more constant than a Daniell. I believe that both Professor Clifton and Professors Ayrton and Perry have made several experiments besides those recorded in their communications to the Royal Society; but as they have not been published, I can give no account of them.

Among the Thèses presented to the Faculty of Science in Paris in 1881 we find an important memoir by Pellat†, which reviews the whole position very clearly, and records a series of determinations of Volta force among metals, determinations which are evidently the most accurate and satisfactory yet made. He adopts the capital experimental method of neutralising the charge of a condenser by a Poggendorff or compensation method, and thus converts Kohlrausch's into a null method, for which a very sensitive electroscope is all that is needed. The plates of the two metals set face to face are connected, not directly, but by a greater or less length of a graduated wire conveying a current; and the position of the slider on the wire is adjusted by continually separating the plates and testing until no charge at all is found. The step of potential on the wire is then precisely equal to the "contact-force" between the plates; for this would have caused a charge in a similar but uncompensated condenser, and the step of potential on the wire has neutralised it.

(TO BE CONTINUED.)

THE DRAWBAUGH TELEPHONE CASE.

AMERICAN BELL TELEPHONE COMPANY AGAINST THE PEOPLE'S TELEPHONE COMPANY ET AL.

(CONCLUDED FROM PAGE 338.)

It remains to consider what effect is to be given to the testimony of the multitude of witnesses who have been produced to substantiate the defence.

Disregarding the testimony which is merely hearsay, and therefore incompetent as evidence of the main fact, the testimony of many other witnesses is overthrown by the palpable improbability of their statements, or by the contradictions between their statements and those of other witnesses for the defendants upon substantive points, or by successful attacks upon their accuracy in the rebutting testimony of the complainant.

There still remains a formidable number of witnesses who testify to seeing or using Drawbaugh's talking machine, and some of whom identify particular exhibits as the instruments which they saw or tried.

No doubt is entertained that Drawbaugh was experimenting at an early period with telephones or phonographs. He knew about the phonograph or phonautograph of Scott as early as in 1863. The membrane diaphragm excited by sonorous waves and the electric mechanism of the phonograph were not novelties, and, among the diversity of inventive possibilities, had probably attracted his interest. Prior to 1869 Dr. Van Der Weyde had made public experiments with the Reis telephone at the city of New York, and others had made like experiments elsewhere. In May, 1869, a full description of the instrument and of the experiments was published in the newspaper, *The Manufacturer and Builder*, treating it as a highly interesting curiosity, which contained the germ of great practical purposes. Whether other newspapers noticed the experiments or not is not shown, nor is it shown that Drawbaugh saw the article in *The Manufacturer and Builder*. It would be difficult to prove the circumstance if he did see it. Some such publication probably stimulated him to experiment. If he made a sketch of the mechanism at the start, the material for it was at hand. As is stated by Mr. Benjamin, it has been asserted of the Reis instrument that certain sounds of the human voice can be transmitted by it, but in truth these are merely fragmentary reproductions of vocal sounds, and the transmission of articulate speech could not be effected because it was constructed on the make and break principle, instead of on that of the undulatory, unbroken current.

It is not strange to any reader of the autobiography that Drawbaugh should have taken up the telephone. That he, and those about him, should have treated it as a talking machine is entirely natural. That his talking machine as late as in 1876 bore a striking resemblance to the Reis telephone is shown by Mr. Shapley's testimony, a witness who noticed the resemblance and loaned Drawbaugh a copy of the *Scientific American* describing it.

There is enough here to explain Drawbaugh's declarations to his neighbours about the talking machine he was inventing, and to excite the curiosity of the community. A careful reading of the proofs render it easy of belief that the witnesses who testify about casual visits to his shop, which occurred many years before their testimony was delivered, and to cursory tests of his instruments on those occasions, have confused the fragmentary and incoherent articulation of such an apparatus with the hearing of distinct words and sentences. When witnesses undertake (as many of them do) to give the exact word or sentence heard in the instrument five or ten years before, when their attention was not called to the subject afterwards, no hesitation is felt in rejecting such statements as utterly incredible. It may be charitably inferred that such a witness has confused his recollection with more recent impressions. As will hereafter be shown the proofs demonstrate that most of the witnesses who testify to having heard distinctly and coherently through the talking machine, all those who indicate the exhibits B, F, and C as the instruments, are mistaken if they are truthful. If Drawbaugh was a charlatan he may have assisted in deluding them, and the proofs show that between 1872 and 1874 a string telephone was in his brother's shop, in the village. The fact that he never attempted to exhibit his machine outside of his shop, where it could be used between points some considerable distance apart, and where its real capacity could be readily observed, is significant in this connection.

The more important testimony is that by which it is sought to identify the several exhibits, and show their existence at times consistent with theory of the natural evolution of the invention. The identification of particular exhibits as seen by the witnesses among the various objects of curiosity at Drawbaugh's shop several years before they testify is necessarily unreliable when it is attempted by observers who had no knowledge of the mode of operation or of the infernal organisation of the instruments. Such witnesses could not appreciate what they saw even if they examined the instruments. Most of the witnesses belong to this class. Indeed, the greater portion of them do not profess to identify the exhibits positively. Some are more certain than others that particular exhibits are the instruments they saw. Exhibits F, B, and C are fragmentary remains of instruments, and their value depends upon Drawbaugh's description of the operative parts that no longer exist. Scores of witnesses testify to seeing the teacup device resembling Exhibit F, and the tin can device resembling Exhibit B, but the identification of the other exhibits prior to the date of Bell's patent is comparatively feeble.

The appearance of Exhibits F, B, and C is sufficiently peculiar and distinctive to impress the memory of those who saw them. On the other hand the other exhibits are not of this character, and all that ordinarily the witnesses can safely say of them is that five years or more before testifying they think they saw or used a small walnut box externally resembling I or A or E or D.

It may be said generally of all the testimony of the witnesses who attempt to identify exhibits, that it is mainly valuable when it proceeds from those who used the instruments which they think they remember, and obtained results. They must remember the results obtained much better than the minor differences of appearance presented by the instruments. Granting that Exhibits F, B, and C would be likely to be remembered, what shall be said of the value of the testimony of scores of witnesses who state that they tested these instruments, or saw others test them, and they articulated perfectly, when it appears by the most authentic test that these instruments were incapable of such articulation.

In March, 1882, after most of the proofs in the case had been taken, a test was made of the capacity of the exhibits to transmit speech in the presence of the counsel and the experts for the respective parties. It is not accurate to say a test was made of the exhibits, but reproductions of F, B, and C were made by Drawbaugh, and, as rehabilitated by him, were used for the test. Whether these were honest reproductions no one can tell, but such as they were they were experimented with by Drawbaugh before they were subjected to the test. Whatever else that test demonstrated, it proved that articulate speech could not have been practically communicated through Exhibits F, B, and C, at Drawbaugh's shop or under similar conditions; and that only fragmentary or incoherent speech could be occasionally and exceptionally rendered by the reproduced instruments which had been experimented with privately before the public test. The proofs show that all along to 1878 Drawbaugh exhibited his earlier instruments F and B to spectators, and used them as his talking machine, sometimes showing or using both together, and sometimes one of them. The testimony of the defendants' witnesses, Springer, Moore, Musser, and Bayler is pertinent upon this point, and has been referred to. How is it to be explained that he used these crude instruments in 1875 and 1876 as his talking machine if he had the better instruments, especially such instruments as E and D? But in view of the fact now shown that these earlier exhibits are incapable of satisfactory articulation, what confidence can be placed in the rest of the testimony produced to identify exhibits? If the witnesses are mistaken in identifying these very characteristic instruments, and in recalling the results obtained through them, little reliance can be placed upon the identification of the other instruments, or upon the statement of the results which the witnesses think were obtained through them. If these witnesses are mistaken in the dates which they fix for the occasions they speak of, their testimony can be reconciled with all the probabilities of the case. And the reasonable explanation of their testimony is that those witnesses who really saw or used the latter exhibits did so in 1876, 1877, 1878, and later, instead of on earlier occasions.

* Ayrton and Perry: Letter published in 1877 by Meiklejohn (Yokohama).

See also *Journal de Physique*, 1881, xvi., p. 68, and May, 1880: "Différence de potential des couches électriques qui recouvrent deux métaux en contact."

Digitized by Google

The proofs on both sides lead to general conclusions that Drawbaugh was not an original inventor of the speaking telephone, but had been an experimenter without obtaining practical results until the introduction of the instruments into Harrisburg. It is very probable that after reading in the *Scientific American*, loaned by Mr. Shapley, in October, 1876, the article purporting to describe Bell's telephone, but which really described better the Reis apparatus, he undertook to improve his old devices. At that time, or after, he had examined the telephone instruments at Harrisburg, and carried one of them home to study, he may have altered the organisation of his instrument, and made the intermediate exhibits between F and D. If he exhibited them at his shop, and was able to transmit speech through them, this fact will account for the testimony of the witnesses who identify those exhibits, and may be mistaken as to the time they saw them. The real history of his talking machine is known only to himself, and it will not be profitable to conjecture when he made the advanced instruments which he claims to have made in February, 1875, and the later instruments.

It may be that in discrediting his narrative and rejecting the theory of the facts which rest upon it, the value of the corroborative testimony has been under-estimated. However this may be, no doubt is entertained as to the conclusion which should be reached upon the proofs.

Succinctly stated most favourably for the defendants, the case is this: One hundred witnesses more or less testify that on one or more occasions which took place from five to ten years before they think they saw this or that device used as a talking machine; they are ignorant of the principle and of the mechanical construction of the instruments, but they heard speech through them perfectly well, and through one set of instruments as well as the other. This case is met on the part of the complainants by proof that the instruments which most of the witnesses think they saw and heard through were incapable of being heard through in the manner described by them, and further, that the man who knew all about the capacity of his instruments never attempted to use them in a manner which would demonstrate their efficiency and commercial value; and on the contrary, for ten years after he could have patented them, and for five years after they were mechanically perfect, knowing all the time that a fortune awaited the patentee, and with no obstacles in his way, did not move, but calmly saw another obtain a patent and reap the fame and profit of the invention.

Without regard to other features of the case it is sufficient to say that the defence is not established so as to remove a fair doubt of its truth; and such doubt is fatal.

The observation of an eminent commentator may be quoted as apposite to the case: "No form of judicial evidence is infallible, however strong in itself; the degree of assurance resulting from it amounts only to an infinitely high degree of probability, and perhaps as many erroneous judgments have taken place on false or mistaken direct testimony as on presumptive proof." Best's Evidence, section 468.

A decree is ordered for complainant.

COMPANIES' MEETINGS.

Telegraph Construction and Maintenance Company (Limited).

The twenty-first ordinary general meeting of this Company was held on the 3rd inst., at the offices, 38, Old Broad-street, under the presidency of Sir Daniel Gooch, Bart., M.P.

The MANAGER (Mr. William Shuter) read the notice convening the meeting.

The CHAIRMAN: Gentlemen, the first resolution I have to propose is, "That the report and accounts to the 31st of December, 1884, submitted to this meeting be and the same are hereby received and adopted, and that a dividend of 36s. a share, in addition to the 12s. interest or interim dividend paid on June 30th, 1884, be paid upon all the shares of the Company for the year ended December 31st, 1884, and that such dividend be paid free of income-tax."

The MANAGING DIRECTOR (Vice-Admiral Sir George H. Richards, C.B., F.R.S.) seconded the motion.

The CHAIRMAN: Before putting the resolution I will just call your attention to a few facts mentioned in this report. Fortunately in this Company we have not to make long speeches. The report will show you that we have manufactured and laid (some of it was manufactured in the previous year) 875 miles of cable for the Eastern Extension Telegraph Company, to connect Saigon with Tonquin in the China Sea. That was laid successfully in February last. The Brazilian Submarine Telegraph Company's duplicate lines between Madeira and St. Vincent, and between the latter island and Pernambuco, part of which were manufactured in 1883, amounting in all to 3,030 miles, were laid between the months of March and July, and three repairs were effected in that Company's original cables during the same time. The Direct Spanish Company's duplicate cable between the Lizard and Bilboa, 473 miles in length, was laid during the month of May. A cable, 40 miles in length, has been laid across the Strait of Sunda (between Java and Sumatra) to replace the one destroyed by the volcanic eruption of 1883. Sundry lengths of cable, amounting to about 660 miles, have also been laid in the Australian and China Seas, to make good the existing lines of the Eastern Extension Telegraph Company, the portions thus renewed having been picked up. These services were carried out at various times between the months of February and August. Several short lengths of cable have been manufactured during the year for several telegraph companies; the German Union Telegraph Company's cable between Hamburg and Heligoland has been repaired; and in the month of December, the "Sunk" Light vessel at the mouth of the Thames was connected by a cable with the Postal Telegraph Office at Walton-on-the-Naze, as an experiment, for the Corporation of the Trinity House. The "Sunk," as perhaps you remember, is a light ship, and it has been the attempt of our officers to enable a communication to be made between the light ship and the shore in order to effect telegraphic communication. I daresay many of you were at the Exhibition last year at Kensington, and may have seen the model of the ship and appliances then proposed. That ship has been connected with the shore. Unfortunately we have had more trouble than we expected, and the thing has not up to the present moment been a perfect success; but the ship is there now, and we are beginning again now with the view of trying to remedy the defects. I hope our efforts will be successful. I am sure we must all be satisfied if we are able to carry out such a scheme as that, because it would be a very important thing to connect the different light ships on the coast with the land lines. We cannot promise success, but we know that our officers are doing their best, and have to a certain extent succeeded. Then we have also connected the Fastnet Lighthouse with the shore, and that was done during very bad weather. The consequence was, we were not able properly to land the cable on the rock on which the lighthouse stands, and it chafed across the edge of the rock and became broken; but we do not think there is much risk about making that perfect when we have proper weather to make the cable fast, so that there will be no chance of its chafing as on this occasion. If there is any question about any of these matters on which you wish me to give you any further information I shall be happy to do so. There is another work we are carrying on, as you are aware—the lighting by electricity of the Paddington Station. That work, I hope, will be ready in about a couple of months. I must confess it has taken longer than we had expected to get ready, but it is the largest work that has been done in England.

The MANAGER: The largest work in the world.

The CHAIRMAN: Well, probably. I know it has been exceedingly well done, and I hope when completed it will be a great success, and will be a sort of pattern card for this Company for making any similar kind of work in other places. As you are aware, we have important Provisional Orders for lighting the parish of St. James's. Well, of course it is a new thing, and we were very anxious to have some experience and knowledge of its cost before we went into so large a matter as the lighting of St. James's parish. We were therefore very glad to have the opportunity of lighting a large station like Paddington, which is all in one control and not subject to a great number of houses, and it will give us that experience which will enable us to judge of our mechanical and economical efficiency to undertake the lighting of large towns. The experience will be very valuable to us, and I think we were very wise in getting it before we embarked further in this scheme. The report mentions that we are building a new ship to replace some that are not so young as they were. That will be ready in the course of the summer. I may mention that the Government have chartered two of our ships, the "Calabria" and the "Kangaroo" for the purpose of going to Suakim to condense water for the troops. They are engaged for three months certain, and so much longer as the Government like to keep them. These ships are fitted with large cable tanks, which enable them to store large bodies of water on board, and such, perhaps, are the only ships afloat that are capable of doing that work efficiently. I do not think there are any matters in the accounts that I need mention, but I shall be glad to do so if there is any question, and I shall also be glad to explain any item. I cannot convey an idea of these accounts, but you have them in your hands, and if there is any item you wish explained, in so far as I can, I shall be glad to do so. I now move the resolution.

A SHAREHOLDER said he would like to know the estimate of the new ship, and out of what funds she would be paid for?

The CHAIRMAN: She will be a vessel of about 1,200 tons, and will be paid for out of the steamship reserve. We have ample funds for that.

The SHAREHOLDER said he wished to know the price.

The CHAIRMAN: I do not know whether that is quite wise. Is it? She is being built by Messrs. Laird, of Birkenhead, and we beat down the price as much as possible.

Mr. WAKEFIELD thought that everything the Chairman had said was very satisfactory. The only question he would like to ask as an old shareholder was what opinion the Directors had formed of the lighting at Paddington—whether it would well answer the purpose of the Company in undertaking it? He knew two or three persons who had lighted large establishments with electric light, and it did not seem to answer at all. It was much more expensive than gas, and not of much advantage. He could understand that in a large place like Paddington Station it was a very great boon, but did the Directors think it would pay the Company?

A SHAREHOLDER asked whether the Company had any good cable orders on hand.

The CHAIRMAN: The quantity of cable work on hand for the current half year is about 1,000 miles. We have half of that completed. As to the question of Mr. Wakefield, I may say that I do not believe the Paddington lighting will pay us, but it will pay us in a form—we shall know exactly what it will cost. I think our engineer somewhat under estimated the cost of the work, but I do not like to deceive you into supposing that it will not cost us something as an experiment. As to its success I have no doubt. We have worked the electric light on the platforms there for three or four years, and I have never had any difficulty in connection with it except for the first few months after starting, when our engine did not work thoroughly well. Since then there has been no difficulty, and that it is a vast advantage to the railway company there is no doubt. The porters can see exactly what they are doing.

A SHAREHOLDER asked whether the result would be such that other companies would take it for their stations.

Digitized by Google

The CHAIRMAN: I hope it will answer. A gentleman says he knows several cases where the electric light does not answer, but I know other cases where it does. We must take a view apart from cost as to house lighting. I do not care whether it costs me £5 or £10 more, but I think, having a perfectly pure light, I should save the extra cost twice over by no damage being done to my pictures, decorations, and works of art. Here is where there is one direct advantage from the electric light. I do not think it would affect the question if it were £2 or £3 more, but I believe those who are using it do not find it more costly than gas. In large places the electric light will come out better still in comparison with gas as to cost.

A SHAREHOLDER wished to know if anything had happened during the year to their large steamships. In last year's report it was stated that the ships were in efficient condition, but in the present report it was stated that in view of wear and tear of some of them it had been decided to build a new vessel. He did not quite understond this, unless something had occurred. It was also said that the "Seine" was being supplied with new engines and boilers, and was undergoing a thorough refit. He could not understand the necessity for that in view of what was stated last year as to the condition of the ships; and if anything had happened since he thought the shareholders ought to know it. It was stated that the cost was to come out of some fund which had been provided for the purpose, but he saw no mention of that fund in the balance-sheet. There was an item, "By property, consisting of freehold and leasehold premises, machinery, plant, stocks of stores, materials, leases, &c., £483,973." He and some other shareholders would like to know the value of the freehold premises, and what was the amount they had invested in ships, what was the amount in freehold premises, and so on. They had a large property at North Woolwich which was shut up and, he supposed, unremunerative. He did not think it ought to remain idle. Then in the second paragraph of the report it was stated that they had earned so much net profit, and it was a satisfactory statement that the amount enabled the payment of a dividend of 20 per cent.; but present investors only got about 6½ per cent., which, in his opinion, was nothing very extraordinary for a trading concern, though it was very good. What he wanted to point out, however, was that the shareholders were only informed of the net profits; they knew nothing about the gross profits or the establishment charges, and many other matters which in such an undertaking they were, he considered, entitled to know. He would also like an explanation of the item on the other side of the balance-sheet—the lump sum of £485,000 against the item of debts owing by the Company, and reserves for insurance, debentures, and contingencies, and suspense accounts for unfinished work. They had cash in hand £198,000, and he thought there was no necessity for their having any very large amount of trade debts.

The CHAIRMAN: You are reading from last year's accounts as far as I can understand, though there is not much difference.

The SHAREHOLDER: Yes, they are about the same.

Mr. WILLIAM ABBOTT presumed that the last speaker was a new shareholder. About twenty years ago he (Mr. Abbott) made the same mistake in asking similar questions; but he had grown wiser, and was quite content to take the Chairman's advice and study the accounts. After twenty years' experience he was satisfied, so long as Sir Daniel Gooch presided over the affairs of the Company, assisted by such able colleagues, to accept what was given him with thanksgiving. He had often noticed that the Chairman came before the shareholders in a very meek spirit, indicating no cable work to do, but still the same 20 per cent. dividend came round each year. He would recommend any sceptical shareholder to study the map in that room, when he would see the enormous amount of work they had carried out, and he would not only be satisfied with what the Company had done but would be proud to belong to such a company. He was at the recent meeting of the Anglo-American Telegraph Company, when Lord Monck announced that the only four cables then doing the work of Atlantic telegraphy were the four laid by this Company. They saw from the map the small spot which England occupied upon it, yet she was the pivot upon which the whole trade of the world turned, in consequence of the enterprise in which the Company engaged twenty years ago, and from which the shareholders were now reaping the fruit. He asked no questions on the accounts. The purchase even of a new ship did not seem to be regarded as any very serious matter by the Directors, and no call was made on the shareholders to subscribe for debentures to meet the cost. They might sing, "We've got the ships, we've got the men, and we've got the money, too," for there was no doubt whatever that those important compounds were present in their Company. They had a staff second to none in the United Kingdom; and the wonderful zeal thrown by them and the Board into everything connected with the undertaking, with the enormous power of their cash reserves, enabled them to do what they did for the shareholders.

The CHAIRMAN: As to the question of an honourable proprietor he knows, if he has been long a shareholder in this Company, the reason why we have not set out all those figures and details. It would be absurd in a Company like this to give all the information that partners in a firm of three or four receive. Our affairs are larger, and require a certain amount of reservation. A great many years ago we adopted a form of accounts with that view, and you must put a certain amount of confidence in your Directors. The figures comprising that large item of £485,000 are the value of our premises and other properties. If the honourable shareholder is a man in trade, he must know that that amount is composed of thousands of items—in fact, everything we have to carry on our business with. To put all that information in our report would require volumes, and then you would not understand it. As to the ships, it is quite true that the "Seine" and the other ships were in thorough order twelve months ago; but we could not know then when new boilers would be required. The "Seine" has been sent to Messrs. Laird's to be re-boilered and put in thorough order. You must have some of the ships going occasionally into repair, while others are in an efficient condition. The cost of all that repairing comes out of your business—the revenue, but the cost of the new ship will come out of the reserve. I do not know whether I omitted to answer anything. The Chairman then put the resolution, which was carried unanimously.

The retiring Directors, Sir Geo. Elliot and Mr. Philip Rawson, and the Auditors were next re-elected.

On the motion of Mr. WM. ABBOTT, seconded by Mr. WAKEFIELD, a vote of thanks was passed to the Chairman for presiding, Mr. ABBOTT remarking that the Chairman was always in his place at their meetings, and always voting on the right side in the House of Commons.

The CHAIRMAN: I am very much obliged to you. We try to do our best. I am sure you are all conservatives as to having a good dividend, and that you will not object to that as a conservative measure at any rate.

The proceedings then terminated.

South-Eastern Brush Electric Light and Power Company.

An adjourned general meeting of the shareholders in this Company was held on the 27th February at the offices, Cow Cross-street, E.C., under the presidency of Mr. T. Fry.

The CHAIRMAN: Gentlemen, this is an adjourned meeting for the purpose of receiving the report of the committee appointed at the ordinary general meeting in December last, and you will have to consider to-day and to decide whether you will receive or reject that report. Now, the date of this meeting has been fixed expressly to suit the convenience of members of the committee. Certain dates were given us on which we were told it would not be convenient for them to attend, and we fixed this day. Notwithstanding that, it does seem strange that, not content to wait till an expression of opinion had been given by the shareholders, one of the members of the committee, in conjunction with a shareholder, has obtained signatures to a requisition calling upon the Directors to convene an extraordinary general meeting for the purpose of considering proposals to wind up at once, and to appoint two of their members as liquidators. This is a very nice little family arrangement, and probably may be very agreeable to those who propose it; but we, the Directors, shall have something to say to the shareholders before they appoint as liquidators gentlemen who have taken up such an attitude to the Company that we are suffering at this moment to a very serious extent. We hear that our business at Colchester is stopped from being extended simply from the fact that, owing to the reports which have appeared and the statements made by the committee, our customers will not, we are told, go to the expense of laying on a supply of the electric light because they do not know how long it may be continued [A Voice: Quite right]. It appears to be quite right from your point of view, but from ours we say we are suffering. It is now for you of the committee to give some reasons why your report should be received, and it is for you to propose its reception and adoption.

Mr. REGINALD BRAITHWAITE: I will not waste time by answering the Chairman's speech, though I have a complete answer to all he has said; but I will simply move "That the report of the Committee of Inquiry be adopted by the shareholders."

Mr. COMBERBACH seconded the motion.

Mr. C. H. STEWART: It now becomes my duty to give some reasons for the course pursued by the committee and the report they have issued to the shareholders. I must call you back to the institution of this Company in 1882, and I shall also call your attention to a few of the items contained in your first statement of accounts. I shall also go into the question of the arrangement as between you and the Consolidated Company. I charge the Directors with making a most improvident arrangement. In their report presented here they allude to the arrangement made here in the first place in regard to the experiments carried on by our paid officials, who are paid high salaries for attending to the business of this Company. These are the men who during their term of employment here in this Company were engaged in those experiments. What for? For this Consolidated Company. You invented machinery for this Consolidated Company. As to the commitments of capital, the amount spent in time and also in regard to those experiments and appliances in the office in Victoria-street should have been carefully taken into account, and should have made you very careful in those arrangements with these officials. I never heard of such a thing—and many of the shareholders may be ignorant of it—that in arranging with a company for this affair with 100,000 shares you allot to those men—your own *employés*—60,000 shares in that company, retaining only 20,000, or one-fifth, for this Company and the same for the Provincial Brush Company. I allude to that just by the way, because I think most of the gentlemen here are also shareholders in the Provincial Brush Company. I there charge you with making a most improvident arrangement, and giving the power entirely into your own *employés'* hands. To men whom you ought to have kept a tight hold on you gave control of the Consolidated Company, and, beyond that, you committed this Company to find £10,000 capital towards carrying on the business of that company, and you took debentures, which from what I am advised are of such a nature that you cannot put them in force, as they are dependent on earnings. You have not shown us, the shareholders of the South-Eastern Company, that we have made any profit. You have refused to give us any information as regards the working of this Company. I find in the various items of the account that this Company is bearing all the brunt of the expenses themselves in testing the quality of these batteries which are now at Colchester, with the view of testing the B.T.K. system.

Digitized by Google

In addition to the £10,000 you committed this Company to in hard cash, you go beyond that, because you incur an expense of over £7,000 in establishing this lighting at Colchester, which is losing the Company something like over £1,000 a year [The Chairman: No, no.] That is how the account stands as far as I am able to judge. If you take into account the loss on working, and the depreciation of plant, I think you will find it is fully £1,000 of loss. Well, then, is it not time we should put a stop to this extravagance? Can you say it is too soon, when you find in the last statement of accounts—concessions, preliminary expenses, and so on—an item put down at £14,711? What is the value of that asset? The concessions, as regards your arrangement with the Brush Company, I consider in a measure worthless; and I take it that this item of £14,711 is almost worthless. We do not mean to say that we shall not obtain something; but it will be very small indeed. As to the amount paid for provisional orders, I look on that as entirely lost, because no man with the knowledge which I and others here have would ever attempt to light towns on those provisional orders, which would entail even heavier loss than that at Colchester. I think, as to Colchester, that you may take it that a very large amount of the expenditure there is lost. I do not know what the plant would realise if it had to be removed from Colchester. The only chance would be if it could be sold to the Corporation, or to a private company. If, however, you value it at the full amount stated, you have still the loss of more than one-third of your capital [A Voice: Far more]. Then we come to stock and office furniture.

The CHAIRMAN asked of what use it was to go into the items mentioned by Mr. Stewart. The accounts had, he said, been discussed, and the meeting was to consider the report of the committee.

Mr. STEWART: I do not treat these items as assets. They are fictitious. You have no assets except the plant at Colchester, the stock in the office, the debentures of the Consolidated Company, and 20,000 shares. I believe a very large number of those have been sold from 1s. to 3s. each. You therefore see that the greater portion of the capital is lost. In the working of this Company, what do I find? It has been worked most extravagantly. It was said for some time that the Board were most moderate in their fees, but I find they have been about £2,300 during 1883 and 1884, and I heard from the Chairman that they were not going to take fees. I hope if the Company goes into liquidation that they will consider that, and consider that they have had ample, and more than enough, in the two previous years, and will do some little justice to the shareholders by foregoing any further fees. This Company and the Provincial are kept on merely as "milch cows" for providing funds for the Consolidated Company, over which you have not the control. These patents which cost this Company so much, not only in time but also in expenditure—all this is entirely in the interest of the Consolidated Company, because you make over the patents, which we have absolutely made such sacrifices for on account of the Consolidated Company, to the Consolidated Company. You also charge the expense of office lighting to this Company which was necessary, more especially for testing the batteries of the Consolidated Company. Everything is charged to the South Eastern Company—at any rate to a larger extent than the Provincial Company; but both are milch cows for the Consolidated Company. I think I have made out a sufficient case for the immediate winding-up of this Company.

Mr. BLEWITT asked whether the report of Professor Forbes had been received, and if not whether the Directors or officers had had any intimation of what the nature of it would be.

The CHAIRMAN replied that a private and confidential report had been received, which was exceedingly satisfactory to the Directors of the Consolidated Company. That would be forthwith followed by a report which they would be allowed to publish, according to their agreement with Professor Forbes. That report the shareholders would have shortly. For the present he would state that it was very satisfactory.

Mr. BLEWITT: Why is it, if £50 was paid to Professor Forbes to make a report to this Company ——

The CHAIRMAN: Not to this Company.

Mr. BLEWITT: £50 of our money. It is stated so in your own report.

A SHAREHOLDER: I second the winding up.

Admiral Sir E. A. INGLEFIELD, C.B., observed that he was one of the liquidators of the Metropolitan Brush Company. They had been able to collect a great deal of information—not only useful for that company, but for all companies connected with the Brush Company. On that ground he spoke to the subject that the Company be wound up, or that the report of the committee be adopted. It would be for the shareholders' benefit, as in the case of the Metropolitan Brush Company. What remained would be saved, and economy would be practised, if the winding-up the voluntary liquidation were conducted in the same manner as that in connection with the Metropolitan Brush Company. He was satisfied from all he had learnt that nothing was to be made out of the provisional orders. The time might come when the electric light might be useful all over the world, but that time had not yet arrived. He spoke not only from the information he had obtained as a liquidator, but also from the information he obtained as Chairman for two years of the Maxim-Weston Company.

Mr. BLEWITT thought that any report of the committee would be justified by the circular, signed by Mr. Fry, which had been issued for the Directors, and by the speech of the Chairman. The committee saw that there was an afterthought and an intention to let the miserable existence of this Company drag on as far as possible. The only two points which bore Mr. Fry's name were these—first, that the committee were going to destroy the concern and then try to sell it. If, however, they went to the Anglo-American Brush Company they would go with this position: "We want to sell this concern to you. If you do not buy it we shall wind up." [The Chairman: "Just so."] As to the Colchester concession, the Directors held out a faint hope that it was going to be taken over by the Corporation or some private company. In either case, however, he presumed that that would have most likely happened when it had not been proved that the whole thing was a failure. But the Directors had waited until the whole thing had proved to be a failure, and now they held out the suggestion that the Corporation or some private company was going to take it over. How long was this Company to last—until the Directors found out whether the Corporation or a private company were going to buy it? He thought the committee had exercised a wise discretion in deciding to put an end to the Company.

Mr. J. BRAITHWAITE, jun., said he thought it right to say, as one of the Directors of the Anglo-American Brush Company, that the Directors of this Company, by their prudent and far-seeing policy, had made arrangements by which they had given over their concessions to the Anglo-American Brush Company. They had nothing to offer to that Company, and he had authority from the Anglo-American Company to say that they were not prepared to consider any proposal as to offering anything for the assets of this Company. Any suggestion of the Chairman of that sort was, he said, merely an endeavour on the part of the Directors to keep themselves in office a little longer and take a few more fees, till they had completely gutted the Company, and transferred all that remained to the Consolidated Company.

The CHAIRMAN: We are obliged to Mr. Joseph Braithwaite for coming and telling us that the concessions held by this Company from the Anglo-American Company are worth nothing.

Mr. BRAITHWAITE, jun.: I did not say so. I said we have got them, you having parted with your birthright.

The CHAIRMAN said he admired the candour of Mr. Joseph Braithwaite, but how did it assist the committee? The committee had said: "Go to the Brush Company. The Midland Company have made an arrangement with them, and so have the Great Western Co., and therefore go to the Brush Company." Now, however, they were told it was useless to do that; but all this would have to be discussed further. The present meeting would decide nothing on that point, because the Directors must call a meeting for considering a winding-up. Mr. Braithwaite had said that the Directors would wait in order to take more fees; but as they had had nothing for fifteen months, he asked that gentleman to admit that he had made an unfounded charge.

Mr. STEWART desired to make an explanation as to the intimation the committee gave stating that the Anglo-American Brush Company would be prepared to treat with this Company. So, he maintained, they would have been. At that time there were calls that could have been made to the extent of £10 a share, and the Brush Company were prepared to take over the whole matter. This, however, would have been going from Peter to Paul, and the wish of the committee had been to prevent the making of calls.

Mr. BRAITHWAITE, jun., said he was quite ready to withdraw anything he had said in error affecting the question of the Directors' fees, but nothing else. It had seemed strange to him that the Directors, with this meeting pending, had made a call of 2s. 6d.

The CHAIRMAN stated that liabilities had to be met, and the shareholders were told at the meeting on the 22nd December that a call would be made in the early part of this year. He thought they might now vote on the motion for the reception and adoption of the report of the committee; but before taking the votes he wished to state that he would object to any one voting who had not paid the call. He would not take the vote of any one who had not paid the call. After counting the votes, he said: Well, gentlemen, there are only in the room four others than ourselves who are entitled to vote, and therefore I declare the resolution lost.

Mr. BLEWITT demanded a poll.

The CHAIRMAN: You are a shareholder, but you cannot vote, as you have not been two months on the register.

Mr. BLEWITT asked what course the Directors would take, in the event of a poll, with regard to the lost proxies. A whole heap of proxies had been lost in the offices.

The CHAIRMAN: We have a list furnished by you.

Mr. BLEWITT stated that that was not so. He explained at the last meeting that as to a portion he had a list, and as to a portion he had not. If a poll were decided in favour of those who demanded it, well and good, but if decided against them it must be abortive, because of the lost proxies.

A SHAREHOLDER: Who stole the proxies? [laughter.]

The CHAIRMAN said they would admit all the proxies, but only those could be used as to which the call had been paid.

Mr. BLEWITT said that that could not be done, as the Chairman did not know what proxies had been lost.

The CHAIRMAN said that another meeting would be called, probably in ten days, to consider the proposal for winding up, and the matter could then be discussed.

Mr. STEWART wished the press to know that the resolution was lost by the votes of the Directors only.

The CHAIRMAN: No, no. There are others [A Voice: Paid nominees].

Mr. BLEWITT said he would recommend the withdrawal of the poll if the Directors would give an undertaking not to issue anything.

The CHAIRMAN declined; and in further reply to Mr. Blewitt respecting the proxies, stated that circumstances had altered since the general meeting. The Directors had proxies superseding some of the others. Other shareholders had not paid their calls, and some had transferred their shares.

A SHAREHOLDER: You had no right to make a call with this meeting pending.

The CHAIRMAN replied that he knew his duties as chairman, and they had been perfectly in the right to make a call. They were also right in refusing to accept the votes of those who had not paid the call.

A SHAREHOLDER: The call was made in violation of the pledged word of the Directors.

The CHAIRMAN repeated that at the last meeting the shareholders were told that a call would be made in the early part of this year.

Digitized by Google

A SHAREHOLDER: Do you object to receive a call for the purpose of a poll?

Admiral INGLEFIELD asked what the Directors proposed to do next?

The CHAIRMAN: To call a meeting to consider the proposal for winding up.

Admiral INGLEFIELD: Do you pledge yourselves to support that, or will you get proxies?

The CHAIRMAN: Why should we pledge ourselves, unless we know what you are going to do?

Mr. BRAITHWAITE, jun.: You have made the call obviously for defeating the voting at this meeting. I contend that this meeting is an adjournment of the one commenced in December, before any call was made; and if we were entitled to vote at the commencement of the meeting we are at the end. Will you pledge yourselves to make no further call before the next meeting?

The CHAIRMAN read from his speech at the last meeting, and stated that the shareholders were told distinctly on that occasion that the Directors would "probably make a call of 2s. 6d. in the early part of the year."

Mr. BLEWITT: The Directors are practically the Directors of the Consolidated Company, or a majority of the Board. What did they do immediately it was suggested that a committee of investigation should be formed? They served a notice, at the instance of the Consolidated Company, on the South Eastern and Provincial Brush Company, calling up the whole balance of the debentures.

The CHAIRMAN: We shall have an ample opportunity of discussing this. Having declared, and advisedly, that the resolution for the adoption of the committee's report has not been carried, was lost, I now must, in order to complete the business, move "That the Directors' report and statement of accounts, presented on the 22nd December last, be and are hereby received and adopted."

A SHAREHOLDER: That proves that we are holding the adjournment of the meeting of the 22nd December.

The CHAIRMAN: I move this at all events.

Mr. WAPSHARE seconded the motion.

Mr. BRAITHWAITE, jun., proposed as an amendment that the consideration of the motion be adjourned until after the next meeting.

This having been seconded,

The CHAIRMAN put the amendment, and declared it lost.

A SHAREHOLDER: The amendment was carried by the show of hands.

The CHAIRMAN: I declare it lost, because you are not entitled to vote.

Mr. BLEWITT: Let me ask you to declare on this resolution that you lost the show of hands.

The CHAIRMAN: I declare it lost. I am not going to recal that.

Mr. BRAITHWAITE, jun.: Will you tell us the votes? We ask you to count the votes.

The CHAIRMAN: I do not count the votes. I have declared for the resolution. I will not count the votes.

Mr. BRAITHWAITE, jun.: The Chairman refuses to count the votes of the meeting.

The CHAIRMAN. Of those who have not paid their calls.

Mr. BLEWITT: Would it not be well to adjourn the poll?

The CHAIRMAN: There is no poll.

Mr. BLEWITT: I demand a poll on both points.

The CHAIRMAN: Have you demanded a poll on anything?

Mr. BLEWITT: I asked you whether, for the purpose of demanding a poll, and for the shareholders to put themselves in order in that respect, you would accept the calls and then allow a poll to be demanded.

The CHAIRMAN: Yes; but it is not our business to receive the money. If calls are paid we will receive the votes; but what is the object?

Mr. BLEWITT: The object is to prevent you, by circular, stating to the shareholders that this resolution of the committee has been rejected, and that the resolution adopting the report and balance-sheet were adopted without your being challenged.

The CHAIRMAN: I pledge myself that we should do nothing of the kind. We should simply tell them that this meeting was mere waste of time.

Admiral INGLEFIELD asked whether it was the desire of the Directors to keep the Company going on, or whether they were with the committee in the desire to see the Company wound up.

The CHAIRMAN stated that the Directors had in their circular told the shareholders what they would do. They represented large holders.

Mr. R. BRAITHWAITE: My interest alone is nearly as much as that of the whole of the Board.

The CHAIRMAN said that the only interest of the Directors was to make the best of the position for the general body of the shareholders.

A SHAREHOLDER: Then why did you not wind up sooner?

The CHAIRMAN: Because we did not wish to do what you are doing—destroy what we possess.

Mr. BLEWITT: Is it the intention of the Directors when the calls are paid to pay over the balance to the Consolidated Company?

The CHAIRMAN: As required.

The proceedings then terminated.

A CIVIL and PRACTICAL MECHANICAL ENGINEER, of great experience, is returning again to the East the end of the present month. Has a knowledge of the languages, having resided in the far East for upwards of 20 years. Is now desirous of communicating with firms with a view to act as an AGENT for the construction of Iron Bridges, &c., Gas Works for small towns, and also for the introduction of the Electric Light, Telephones, and Electric Bells, and for general engineering.—Address to Aberleigh Lodge, Trewsbury-road, Sydenham, S.E.

ELECTRICAL ENGINEER is DISENGAGED. Has had considerable experience in Electric Light Installations, Land and Ship, in manufacture of Dynamos, Accumulators, &c.—Address S. J., *The Electrician* Office.

EMPLOYMENT WANTED by an ELECTRICAL ENGINEER, who has had experience in Arc and Incandescent Lighting; is a fair draughtsman, and accustomed to wiring and testing; knowledge of foreign languages. H. E. M., Office of this Paper.

TELEPHONE.—ENGINEERS desirous of TENDERING for the Construction of 7 miles of WIRE, send name and address to J. and W. BEANLAND, Bradford, Yorks.

PATENTS, DESIGNS, AND TRADE MARKS ACT, 1883.

In the matter of Letters Patent granted to Herbert John Haddan, of 67, Strand, in the City of Westminster, for "Improvements in Apparatus for the Generation and Application of Electricity for Lighting, Plating, and other Purposes," a communication to him from abroad by Charles Brush, of Cleveland, Ohio, United States of America, dated the 18th day of May, 1878, No. 2,003,

NOTICE IS HEREBY GIVEN, that The Anglo American Brush Electric Light Corporation, Limited (the assignees of the said Letters Patent), have applied under Sections 18 to 21 of the Patents, &c., Act, 1883, and Rules 48 to 56 of the rules made thereunder, for leave to further amend the Specification of the said Invention. A copy of the said Specification, as proposed to be amended, can be inspected at the Patent Office, and full particulars of the proposed amendment were published in the official *Journal* of the Patent Office, issued on the 24th February, 1885, No. 120, page 532.

Any person or persons intending to oppose the said application must leave particulars in writing of his or their objections to the proposed amendment at the Patent Office, 25, Southampton-buildings, Chancery-lane, London, W.C., within one calendar month from the date thereof.

Dated this 24th day of February, 1885.

H. READER LACK,
Comptroller-General.

MESSRS. OPPERMANN BROS. beg to announce that they have the following MACHINES, &c, FOR SALE, prior to stock taking, at greatly reduced prices:—

1	5	Light Experimental Dynamo		£7
2	12	,,	,,	20 each.
1	25	,,	,,	30

NOTES.

THE LUNDY ISLAND CABLE.—The Lundy Island telegraph cable has been successfully repaired, and is now in operation.

THE NATIONAL TELEPHONE COMPANY.—The Perth Exchange of the above company has now 111 subscribers on its list.

ASSAB BAY.—It is said that the Italian Government intend to connect their settlement on the east coast of Africa by cable with Italy.

THE TELEPHONE IN DENMARK.—The number of subscribers to the telephone at the end of 1884 in Copenhagen was 1,105, as against 516 for the previous year.

THE TELEPHONE IN PARIS.—There have recently been opened in Paris ten new telephone call offices. The number of such offices at present actually open for service is twenty-five.

THE INVENTIONS EXHIBITION.—We understand that the Henley's Telegraph Works Company have also supplied electric light cables for the forthcoming Inventions Exhibition, to the amount of £800.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 28th February are £2,403, as compared with £2,517 in the corresponding period of 1884.

THE GAULARD AND GIBBS SECONDARY GENERATORS.—We are in receipt of a comprehensive theoretical and experimental research, by Professor Galileo Ferraris, upon the Gaulard and Gibbs secondary generators.

THE TELEPHONE IN HOLLAND.—The telephone exchanges in Holland are already numerous, and the system is growing steadily into favour. The Nederlandsche Bell Telephone Maatschappy alone have some 2,400 subscribers on their list.

TELEGRAMS FOR THE WEST INDIES AND BRITISH GUIANA.—The cable between St. Vincent and Grenada is now repaired, and telegraphic communication is therefore restored with all places in the West Indies. The cable, however, between Trinidad and Demerara is still interrupted.

THE VITRITE HOLDERS.—The Vitrite Company have written to inform us that the defects complained of in the new vitrite lamp-holders have been remedied; they are the result, it would appear, of careless manufacture. We forbear to express an opinion pending the arrival of samples of the improved fittings.

ELECTRIC TRAMWAYS IN BERLIN.—It is announced that the managers of the Berlin tramways are about to experiment with a view to the use of electricity as the motive power upon the lines of Tegel, Pankow, and Schœneber. The current will be supplied by Faure-Sellon-Volckmar accumulators, placed within the car.

THE ELECRIC LIGHT AT BREMORE, N.B.—Messrs. Crompton and Co. are about to light the residence of Mr. John Fowler, C.E., at Bremore, N.B., by electricity. It is proposed to utilise water-power for the purpose of driving the dynamo, by means of two large turbines. The number of lamps will probably exceed three hundred.

SWEARING BY TELEPHONE.—A Cincinnati printer, who brought suit to compel a telephone company that had removed his telephone, because he made it a medium for the dissemination of habitual profanity, to replace the instrument, has lost his case, the Court holding that the company had the right to remove the instrument.

ELECTRIC LIGHT ON BELGIAN RAILWAYS.—By decision of the Belgian Minister of Public Works, all principal stations on the Belgian State Railways are henceforth to be lighted electrically, as it has been found that the electric lighting of the Luxemburg Station, Brussels, has led to a considerable reduction of accidents at night.

LONG-DISTANCE TELEPHONY IN BELGIUM.—A valued correspondent writes us from Brussels that, on the 4th inst., the Van Rysselberghe system of telephony was applied to the telegraph line between Brussels and Ghent. The double cornet receiver is used, and messages are transmitted with remarkable clearness when care is taken to articulate distinctly.

SUAKIM-TRINKITAT CABLE.—We understand that the Eastern Company's ss. "Chiltern" left Suez on Thursday for Suakim, carrying cable to lay between Suakim and Trinkitat. The order for laying this cable was received on February 22. The necessary cable for the work was at once taken from the store at Malta, and it is expected that the cable will be completed and at work by March 18.

THE PRINCIPLES OF ELECTRIC LIGHTING.—We have received a pamphlet by Mr. Sydney F. Walker, containing much useful information upon the subject of the construction and arrangement of electric light apparatus. The pamphlet, which embodies a paper read by Mr. Walker before the North of England Institute of Mining and Mechanical Engineers, is well illustrated, and discusses the merits of nearly every known dynamo and lamp.

THE VAN RYSSELBERGHE SYSTEM IN FRANCE.—*La Lumière Electrique* has, according to *L'Etoile Belge*, been misinformed in announcing that the French Government have decided not to adopt the Van Rysselberghe system in France; on the contrary, the Government have expressed their entire satisfaction with the experiments made between Rouen and Le Havre, and have confided to Messrs. Mourlon and Co. the appropriation of the line between Paris and Reims.

ELECTRIC LIGHT ON WAR SHIPS.—Some important experiments in electric lighting have recently been made at Wilhelmshaven. The training ship "Mars" has received an installation, costing about £1,500. The bridge of the vessel is illuminated by two arc lamps of 1,800 candle-power each, and a "searcher" of 20,000 candle-power, while the interior of the vessel is lighted by 300 incandescent lamps of 25 candle-power each. It is scarcely necessary to add that the experimental installation has given great satisfaction.

PROLONGED HOURS OF TELEGRAPH CLERKS.—We have received a letter upon this subject, calling our attention to the unnatural strain upon the eyes, the brain, and the wrists, &c., which is consequent upon the prolonged exertions of a telegraphist. With this and with the question of pay we have nothing whatever to do, and we must decline most emphatically to discuss so complicated and ungrateful a matter. The question is simply one of supply and demand; the views of the *employé* and of the employer are diametrically opposed to each other, and we do not care to endorse either of those views.

THE PROPOSED MONSTER LIGHT IN PARIS.—The proposal of M. Bourdais to erect an electric lighthouse 300 metres high, in Paris, is characteristic of the French nation. Whether that project will ever be carried into effect remains to be seen. M. Bourdais is sanguine; and perhaps as France has given us an International Society of Electricians, she may be able to confer the inestimable blessing of an international lighthouse

Digitized by Google

upon suffering humanity. The lantern will, it is said, contain 100 arc lamps of 20,000 carcels—say 140,000 candle-power each—or a total of 2,000,000 carcels. Truly magnificent !

CABLE STORES.—We have from time to time recorded the admirable work done by the Eastern Telegraph Company in laying cables and completing connections in periods of emergency. This they are able to do, because of the complete system for storing spare cable and foresight to keep a movable supply in store to provide in such contingencies as accidents and the exigencies of warfare. Tanks to contain the spare cable have been erected at Gibraltar, Malta, Syra, Odessa, Suez, Perim, and Zanzibar. In all, twenty tanks ; and these in addition to five cable ships, which of necessity carry spare cable.

LONG DISTANCE TELEPHONY.—Recent experiments in long distance telephony have been carried out in the Argentine Republic, the system being that of Van Rysselberghe. After the first few trials in Buenos Ayres itself, conversation was successfully maintained between Buenos Ayres and Belgramo, a distance of 22 kilometres (13·6 miles) ; between Buenos Ayres and La Plata, 70 kilometres (43·4 miles) ; and between Buenos Ayres and Rosario, 1,350 kilometres (837 miles). These experiments, which were coincident with the *fêtes* of the foundation of the Republic of La Plata, have given most excellent results.

ELECTRICAL WORKING OF TRAMWAYS AT BRUSSELS.—Advices from Brussels state that the Compagnie Belge et Hollandaise d'Electricité has at length overcome all obstacles connected with the electrical working of the Rue de la Loi Tramway, Brussels. The Faure accumulators, 48 in number and with 820 kilogrammes, or rather over 16cwt., of lead and oxide, giving out a useful effect of 66 per cent., are charged by dynamos put down for the purpose. The line, about a mile long and with heavy gradients, has hitherto been worked by horses ; but it is found that a saving of 30 per cent. is effected by electrical working.

SKRIVANOW BATTERY.—This battery, contained in two small boxes, 10in. long, 8in. wide, and 6in. high, consists of a number of cells, only an inch in width, in which zinc plates and chloride of silver are placed in certain proportions, with a weak solution of potash as the excitant. It is said to be sufficient for an arc lamp of 600 candles nominal, or for 75 small incandescent lamps. Local authorities contemplating a great expenditure upon gasworks, with all the inconvenience and perpetual annual cost, will do well to pause and consider what is being done elsewhere to provide at far less than the cost of gas a more brilliant and beautiful illuminant.

THE SOCIETE INTERNATIONAL DES ELECTRICIENS.—The first meeting of any importance of this society, which was to have been held in the Observatory in Paris on Sunday next, has been postponed for eight days. The proceedings will be private, visitors being admitted only upon presentation of a card of invitation in the names of Admiral Mouchez and the President of the Society. These may be had upon application to the members. There will be one or two conferences of electricians in a special apartment each evening. Other rooms for exhibits will be open daily from 1 p.m. until 5 p.m., and from 8 p.m. until 11 p.m.

THE ANTWERP EXHIBITION.—The exhibition works at Antwerp are being rapidly pushed forward, and the exhibitors have already commenced to arrange their stalls. The machinery section is notably in a very advanced state. The firms of Carels, Bollinckx, de Kerkhove and Cail, have nearly finished the foundations destined to receive the engines which they propose to exhibit. The municipal authorities of Antwerp are now making arrangements for a new line of tramways, between the L'Est Station and the exhibition buildings, upon which it is proposed to experiment with different systems of traction, steam and electric motors, &c.

THE TELEPHONE IN BELGIUM.—On the 8th of April next the public adjudication of the concession for the establishment and exploitation of a telephone exchange system in the town of Namur and the neighbouring communes will take place at the Bourse de Commerce of Brussels. The new exchange will be connected telephonically with the other towns in Belgium. The notice of adjudication contains the clause that the subscribers shall be enabled to transmit their messages over a distance of 200 kilometres (124 miles), by means of the aerial lines, and upon the Van Rysselberghe system, so that telegraphic and telephonic communications may be simultaneously exchanged.

A NEW PHOTOMETER.—A description of a new photometer has recently been laid before the Société Belge D'Electriciens by M. Wybauw. The white light of the electric arc lamps has hitherto presented great difficulties in the calculation of the candle-power of such lights. The photometers commonly used give erroneous results, in that the arc lamps of 5,000, 10,000, and 20,000 candle-power, according to the manufacturers' value, are not seldom found to be considerably below those figures. By the method of M. Wybauw the difficulties presented by the difference of flame and arc colour are surmounted, and by a calculation of a somewhat complicated nature the measurement may be made with mathematical exactitude.

THE ELECTRIC LIGHT IN THE SOUDAN.—We are informed that a number of sets of arc light apparatus have been ordered, of Siemens, Brush, and other manufacturers, by the Government, for immediate despatch to Suakin. It is proposed to use Brotherhood engines to supply the power required for driving the dynamos. We should suggest that fixed engines, requiring a bed plate, a suitable position where fuel is abundant, and being difficult of transport, are not likely to conduce to the perfect success of the projected installations. Traction engines would, in our opinion, be found of more practical value ; they could be utilised for the purposes of transporting fuel and water, and could be moved to any desired spot with less difficulty than the others.

ACADEMIE DES SCIENCES' COMPETITIVE PRIZES.—The prize which was granted in 1884 by the mathematical section of the Académie des Sciences for the best essay upon "Perfection in each Important Point of the Theory of the Application of Electricity to the Transmission of Work" has been further extended to the year 1886, the subject being the same. The prize consists of a medal, value £120. The essay for 1885, to which an equal reward is attached, is to be upon "The Origin of Atmospheric Electricity, and the Causes of the Development of the Electrical Phenomena in Storm Clouds." Competitive papers will be received up to the 1st of June, 1885, and must be accompanied by a sealed paper containing the name and address of the author ; this will not be opened until the prize has been adjudged.

A UNIVERSAL AGENT.—The *Western Morning News* says:—"There seems to be no end to the uses to which electricity is being applied. In commercial enterprise as well as in other directions it is now largely used, and one of the latest instances of this may be seen at the Army and Navy Hotel, in Victoria-street, Westminster. Here it is used to summon

Digitized by Google

the servants, illuminate the building, book seats at the theatres, call cabs, give notice of fire, communicate with places of business in the City, and convey the news of the day from every part of the world. In this as in other respects those who are responsible for the management of 'the Army and Navy' have kept well abreast of the times, and everything is done to secure the comfort and convenience of visitors, whether singly or in families."

THE ELECTRIC LIGHT AT THE MUSEE GREVIN.—The *Bulletin International des Téléphones* says:—The application of the electric light to the illumination of the Musée Grévin is perhaps one of the installations which has most satisfactorily demonstrated its superiority in a decorative sense, while the facility with which it lends itself to lighting purposes of all kinds leaves nothing to be desired. The installation comprises 372 Edison incandescent lamps of 8 and 16 candle-power; giving altogether a total intensity of 4,336 candles, and two arc lamps of the system Cance. The current is supplied by an Edison dynamo A, for 300 lamps, driven by an engine of 50 horse-power, supplied by Lecouteux and Garnier; the boiler being an inexplosible generator of the Collet system. The lamps are divided into 10 circuits, which are again subdivided in accordance with the requirements of the building. The two arcs are placed at the entrance to the museum.

JOINTS FOR INSULATED WIRES.—It has been stated that "bound joints" have cost a contractor a very large sum of money to replace by well-soldered joints. Joints should not be soldered with "killed salts," but with resin, for if killed salts are used the whole of the joints will, to a certainty, give way by being eaten through in a short time. The perfect success in submarine cable jointing has been only arrived at by a constant supervision over the jointer's work by the electrician, and by every joint in the factory being duly and severely tested, and a record kept of its condition and position. In the same way workmen can only be trained to make electric light joints thoroughly, by the electrician in charge seeing to, and even testing every joint, until he can place implicit confidence in the jointer; in fact, electric light joints have to be better made, if such is possible, as far as metallic contact is concerned. There is no difficulty in soldering a wire capable of carrying 100 amperes or more if done in the proper way.

ELECTRICITY FOR WORKING RAILWAY SIGNALS AND POINTS.—In our leader of last week upon the subject of Mr. Timmis's paper we expressed a desire to hear what conclusion the railway people had arrived at with regard to the experiments recently carried out at Swansea, as one or two electrical engineers connected with railway signalling were dubious about the safety of the system. Mr. Timmis, however, has favoured us with a letter in which he states that the Swansea signal, which has just had a mile of tell-tales and bells, &c., added to it, was merely put up by him commercially; was, in fact, "ordered," "put up," "invoiced," and "paid for." We are pleased to be able to add that Sir Samuel Canning has reported favourably upon the comparative cost of the Currie-Timmis system as against that of the present mechanical system, and sees no reason whatever to differ from Mr. Slater, the manager of the Gloucester Waggon Company, and Messrs. Capper and Schenk, the superintendent and engineer of the Swansea Harbour Trust, as to their high estimate of its efficiency.

VERY LONG DISTANCE TELEPHONY.—We are glad to find that our contemporary, *L'Electricien*, supports us in the view we took of the alleged proposal to experiment with the object of establishing telephonic communication between Brussels and Madrid. Our contemporary says:—Many journals have announced that the Belgian Government were about to enter into negotiations with the French and Spanish Governments in order to obtain the necessary authority to experiment between Brussels and Madrid with a new microphone invented by an officer of the Belgian cavalry. The result of the inquiry we have made has been to show that the report is utterly without foundation; but if it were not so, would it not be demanding of the microphone in question just a *little* more than it could reasonably be expected to perform? Together with the Blake, Berliner, Ader, and other transmitters, it may be adapted to long distance transmission, but *è muito longe de China a Peru*, and, telephonically speaking, so it is from Brussels to Madrid. Unless special lines and special wires are to be constructed, it is difficult to imagine how, with the most perfect of instruments, such a result could be obtained.

SOME APPLICATIONS OF ELECTRICITY.—*The Detection of Heat:* It is often necessary, in scientific investigations and in meteorological observation, as well as in other practical departments, to be able to detect very minute traces or small variations of heat. The thermopile is, as far as we know, the most valuable and practical method, and will detect the heat of a star; but it would not be able to detect the heat developed in a telephone receiving diaphragm, the heat being produced by the mechanical vibrations of the said diaphragm against the opposing electrode; nor would it detect the heat produced in a large wire by the passage of a current from one pair of a thermopile; nor would it detect the heat produced by compression of a piece of metal by another piece of the same weight; nor would it detect the heat or cold of an approaching object with any degree of sensitiveness, the said object being, for instance, a vessel at sea or an iceberg.—*Wanted, an Electric Gas Meter:* Supposing that gas will still be used by sceptics in electric lighting, and that the gas meter will continue to exhibit one's latent faculty for lying, it would not be a useless task to get up a genuine electric gas meter, and then it might be discovered that it could also be employed by electric companies as a gas electric meter. Water gas meters are objectionable, and mechanical gas meters are more so, while an electrical gas meter might be most so; however, its efficiency cannot be predetermined.—*Electrical World.*

THE ELECTRIC LIGHT IN GREENOCK.—An official inspection of the new system of electric lighting which has been introduced by the Police Board of Greenock was made recently in the Water Trust premises at Prospect Hill. The chairman of the Electric Lighting Committee and Corporation officials were present. Professor Jamieson, of the College of Science and Arts, Glasgow, the consulting electrician for the borough, also took part in the inspection. About twenty of the outside lamps were lit, as well as a number of the pilot lamps at the machine room. After thanking the gentlemen for their attendance, the chairman said they would perhaps think the work had taken a long time, but they would agree with him it had come to a successful termination. That success they owed almost entirely to their contractor, Mr. Beckingsale, who had spared neither time nor labour in the work. He had had the advice and assistance of Professor Jamieson, of Glasgow, and their own engineers, Mr. Stewart and Mr. Wilson. Now that the system was started he hoped that the whole community would see that they had done a good work. At all events it showed what could be done in the way of electric lighting. Mr. Beckingsale, in acknowledging the compliment, said that their operations had been greatly retarded during the last three months by the heavy rainfall. Professor Jamieson enumerated the difficulties which had to be overcome

Digitized by Google

in connection with the insulation of cables, and remarked that he would watch the outcome of these operations with interest.

KNOWLEDGE IS POWER.—Some curious tales have been told of telegraphic blunders, and some amusing instances have been quoted of the peculiar ideas entertained by non-technical people as to the nature and capabilities of electricity and electrical apparatus. It is scarcely fair, perhaps, for us to tell tales out of school, but the following anecdotes, as illustrating some of the abstruse speculations into which it is possible for the human mind to enter, are too good to be withheld:—Some time ago at the ——— station of one of the cable companies, an operator who had charge of a Morse circuit, found that something had gone wrong; what, he knew not, but something. He examined the relay; coils still there! The instrument; nothing perceptible! Ink; *that* was all right. Despair! Ha! the batteries. Some hours afterwards the following note was to be seen on the office diary:—"Signals failing; on examining batteries found nearly all the zincs EATEN AWAY BY THE POTS!" The cells were Daniell's with earthenware outer jars. At another station we heard of an individual whose intelligence was almost equally brilliant. There was, it appears, a partial fault in one of the cables, and from time to time the condensers were short-circuited and a powerful copper current put to line for a few moments to seal the fault. X noticed this being done, and his able mind grasped the details in an instant. During the night he short-circuited the condensers, but magnanimously forbore to worry the cable by administering the electrical dose of copper. That being so, it was unreasonable in him to officially criticise the action of the "copper-box" so unkindly. Both these men had been engaged in telegraphy for ten years or so.

ANCIENT TELEPHONY AND PHONOGRAPHY.—The following communication was recently made to a meeting of the Royal Asiatic Society in Shanghai:—"It detracts nothing from the merit of the ingenious physicists who have conferred on mankind the boon of the telephone that its principles are familiar to uncivilized peoples, several of whom are in possession of rudimentary telephones. It was, I opine, when the Chinese were in their youth that they constructed the rudimentary instrument a specimen of which I herewith transmit for the society's museum. It consists of two bamboo cylinders, one and a half to two inches in diameter, and four in length; one end of each is closed by a tympanum of pig bladder, which is perforated for the transmitting string, the string kept in place by being knotted. This rude instrument is styled the 'listening tubes,' and is employed for amusement as a toy, conveying whispers forty or fifty feet. It is unknown in many parts of the empire, Chih-kiang and Kiangsu being the only provinces (so far as I can ascertain) where the listening tube is employed. Besides this toy, Chinese ingenuity produced about a century and a half ago the 'thousand mile speaker.' The implement is described as 'a roll of copper, likened to a fife, containing an artful device; whispered into and immediately closed, the confined message, however long, may be conveyed to any distance; and thus in a battle secret instructions may be conveniently communicated. It is a contrivance of extraordinary merit.' The inventor of the 'thousand mile speaker,' Chiang Shun-hsin, of Huichou, flourished during the reign of Kang-hsi, 17th century. He wrote on occult science, astronomy, &c. The above account of his invention was taken from his works by the author of a Fuhkien Miscellany. At that time—reign of Kien Lung—there was no longer an instrument of this description in that province. It seems to have perished with the ingenious scientist who contrived it."

THE VOLUNTEER TELEGRAPH CORPS.—On the 9th inst. a detachment of fifteen trained telegraphists of the Royal Engineers' Reserve of the Post Office Volunteer Regiment, who are under orders for the Soudan, was paraded at the General Post Office and addressed by the Postmaster-General. Lieutenant-Colonel Taylor; Mr. Algernon Turnor, financial secretary to the Post Office; Mr. C. H. B. Patey; Mr. F. E. Baines, inspector-general of mails; Mr. T. Jeffery, controller circulation department; Mr. H. C. Fischer, controller Central Telegraph Station; and others were with the Postmaster-General. Addressing the men, the Postmaster-General said he was very glad to be able to see them prior to their departure for Suakin, for the purpose of bidding them farewell. Their comrades, who had already gone out to join Lord Wolseley's corps, had behaved themselves in an honourable, a gallant, and an admirable manner, and he trusted that they would do the same in the future. They would be attached to the Royal Engineer Corps, and posted between Suakin and the advanced posts of the Army. He concluded by expressing the hope that they would all enjoy good health and spirits, and return in safety. Lieutenant-Colonel Taylor, on behalf of the detachment, thanked the Postmaster-General. He felt quite certain that the men would do their duty thoroughly well, and he thought he might say that in the Royal Engineers they would have no equals as regards efficiency in telegraphing. He believed that there was hardly a telegraphist left in this country belonging to the Royal Engineers, and without this organisation, which had been encouraged by the Postmaster-General, there would have been grave difficulties in providing for the requirements of the present campaign. He was glad to say that the War Office had sanctioned the extension of the force to 100 men, and that number would, with the necessary permission, be enrolled. The Postmaster-General then addressed the men on the subject of the great heat in the Soudan and the precautions to be adopted against it, and after he had conversed individually with the men the proceedings terminated. Later in the day the detachment left for Aldershot to join the Engineers preparatory to embarkation.

ELECTRIC LIGHTING FOR STEAMSHIPS.—The paper read by Mr. Andrew Jamieson, A.M.I.C.E., &c., before the members of the Institution of Civil Engineers, and of which a digest was given in our issue of 15th November, 1884, has just been published in separate form by the institution. The discussion and correspondence were both of a very interesting nature, Messrs. Farquharson, Allbright, Crompton, and others, affording some valuable items of information as to comparative cost of different systems of lighting and other practical details. Mr. Farquharson said there were but three fighting ships lighted electrically in England. The first lighted by the incandescent system was the Brazilian ironclad "Riachuelo," and since then two other ships in the navy had been fitted, the "Polyphemus," and the "Colossus." A great many transports and troopships had been lighted, and he was able to give some particulars of the results obtained in one or two of them. During the last year and a half five large Indian troopships, the "Malabar," "Crocodile," "Serapis," "Jumna," and "Euphrates," had been lighted, and the Imperial troopship "Orontes." The five large troopships had an installation of about 400 lamps each, and he had some particulars of the cost of two of them, which had been carefully prepared with a view of showing how the cost compared with that of ordinary lighting. Before reading the statement, he might remind the members that it ought not to be assumed that the cost of lighting ships in the Royal Navy by the ordinary system was fairly comparable with the cost of

Digitized by Google

lighting other ships. No mineral oil, for example, was allowed in ships of the Royal Navy, and the colza and olive oil used in them was more costly, so that the comparison would not be the same as that with private ships. The details of the cost of lighting Her Majesty's Indian troopship "Crocodile," for ninety days, by the old and new systems, viz., candles and oil, and electricity by incandescent lamps, was as follows: The number of lamps by each system was about the same. The actual number of incandescent lamps was 438. They were of two sizes—viz., 10 candle-power 307, and 16 candle-power 131. It would seem by the details of cost that the bulk of the ordinary lamps were candles, and the proportion of light would therefore be electrically greater as 10 to 1 or thereabout. Details of expenditure with the new system. Incandescent lamps:—Coal, 112½ tons, at 15s. per ton, £84 17s. 6d.; cotton waste, 90lb., at 27s. per cwt., £1 1s. 8d.; oil (mineral), 180 gallons, at 1s. 2d. per gallon, £10 10s.; oil (olive), 23 gallons, at 3s. per gallon, £3 9s.; lamps replaced, 35 at 3s. 6d. each, £6 2s. 6d.; lamp globes, 15 at 3s. each, £2 5s.; fusible wire plugs, at ¼d., 1s. 8d.; depreciation on plant, at 2½ per cent., £12; total, £119 17s. 4d. By the old system, candles and oil:—Candles (stearine), 250lb. at 32s. 4d. per 50lb., £8 1s. 8d.; candles (police lamps), 1,300lb. at 32s. 4d. per 50lb., £42 0s. 8d.; candles (fighting lamps), 1,750lb. at 34s. per 50lb., £59 10s.; candles (signal), 1,430lb. at 34s. per 50lb., £48 12s.; oil, colza, 493 gallons at 2s. 3d. per gallon, £55 9s. 3d.; wicks, cotton, 160 at 1½d. per dozen, 1s. 10½d.; cotton balls, 8lb. at 8½d. each, 5s. 8d.; chimneys, 4s.; depreciation of plant, at 2½d. per cent., £3 14s.; total, £217 19s. 1½d.; less value of cases returned, £4 14s.; =£213 5s. 1½d.; total cost of new system, £119 17s. 4d.; difference in favour of electricity, £93 7s. 9½d; or £377 per annum. The labour on the two systems was practically the same. The statement took no account of labour by the old or by the new system, the fact being that no additional labour was allowed. Two engine room officers were told off to attend to the dynamos and the incandescent lamps, and since as many lamp-trimmers would be employed on the old system the cost for labour would be approximately the same.

Insulation of Electric Light Leads.—Mr. Sydney F. Walker writes as follows upon the important subject of the effective insulation of electric light leads:—Defective insulation that would be of no consequence with an electromotive force of 50 volts may become a serious matter with 2,000 volts. The minimum insulation resistance allowed on ordinary telegraph wires, consisting of naked iron wire secured to insulators, carried on poles, is 100,000 ohms per mile—that is to say, the resistance of the 20 to 25 branch circuits to earth formed by the insulators, brackets, and poles combined, must not be less than 100,000 ohms in a mile; in half a mile it would be 200,000 ohms; in five miles, 20,000; and in 10 miles, 10,000. Now, with an electromotive force of 50 volts, with lamps run in series, the lowest of these figures means a loss of only $\frac{1}{2000}$ ampere on the way, which would be inappreciable; that is to say, the current arriving at the farthest lamp would be weaker than that setting out from the generator by $\frac{1}{2000}$ ampere, and the work done by this current would be represented by

$$W = E\,C = 50 \times \tfrac{1}{2000} = \tfrac{1}{4} \text{ watt.}$$

With 2,000 volts the case is a little more serious. $\frac{2,000}{10,000} = \frac{1}{5}$ A.

$$\tfrac{1}{5}\text{ A} \times 2{,}000 \text{ v.} = 400 \text{ watts} = \tfrac{1}{2} \text{ h.-p. about.}$$

But suppose the wires have been badly put up, or allowed by neglect to lose their proper insulation, either by having the insulators broken by stone-throwing or the wires improperly fixed to the poles by staples; or led over iron roofs, girders, or otherwise badly laid in any of the numerous ways ignorance can suggest so easily, the resistance might even in a comparatively short time fall to 1,000 ohms.

$$C = \frac{E}{R} = \frac{2{,}000}{1{,}000} = 2 \text{ amperes.}$$

$W = E \times C = 2 \times 2{,}000 = 4{,}000$ watts, representing about 5½ horse-power absolutely wasted, and forming a source of danger. The fires that occurred in the early days of practical electric lighting, which the writer believes were principally, if not entirely, in America, were due to two causes—the use of high tension currents, and neglect of insulation. Wires, between which very great difference of tension existed, were stapled side by side on the same board; sometimes the board got saturated with water or oil, and gradually became a sufficiently good conductor to admit the passage of a small current between the two wires. Carbon was immediately deposited, increasing the conductivity, and at last so much current passed, at some particular spot, that great heat was generated and the wood was ignited. In other cases naked wires with high tension currents in them, were left near together with inflammable substances between, a sudden change in the electrical condition of the circuit gave rise to an *extra* current, which, taking the form of a spark, ignited the inflammable substance between the wires. These are, of course, extreme cases, but they will serve to illustrate both the dangers of electric lighting and the perfect safety of electric lighting currents when proper arrangements are made. The wires on dynamos and the electro-magnets of lamps are simply covered with two coatings of cotton, the great object being to get as much wire as possible into the available space, and each layer close together. It follows, of course, that currents of greater strength than the wires are calculated to carry, char and burn up the cotton covering, rendering the machine or lamp for the time being useless. It will be explained later how this may occur, and how it may be avoided. For leads from dynamos to lamps and back again, naked wires may be used quite safely, supported on ordinary telegraph insulators fixed in the usual way, provided it can be ensured that there shall be no danger of two wires, or two portions of the same wire, coming into contact with each other. Should such an accident occur during the time currents were passing through either of the wires, it would probably result in serious damage to them, and possibly to the machine, if the contact removed much resistance from the circuit. Sparks would pass, burning the wires, and if the electrical conditions of the circuit were sufficiently altered they might be completely fused, unless the engine was stopped in time. It comes, of course, to the same thing, if another conductor, such as a piece of copper wire, be thrown across the two wires. In towns, the writer is very strongly of opinion that no naked wires for electric lighting should be allowed, except in very exceptional cases. Should an electric light wire, in which a current was passing, get into contact with a telephone wire, it might cause a fire in the building where the telephone apparatus was fixed, should some sudden change, as a break in the electric light circuit, take place. Wires covered simply with a plait of cotton or jute have been used, but these are not safe for street work. With low tension currents all would be well so long as the cotton was in the same perfect state as when delivered by the manufacturer; but the cases in which this could be depended on would be rather the exception than the rule. Wet, oil, even a change of temperature might create a condition of things favourable to the passage of a spark between wires lying together, which risk would be, when the tension is high, intensified very much.

THEORY OF MAGNETO AND DYNAMO MACHINES.

XXVI.

The writer of these articles had the misfortune to lose a quantity of manuscript in the autumn of 1883, which contained, among other things, one or two completed articles and much preliminary work into some points of theory not yet elaborated. Recently this has been unexpectedly recovered, and there is therefore no reason why the series should not be completed, although a good deal has happened since the last article appeared on September 29, 1883. Everything hitherto said remains as valid as it was before, and the simplest plan will be to proceed as if no break had occurred.

We can now pass on to consider what happens in a Siemens armature rotating in a uniform field, and making n revolutions per second. Let it consist of $2c$ coils, each of K turns of wire, wound on the drum in pairs—the angle between successive pairs being β or $\frac{\pi}{c}$, just as we considered it in Art. XX. (Nov. 25, 1882); the diagrams of the winding being in Art. XIX.

Let R be the resistance of the armature measured from one segment of the commutator to a diametrically opposite one, or "from brush to brush;" and let L be the self-induction of the armature measured in the same fashion. We will not presume to calculate L, because every coil affects every other as well as itself, and so it is rather complicated; and inasmuch as the drum in practice always contains iron it is not worth while to attempt it; but we will suppose it determined experimentally.

A current entering the armature at one segment and flowing away at a precisely opposite one, will pass through every coil on the armature—c in series and 2 abreast— so that the total resistance is $\frac{c}{2}$ times that of each coil. The current will flow round the constituents of each pair of coils in the same direction; and in fact each pair is virtually but one coil, for, as the amature revolves, reversal takes place simultaneously in both constituents of each pair, as will be seen by referring to the diagram in Art. XIX., two of which it may be useful to reproduce here :—

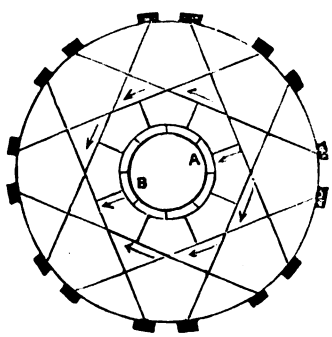

Fig. 10.

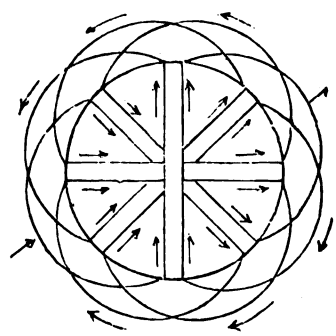

Fig. 11.

They represent the same thing, and taken together they should be intelligible. The outer scallops in Fig. 11 may be treated as the segments of the commutator, and it is then the clearer figure. A B is intended for the line of brushes; and at right angles to this in the diagram is the plane of reversals. Where this plane is with reference to the line of brushes in an actual machine depends on how the commutator is set on the axle, and it is quite arbitrary.

As each pair of coils passes the plane at right angles to A B, during the rotation of the armature, its currents are reversed; hence this is the neutral plane which must be set normal to the lines of force, or rather an angle ϕ in the direction of rotation ahead of this. For observe, that as each pair passes this plane, and has its currents reversed, both constituents are momentarily short circuited, by reason of the two brushes touching adjacent segments of the commutator.

But there are certain curious differences between the present complex machine and the single coil machine or earth inductor discussed in Art. XXV., and these differences must be clearly grasped. In the single coil machine the current taken off by the brushes vanishes twice in a revolution; and accordingly it is possible wholly to avoid sparks by setting the brushes so that the break and reversal may occur at this vanishing position every time. In the multiple coil machine there is no vanishing point at all, the current taken off by the brushes aims at being steady; for only one coil is subjected to short circuiting and reversal at a time—the others are in full work. To wholly interrupt such a current as this, therefore, would entail violent sparking; and, accordingly, it is never to be supposed that the gaps in the commutator are anything like so broad as the brush contacts. To prevent any possibility of a complete break in the circuit it is absolutely necessary that the brush contact shall be broad enough to reach well across from one segment of the commutator to the next; and thus a short circuiting of each coil as its segment passes a brush is ensured, whether it be desirable or not.

But though the main circuit is never broken, it is not possible to set the brushes so that no interruption of current shall occur; for every pair of coils is conveying the whole current, and at the instant when a pair comes up to the plane of reversals, the current *in this coil* is either suddenly reversed or else it is short circuited long enough to allow it nearly to die away, and then the same current is started again, but in the opposite direction. The effect of this process on the main current (*i.e.*, the current in the rest of the circuit) is not very great; it corresponds to a diminution of resistance at the instant when the short circuiting of a pair of coils begins; and an equal gain of resistance, *combined with an increase of self-induction also*, at the instant when the short circuit is over and the coil again enters the main circuit. Sparks at the commutator are therefore, in a multiple coil machine, inevitable, and the only plan is to keep them at a minimum.

The energy lost, as each pair of coils passes the plane of reversal, can be easily expressed. If l represent their self-induction, their current possesses energy, before short circuiting, equal to $\frac{1}{2} l \gamma^2$, and, this having to be destroyed and re-created, the whole loss of energy per pair of coils reversed is $l \gamma^2$; which operation being repeated $2c$ times in a revolution gives a total loss of power equal to $2 n c l \gamma^2$ watts. Half of this loss may go to generate heat in the armature coils over and above the regular heating $\rho \gamma^2$; the other half is necessarily so much energy lost to the main current. The first half may therefore be treated as the heating effect of a sort of spurious extra resistance equal to $n c l$, the second half as a back E.M.F. equal to $n c l \gamma$, which is just the opposing force of the same spurious resistance.

The quantity $c l$ cannot be very different from L, the self-induction of the whole armature, and the coefficient $n c l$ may therefore be written simply n L.

The internal resistance of the armature is not really increased from ρ, its real value, by the motion; because the short circuiting of some of its coils rather lessens than increases its total resistance; but it gets rather more heated than its mere resistance would lead one to expect, the power expended in heating it being $(\rho + n \mathrm{L}) \gamma^2$ watts.

And remember also that at the same time as this extra heat is generated the current is opposed by a back E.M.F., $n \mathrm{L} \gamma$, due to the energy required to re-start the current, and that this is exactly what would be caused by an extra resistance n L; hence, the resultant effect of the successive reversals of the coils is, after all, just to virtually increase the resistance of the rotating armature by this amount n L.

This rather curious result seems to have been originally guessed at by M. Cabanellas; it has been clearly pointed out for the case of a Gramme by Ayrton and Perry, and we believe also by M. Joubert. A rough experimental verification is given by Professors Ayrton and Perry in *The Electrician*, August 18, 1883.

We will obtain the same result in a more general, and perhaps really simpler and more satisfactory, manner before

Digitized by Google

long. Meanwhile here are the numbers given by Ayrton and Perry in their tract on electro-motors (*Journal*, Society Telegraph Engineers, No. 49, Vol. XII., 1883).

	Ohms.
Resistance of Gramme ring, at rest	1,768
,, when turning 10 times a second...	1,828
,, ,, 20 times a second...	1,923
,, ,, 30 times a second...	2,045

The increase in apparent resistance due to the motion is thus not very formidable in amount, but quite distinct.

Taking a measure of the resistance of an armature first still, and then revolving at a known speed in a field of no force, or with its axle along the line of magnetic dip, is the easiest method of arriving experimentally at the value of the self-induction L. The above numbers give, for the particular Gramme ring employed, a mean value of about L = 8 ohm-seconds.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 307.)

Impressed Magnetic Force. Intrinsic Magnetisation.

The energy definition of impressed electric force, due originally, if not explicitly, at least substantially, to Sir W. Thomson, has long been well recognised by most writers on electrical subjects, especially since the practical introduction of dynamo machines, accumulators, &c., which raised the energy transformations concerned in electrical phenomena from being matters of almost purely scientific interest to matters of the extremest practical commercial importance.

But in our last we gave an energy definition of impressed magnetic force, precisely similar to that of impressed electric force. Thus, if h be the impressed magnetic force at a point, and G the magnetic current there, the rate of working is hG per unit volume, and this amount of energy is taken in per second by the electromagnetic system at the place, and is employed in increasing the energy of electric displacement and the magnetic energy, or wasted in the heat of conduction currents. Also it may be used in effecting bodily motions when there is yielding to the mechanical forces, or in chemical work, &c. Should there be no impressed force, electric or magnetic, except an impressed force h in a single unit volume, we have

$$h\mathrm{G} = \Sigma(\mathrm{Q} + \dot{\mathrm{U}} + \dot{\mathrm{T}}),$$

the summation extending through all space where Q is the dissipativity, U the energy of displacement, and T the magnetic energy, all per unit volume. In order to identify the quantity thus defined, and show the relation it bears to the quantity termed intensity of magnetisation, let there be no electric force in the field, and its state be steady. The second equation of induction (23), goes out, since G = 0, and the first (22) is reduced to

$$\mathrm{curl}\,(\mathrm{H} - h) = 0 \quad . \quad . \quad . \quad . \quad . \quad (33)$$

Integrating once, we have

$$\mathrm{H} = h + \mathrm{F}, \text{ where } \mathrm{curl F} = 0, \text{ or, } \mathrm{F} = -\nabla\Omega \quad . \quad (34)$$

Thus the actual magnetic force H differs from the impressed force h by a polar force F, a force which when analysed is found to be made up by the superposition of radial forces proceeding from points. Ω is the potential, a scalar, variable from point to point.

But, so far, there is nothing to settle what particular distribution of polar force F must be. A second condition is wanted. Now we know from equation (23) that the magnetic current, like the electric current, is always in closed tubes, *i.e.*,

$$\mathrm{div.G} = 0, \text{ therefore } \mathrm{div.}\dot{\mathrm{B}} = 0, \quad . \quad . \quad . \quad (35)$$

and if we take the time-integral we find

$$\mathrm{div.B} = f(x,y,z),$$

any scalar function of position, independent of the time. If, then, the magnetic induction B were not also completely solenoidal, its divergence would continue unaltered at any place, however the field might otherwise vary. It could only be altered by convection, shifting the arrangement of matter. It would then, by a suitable arrangement of matter, be possible to have a unipolar magnet, a quantity of matter round which the magnetic force was everywhere directed outward, or everywhere inward. This being contradicted by universal experience, we must conclude that

$$\mathrm{div.B} = 0, \quad \text{as well as} \quad \mathrm{div.G} = 0. \quad . \quad . \quad (36)$$

The second equation of induction (23), if we use the full expression for G there given, is too general, requiring the limitation $g = 0$, from the absence of magnetic conductivity. The now added limitation div.B = 0, as it does not contradict the second equation of induction, must be considered as an auxiliary condition. Though not necessarily dependent upon the first limitation $g = 0$, it is yet intimately connected with it.

Our two equations are therefore (33) and (36), or,

$$\mathrm{curl}\,(\mathrm{H} - h) = 0, \quad \text{and} \quad \mathrm{div.}\mu\mathrm{H} = 0, \quad . \quad . \quad (37)$$

and the question is, given μ the permeability, and h the impressed force, find H the real force. Using (34) we have

$$\mathrm{div.}\,\mu(h + \mathrm{F}) = 0, \quad \mathrm{curl F} = 0, \quad . \quad . \quad . \quad . \quad (38)$$

and, with the same data, we have to find F. By the second of (38), F is restricted to be a polar force; by the first it is still further restricted to have, when multiplied by μ, a given amount of divergence, thus, $\mathrm{div.}\mu\mathrm{F} = -\mathrm{div.}\mu h$. The two conditions together make F perfectly definite, and therefore H and B definite through all space. Of this a variety of proofs may be given (the first was given by Sir W. Thomson in 1848, relating to similar equations, μ being isotropic); the following perhaps puts the matter in as simple a form as it can be put, and is best adapted to the present circumstances.

In the first place there cannot be two solutions of (38) for F. For if (38) are satisfied by F and also by F + f, we have, by subtraction,

$$\mathrm{div.}\mu f = 0, \quad \mathrm{curl}\, f = 0, \quad . \quad . \quad . \quad . \quad (39)$$

as the equations that f must satisfy. But consider the quantity $\Sigma f\mu f$ integrated through all space. It cannot be negative, for every element of it is positive or else zero. Thus

$$f\mu f = \mu_1 f_1^2 + \mu_2 f_2^2 + \mu_3 f_3^2;$$

if μ_1, μ_2, μ_3 be the principal permeabilities, and f_1, f_2, f_3 the corresponding components of f. We suppose the permeability always positive (to deny this would lead to absurdities), hence $f\mu f$ is always positive, or else zero, viz., when $f = 0$. But, by the second of (39), $f = -\nabla p$, if p is the potential of f, and therefore, by a potential property,

$$\Sigma f\mu f = \Sigma . p\, \mathrm{div.}\mu f \quad . \quad . \quad . \quad . \quad . \quad (40)$$

and therefore vanishes, by the first of (39). Hence $f = 0$, making the supposed two solutions identical.

Next, to show that there is one solution, consider $\Sigma\mathrm{H}\mu\mathrm{H}$ through all space. This is also positive, or zero, whatever H may be, by the same reasoning, so has necessarily a minimum value. If H be quite arbitrary, the minimum is zero, when H = 0 everywhere. But H = h + F, and here h is constant. Let F vary. The corresponding variation in $\Sigma\mathrm{H}\mu\mathrm{H}$ is

$$\delta\Sigma\mathrm{H}\mu\mathrm{H} = \Sigma\delta\mathrm{F}\mu(h + \mathrm{F}) + \Sigma(h + \mathrm{F})\delta\mu\mathrm{F} = 2\Sigma\delta\mathrm{F}\mu(h + \mathrm{F}). \quad (41)$$

Now subject F to either of the two equations (38), say the second, so that $\mathrm{F} = -\nabla\Omega$. Thus, similarly to (40),

$$\delta\Sigma\mathrm{H}\mu\mathrm{H} = 2\Sigma\delta\Omega\,\mathrm{div.}\mu(h + \mathrm{F}). \quad . \quad . \quad . \quad (42)$$

Hence, to make $\Sigma\mathrm{H}\mu\mathrm{H}$ a minimum requires $\mathrm{div.}\mu(h + \mathrm{F}) = 0$, which is the first equation (38). Thus, when F satisfies both equations, it makes $\Sigma\mathrm{H}\mu\mathrm{H}$ a minimum. But this quantity *has* a minimum, therefore there *is* a solution of the equations (38), or F is a definite vector for every point of space.

If we assume that μ contains a rotatory vector ϵ, so that

$$\left.\begin{aligned} \mu\mathrm{H} &= \mu_0\mathrm{H} + \mathrm{V}\epsilon\mathrm{H} \\ \text{let} \quad \mu'\mathrm{H} &= \mu_0\mathrm{H} - \mathrm{V}\epsilon\mathrm{H} \end{aligned}\right\}, \quad . \quad . \quad . \quad . \quad (43)$$

then μ' is conjugate to μ, and $\frac{1}{2}(\mu + \mu')\mathrm{H} = \mu_0\mathrm{H}$, where μ_0 is self-conjugate or non-rotatory. Instead of (41) we shall have

$$\delta\Sigma\mathrm{H}\mu\mathrm{H} = 2\Sigma\delta\mathrm{F}\mu_0(h + \mathrm{F}), \quad . \quad . \quad . \quad . \quad (44)$$

and the minimum is given by $\mathrm{div.}\mu_0(h + \mathrm{F}) = 0$, which is not the proper condition.

Digitized by Google

There is a similar failure in the mathematically analogous problem of conduction current kept up by impressed electric force, when the conductivity k is rotatory.

In connection with the above, we may notice two special solutions of (37). First, if curl $h=0$, then curl $H=0$, which, with div.$\mu H=0$, requires $H=0$, and therefore $B=0$. That is, if the impressed force be wholly polar, there is no induction. The simplest example is a closed magnetic shell of uniform strength, and any thickness, an assemblage of magnets put together side by side in such a manner that there is no induction anywhere.

Secondly, if div.$\mu h=0$, then div.$\mu F=0$, which, with curl $F=0$, requires $F=0$, therefore $H=h$, and $B=\mu h$. Here the impressed force everywhere produces the full induction, and there is no polar force.

Comparing our equations with those occuring in the problem of magnetisation, we find that, if I be the intensity of intrinsic magnetisation, it is related to h, thus

$$I=\mu h/4\pi \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (45)$$

h may therefore be called the intrinsic magnetic force, if we like. The real magnetisation is the sum of the intrinsic and the "induced," which we shall call i, and the ordinary form of the magnetic induction equation is

$$B=F+4\pi(I+i), \quad . \quad . \quad . \quad . \quad . \quad . \quad (46)$$

where F is the polar force due to both the intrinsic and the induced magnetisation. It is the same as F above. And to identify (46) with the equation $B=\mu H$ we use always, we have first

$$i=\kappa F,$$

giving the induced magnetisation in terms of the polar force, κ being the coefficient of induced magnetisation, next the equation (45), and lastly, $\mu=1+4\pi\kappa$; so that (46) becomes

$$B=F+\mu h+4\pi\kappa F=\mu(h+F)=\mu H \quad . \quad . \quad (47)$$

It will be seen that this separation of magnetisation into intrinsic and induced is a roundabout way of treating the subject, and that there is considerable simplification obtained by always using the equation $B=\mu H$, both in an intrinsic magnet and without it, ever employing the two ideas of magnetic force and magnetic induction, and letting magnetisations alone. The quantity B is the magnetic induction as ordinarily understood, H is also the magnetic force as ordinarily understood everywhere, except where there is intrinsic magnetisation. There, however, we add the intrinsic or impressed force h, making $H=h+F$ in general, just as in a conduction current system we add the impressed force where there is any to the polar electric force and that of induction to obtain the resultant efficient electric force. H is thus always the resultant magnetic force from all causes, and although in the above we have considered no electric currents to exist, yet we may add that should there be any, H will be equal to $h+F+F_1$, where F_1 is the magnetic force of the current; and $B=\mu H$ always.

The term "intrinsic," as applied to magnetisation, is used by Sir W. Thomson, but not by Maxwell, though he gives the same theory of induced magnetisation as the former. It is not always clear in Maxwell's treatise whether by magnetisation he refers to the intrinsic only or to the actual, including the induced. Maxwell's equations of disturbances also break down when they are applied to the interior of an intrinsic magnet, owing to his use of the equation curl $H=4\pi\Gamma$, as the relation between the magnetic force and the current, whereas it must be (equation (32)) curl $(H-h)=4\pi\Gamma$, where there is intrinsic magnetisation, if we are to obtain consistent results.

Although in identifying I with $\mu h/4\pi$ we have, by means of the two equations of induction (32) and (33) and the equation of energy deduced therefrom, obtained a justification of the energy definition of h, similar to that for impressed electric force, yet as the consequences are of some importance in variable states, they may be advantageously followed up from the impressed force point of view.

Magnetic Energy. Double work of Magnet.

Let there be a distribution of impressed magnetic force h in a medium of given variable permeability μ—for example, a magnet in air containing soft iron and any other substances. Imagine the impressed forces to be put on suddenly. We know, by the above, that a certain definite distribution of magnetic induction is set up, which is steady when the arrangement of matter is fixed. During the transient state there is magnetic current everywhere unless $\mu=0$ somewhere, which we must believe to be impossible, since μ is very little less than unity for any known substance. The magnetic currents are wholly closed. They are accompanied by electric currents, also closed, in all space, in general. When they have ceased, there is no electric force anywhere, and the magnetic induction at any point is the time-integral of the magnetic current $\times 4\pi$. Compare the work done by the impressed forces with that done by the actual forces through all space. The latter is, per unit volume,

$$\int HG\,dt=\int H\mu\dot{H}/4\pi.dt=\int\frac{d}{dt}(H\mu H/8\pi)dt=H\mu H/8\pi.$$

where in the last expression H is the final value of the magnetic force. In the integrals, H is the variable value at time t. Let T be the whole work thus done in all space, then

$$T=\Sigma H\mu H/8\pi. \quad . \quad . \quad . \quad . \quad . \quad . \quad (48)$$

On the other hand, the work done by the impressed force per unit volume is

$$\int hG\,dt=\int h\mu\dot{H}/4\pi.dt=h\mu H/4\pi\ ;$$

so, if T_1 is the whole work done by the impressed forces,

$$T_1=\Sigma h\mu H/4\pi, \quad . \quad . \quad . \quad . \quad . \quad . \quad (49)$$

where the summation may also extend through all space, since where there is no h nothing is contributed to the sum. Now $H=h+F$, and

$$\Sigma F\mu H=\Sigma\Omega\text{div}\mu H=0, \quad . \quad . \quad . \quad . \quad (50)$$

because F is polar and μH solenoidal. (Similar to (40).) So in (49) we may add F to h, making

$$T_1=\Sigma(h+F)\mu H/4\pi=\Sigma H\mu H/4\pi=2T, \quad . \quad . \quad (51)$$

by (48). The impressed forces therefore do double the work of the actual magnetic forces during the transient state. The excess is done by the electric forces. For, integrating (28), to the time, with $e=0$, and also through all space, to get rid of W,

$$\Sigma\int hG\,dt=\Sigma\int E\Gamma dt+\Sigma\int HG\,dt;$$

and, since finally $U=0$, we have

$$T_1=\int Q\,dt+T. \quad . \quad . \quad . \quad . \quad . \quad . \quad (52)$$

Hence, by (51), $T=\int Q\,dt$, the total heat in conductors arising from induced currents.

One half the work done by the impressed forces is wasted in heat of induced currents, the other half is the magnetic energy set up, expressed by (48). Now, suddenly remove the impressed forces; there will be a similar inverse transient state, during which, as the magnetic induction subsides, the whole of the energy T will find its way to the conducting parts to be there wasted as heat. The intrinsic magnet itself, it should be remembered, would come in for a large share of this; in general, or, in special cases, the whole. T is thus the whole amount of work that can be got out of the magnetic system by removing the intrinsic forces, which is why we term it the magnetic energy.

It may be objected that the above is unrealisable, that we cannot put on, or suddenly remove, the retentiveness of a magnet, and so obtain the whole magnetic energy existing in a given configuration in work. Admitting this, it may be remarked that we can do something equivalent, or at least approximate thereto, in the following manner. By means of a properly chosen distribution of impressed electric force we may set up electric current that shall exactly neutralise the field of the magnet, producing a state of no induction. Now suddenly cut off the impressed electric forces that kept up the currents. We then start with no induction, and terminate with the proper distribution of induction due to the magnet, and the impressed electric forces do no work, being cut out. Hence the effect is the same as suddenly putting on the impressed magnetic

Digitized by Google

forces, doing 2 T of work, one half magnetically, the other half being expended in the heat of induced currents. Some simple examples to illustrate this will be worked out later.

This extreme case will serve to illustrate the meaning of the distinction between the work done by h and by H, also the meaning to be attached to magnetic energy. There are other ways of course of using up the energy T above said to be wasted in heat. Thus, if we alter the configuration of the matter in our magnetic system, we usually alter T. Let it be increased from F to F + δF. Thus the impressed forces h will do 2δF of work, one half magnetically, in increasing F, the other half mechanically, by the mutual stresses assisting the motion, and this latter half will be partly wasted in heat at once by the induced current accompanying the motion, and all may be ultimately thus wasted.

This naturally brings us to the subject of the mechanical forces.

(TO BE CONTINUED.)

CORRESPONDENCE.

THE WIMSHURST ELECTRICAL INFLUENCE MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In two lectures recently delivered by Professor J. Lodge at the London Institution on "The Nature of Electricity," it was often said, he remarked, that we did not know what electricity was; and Professor Tyndall, in a recent lecture on "The Sources of Electricity," stated that it would take him some time to go through the philosophy of the above machine, nor was he sure that he could do so; but I think that by capitalising the facts associated with electricity and the *influence* machine, we shall be not only able to show that our ignorance of electricity is not so great as some would make it appear, but also to solve the principles which govern the action of the machine.

It is a well established fact that if a metal in solution be subjected to the influence of electricity it may not only be precipitated on another metal, as in the process of electroplating, but is also made to firmly adhere to the metal, thus affording evidence of there being in the current the "forces" of attraction and of cohesion, and I need scarcely state that it has the property of crystallising.

If a quantity of a salt be put into a pan and subjected to heat, the salt is decrystallised and dissolved; and if that hot solution be placed on straw, or other insulating medium, in a dark corner, out of doors, during a hard frosty night, when the thermometer is considerably below the freezing point, flashes of light may be seen to go to the pan, and the salt crystallises. Here, then, we have evidence that what we call heat has a disentegrating influence, whilst cold has the property of combining.

Neither ordinary cold nor heat will travel along a wire, if even the wire be connected with a hot body or a lump of ice; but if that ice be mixed with salt, and the combining agent in both the salt and ice be set free, as in the freezing mixture, the *intense* cold will find its way to a hot solution through a very fine copper wire, some 12ft. long, and cause the crystallisation of salt; and I have not the slightest doubt but that a similar result might be obtained by connecting a solution with an internal wall of a building during hard frosty weather. I know that a solution of alum so connected, when a summer sun was shining in full on the exterior of the house, was retarded in its crystallisation, and hastened when the same wall was influenced by a heavy shower.

Facts of the above nature, all tending to the same conclusion of the relation of heat and cold to electricity, may be adduced by the dozen; and if air be subjected to the influence of compression, and turned into a chamber where meat is suspended, the meat is not only frozen but may be kept in the frozen state during its transit from the Antipodes. If, however, instead of its being set free, the air be compressed into a tank or iron vessel, having a nozzle at an angle of 45°, on the valve being turned the escaping air will send an india rubber ball spinning in the direction of the jet. The ball takes the oblate spheroid form, then collapses, still spinning on its centres, and if the valve be partially closed, the ball, instead of falling, actually returns to the nozzle, thus affording conclusive evidence that, associated with the foregoing influence of compressed air, there is in it a "force" that overcomes gravitation.

It will no doubt be within the remembrance of my readers of mature age that in 1845 there was at the Polytechnic Institution an "electrical boiler" of gigantic electrical powers. After a number of sittings of observation, I solicited of and obtained from the directors permission to make certain experiments, and in my application I observed that the electricity on going to the boiler, &c. But on my arrival I was told by Professor Bachoffner that the electricity did not go to the boiler at all, but only from it with the steam, an error of which I convinced him by presenting my head to the machine when in full action, and sending from it three flashes of electricity at least 6in. long.

At that time (1845) I thought the electricity was blended with the steam, but having at a later period conceived the law that all heated or incandescent bodies, such as a burning taper, fire, or redhot piece of iron, are surrounded by an atmosphere electrical in proportion to the incandescence, and a close inspection of an oak that had been struck by lightning, I came to the conclusion that it was the outside of the boiler that became electrical, and that the electricity blended with the negative steam in its escape. But whilst I must allow that the question is open to consideration, which it assuredly should have without loss of time, I can unconditionally aver that compression, under all circumstances, induces electricity; and if the matter compressed be of a cohesive or sticky nature, such as hops, meal, or wood, it actually increases in weight. This increase of weight by compression I deduced, in 1848, when writing a paper for the then Board of Health, and which paper was first printed in *Newton's London Journal*. That matter in gravitation is repelled by the surrounding regions in proportion to its electrical condition, and therefore must increase in weight in proportion to the quantity of electricity acquired by the compressing influence.

About the close of the year 1880, there appeared an article in the *Engineer* respecting the Reese fusing disc, which consists of a thin disc of soft steal that is made to revolve with great velocity. If there be placed in front of it a round bar of cast steel, it will cut that bar in two in the same way as a soft iron disc cuts up old steel railway rails—that is, by detaching particles of the metal, which particles, by combining with the oxygen of the air, produce sparks. But if, on the contrary, the round bar of cast steel be made to revolve at a much less rate than the soft steel disc, the disc, without touching the bar, actually makes its way through it, the steel of the bar so turned out being converted into a mass of the consistence of putty or butter.

This fact was necessarily declared to be opposed to all preconceived notions, but, as I observed at the time, allowing that centrifugal force should produce electricity, evidently that of the round bar would be of much less tension than that of the disc; and if the latter, being directed on a small part only of the bar, should cause the electricity of the bar to flow to that spot, the concentrated influence would necessarily induce a negative state in the bar in front of the disc, to the withdrawal of the bond of union, and production of the butter of steel.

In the days of the imponderables, heat, light, and electricity, the first was the all-pervading agent, and the other two effects only; but some time about or before 1830 there appeared a very long correspondence between two of our then greatest authorities—one in London and other on the other side of the Atlantic—on the nature of heat, and as that discussion terminated in neither being convinced, it produced in me the consideration whether the subject itself must not be at fault; and by compiling a host of facts, but carefully excluding the opinion of our authorities, I obtained conclusive evidence that heat was nothing more than an effect; that, in fact, it was the absence of cold.

Digitized by Google

It was, however, some fifteen years later, at the close of an inquiry on the general properties of matter, that the magnitude of my subject became apparent, and in 1845 I produced my first paper in the *Mechanics' Magazine* on the Constitution of Snow, and other such questions, in all of which electricity was an agent and not merely an effect; and this was followed by a series of papers in the *Chemist* from April to October, inclusive (1847), on various subjects connected with electricity. Now, however, by the accompanying extracts everything is to become electricity.

"Mr. T. A. Edison, of Menlo Park, New York, has always been rather conspicuous for the speculative boldness of his ideas, and if he had not actually done some very marvellous inventive feats he might be regarded—or disregarded—as a mere dreamer of dreams. Too many of his dreams have been fulfilled, however, to permit of his being deemed unworthy of the most serious attention, however apparently wild may be his scientific forecasts. He has just given, in the New York *Tribune*, expression to one which certainly looks to be very wild indeed. As everybody knows, an enormous amount of capital and ingenuity has been devoted to the creation and perfection of machinery for the generation of electricity. Mr. Edison now ventures on the prediction that many now living will probably see the time when all this machinery will be unnecessary, and when electrical energy will be derived directly from coal, which is stored up solar heat and light. The notion of certain French and German scientists, that solar light and heat may by and by be tranformed directly into electricity, the New York prophet scouts as mere wild chimera, or at any rate as something too remote and untrustworthy to be within the limits of practical science; but that the transformation will before very long be effected directly from the coal he believes to be a 'certain fact.'"

I can assure Mr. Edison that our coal beds were laid down in the absence of sun, and that the heat and light we get from coal proceed from chemico-electrical action.—Yours, &c.,

ELECTRICAL CONDITION OF 1848.

20th February, 1885.

ELECTRICAL UNITS, &c.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think we ought all to thank your correspondent, Mr. Swinburne, for his outspoken remarks upon the present hopeless confusion in our standards of measurement. It appears to have occurred to him, as it no doubt has or soon will occur to others, that when examining at least the units of electricity and light it is not only expedient but absolutely necessary to lay aside coloured spectacles.

There is one factor of paramount importance in every calculation—and specially affecting physical science—which ought to be, and is supposed to be, absolutely fixed and accurately determined. That factor is mass. The slightest error regarding it involves everything connected with it, and leads to an unceasing attempt to invent new definitions (?) and hypotheses for the purpose of avoiding the difficulties to which that error leads, and hiding, under an apparently transcendental perfection, an imperfection which only those who dare to lay aside spectacles fully realise.

I have for over twenty years past been examining that factor and its relation to weight. I wrote fifteen months ago to an eminent authority, respectfully stating that mass did not always vary directly as weight, and that only those who never dare to face facts could now conclude that it did. The reply I got was, "calculation goes to show that it must, and experiment agrees with such calculation."

I allowed twelve months to pass and wrote the same authority again, stating that with the most careful procedure, and after taking precautions beyond those of Cavendish and Baily (whose experiments incidentally bear well upon this question), I found mass did not vary directly as weight experimentally. Mark the difference of the reply. Its effect is this: "There is no *à priori* reason for saying that mass varies directly as weight, it simply depends upon two experiments, one 200 years old, the other made in 1826."

How gratifying it must be to know that the whole scientific edifice is supported by two (!) experimenters' results. If experiments were necessary at all, why not more? If the proposition was self-evidently true, why make any experiments at all?

Faraday was wiser than his feeble imitators when he concluded the chemical atoms were "centres of force."

My experiments prove that mass must be taken out of all our formulæ, and written down as energy. If it is asked what is to become of all the imposing terms, equations, and proofs of our mathematicians and speculators, I reply they must and will accommodate themselves to fact. No one who knows their enormous modulus of elasticity can doubt their ability to do so when they are made.

The change may be made now or deferred, as your correspondent says, till doomsday; but the latter alternative will only perpetuate what he well terms patchwork, and hold out inducements to those he refers to and their *clientèle* to postpone their retirement to the congenial shades he indicates, where, if they had gone long since, with the whole stock in trade of coloured spectacles and without return tickets, we should have had less reason to say to-day what true men of science all over the world feel, viz., that there is something rotten in the state of Denmark.—Yours, &c.,

W. H. SHARP.

18, Gertrude-road, Anfield, near Liverpool.

INCANDESCENT LAMPS AND THEIR HOLDERS.

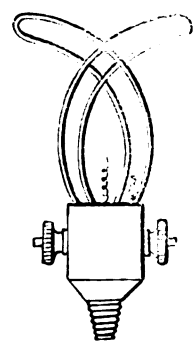
TO THE EDITOR OF THE ELECTRICIAN.

SIR: If I am not trespassing too much upon your valuable space, perhaps our experience in this matter may be interesting.

We have never departed from the original plan of loops at the bottom of the lamp; and up till very recently we could find no better form of holder than the old Swan, with the large spiral clasping the neck of the lamp.

The loops of many of the earlier lamps were often exceedingly troublesome. Now one would break a loop off close to the glass, and another time the loop or the hook would fuse. But as the manufacture improved, and the men who had to change the lamps became more accustomed to the work, and more handy with their fingers, these difficulties gradually disappeared.

It was rather difficult to hook on a lamp to the old Swan holder in the dark, as I have had to do underground in a colliery, or with only the dim light of a miner's lamp, but with the cross holder which we have now been using for some



time we have very little trouble, as the connections are not hidden by the sprays, and they are easily hooked to the loops, no matter how erratic the latter may be. One thing we discovered rather early, wherever there is much vibration a rigid holder soon shakes out of contact, and is therefore useless.

I think that the loop form carefully made, with platinums rather stronger and a holder something after the style of the sketch enclosed, should fulfil all requirements.

Mr. Cox-Walker's holder, like everything issued by his firm, has evidently been very carefully worked out and is well made. Time will show if it possesses sufficient advantages to warrant the extra cost over other forms.—Yours, &c.,

SYDNEY F. WALKER.

195, Severn-road, Cardiff, March 10, 1885.

A PERSONAL EXPLANATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am informed that the expression "Mr. Wright, one of the members of our class," in Professors Ayrton and Perry's paper, read at the Physical Society, and published in your last issue, conveys, though doubtless quite unintentionally, the idea that the result communicated to you in my letter of the 12th ult. was obtained from Professor Ayrton's lectures, which I have been attending (I have never attended any of Professor Perry's).

I therefore ask you to allow me to state the facts. Professor Ayrton pointed out in one of his lectures the importance of establishing the relation between the life of incandescent lamps and the volts used; but he recommended to try for a rectangular hyperbola, nor has he even once mentioned the logarithmic relation, which I communicated to you, or any resembling it. My letter was in the printer's hands on Thursday, the 12th ult. On Monday, the 16th, I told Professor Ayrton that I had found the required equation, which he thereupon took down in his study from my dictation, and we spent some time in adapting it to the lamps at the college.

The next day Professor Ayrton informed me that the matter had been worked out by Professor Perry two or three days before.

Finally, I am glad to say that when I told Professor Ayrton that I had sent the working to *The Electrician*, he replied, "Certainly, certainly," with emphatic approval.—Yours, &c.,

F. M. WRIGHT, M.A. (Oxon),
Assistant Teacher of Mathematics,
March 9th, 1885. Finsbury Technical College.

THE COX-WALKER LAMPHOLDER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your kind notice of the above in last week's issue, will you allow me to say with reference to your suggestion as to the possibility of any shadow from the supporting wire, that in order to make this entirely imperceptible I have reduced the thickness of the wire to a mere line; and also I must remind you that this support may be *dispensed with altogether*. The fittings may be nickel plated, and the nipping plates platinised; but the latter process would add to the cost.—Yours, &c., E. COX-WALKER.

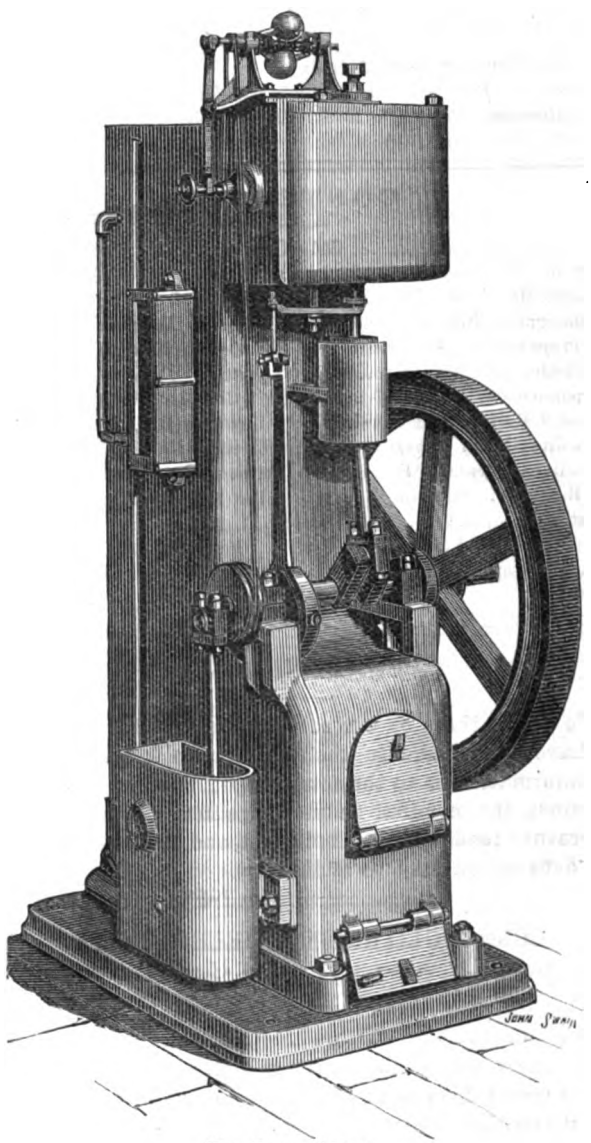
Darlington, March 9, 1885.

THE DAVEY MOTOR.

The Davey small-power motor, shown by the accompanying illustration, is being used for electric lighting, it being found that, with a good dynamo, nine incandescent lamps may be supplied with current for each indicated horse-power. The engine was originally intended for powers of from half to two horses, but is now made up to 4 horse-power indicated. It is double-acting, being supplied with steam at or just below atmospheric pressure, subsequently condensed. About a gallon of water per horse-power per hour only is required; and it can be used over and over again by employing a small tank. Careful experiments have shown the consumption of gas coke to be 8lb., costing about a farthing per indicated horse-power per hour.

In external form, the engine somewhat resembles a single-standard steam-hammer, the cast-iron boiler forming the frame. The fire-box and up-take, cast in one piece, are placed inside the boiler, being connected therewith by cement joints, caulked into the sockets left to receive them in the top and bottom of the shell, the fire-hole joint being made by a ring, coated with red-lead cement, driven in tight. A projection in the upper part of the boiler receives the gun-metal cylinder, which is thus continually surrounded by steam. An ordinary slide-valve, without any valve-chest, admits the steam to the top and bottom of the cylinder, while a stop-valve serves for starting and stopping. For electric lighting, a high-speed governor is added for securing a constant speed. The piston-rod, working in a cylindrical guide, actuates the connecting rod and crank shaft in the usual manner, the bearings being cast in one with the boiler. The crank-shaft carries an eccentric for working the slide-valve, a disc crank for the air-pump rod, and a fly-wheel which serves as pulley for driving. The fire-hole and ash-pan doors are seen in front, below that part of the boiler which does duty for bed-plate. The plunger of the single-acting air-pump is not packed; when near the bottom of its stroke, it uncovers a small hole, which allows water from the hot well to fall back into the plunger and over its edges, thus forming a water seal.

The boiler is fed from a closed feed-chamber, cast on the side of the condenser above the hot well. This chamber is in free communication with the boiler by two passages leading, the large one into the steam space, and the small one to the boiler below the water line, so that the water in the feed-chamber stands at the same level as in the boiler. The feed-chamber is supplied with water by a pipe with cock, having a nozzle which projects into the chamber, the nozzle being fitted with a plug and float. The float falls with the water, thus admitting more water until the proper level is restored. To start the engine, steam is got up until it blows through a loose cover at the top of the boiler, thus expelling the air; and on the engine being turned round, thus blowing through the condenser, a partial vacuum is formed, the motor working like an ordinary condensing engine. It is, however, found to work best when



The Davey Motor.

steam is kept just below the blowing off point, or practically at atmospheric pressure, as, in that case, air does not enter at the piston-rod and valve-spindle stuffing boxes; it will, however, work with several inches of vacuum in the boiler.

The vacuum obtained in the condenser is 25 to 26in., and an experiment was made to show the degree of vacuum required to overcome the friction of the engine and resistance of the air-pump, with the result that, with a condenser vacuum only 5in. of mercury lower than the boiler pressure, the engine ran at its normal speed. As, under ordinary working conditions, the difference between the boiler and condenser pressures is about 25in. of mercury, there is an available margin of 20in. of mercury, or say 10lb. per square inch above that required to overcome the friction of the engine. This shows an efficiency of 80 per cent., not a bad result; and, working at atmospheric pressure, the Davey motor is no more liable to burst than a tea-kettle, while, as the boiler is self-feeding and the fire can be made up to last for a long time, the least possible attention is required.

CONDENSERS.

We invite those of our readers who are Electricians and who have Condensers in their charge to kindly furnish us with information as to the actual capacity of such Condensers as against the nominal value; together with a note of the temperature readings with both wet and dry bulbs; and any other data which may be of interest.

COSMOPOLITANISM IN ELECTRICITY.

In a few days the International Society of Electricians, whose headquarters are at Paris, is to justify its existence. This society is an outcome of the Electrical Exhibition of 1881. The electrical world then met at Paris, and, among other things, succeeded in discussing the question of units. It was felt that isolation in matters scientific was far from beneficial, and it was hoped that an international society would find work to do of a general character. There is plenty of work—the only question is, what class of work should be left to a cosmopolitan society? Next week the members of the society and those who are favoured with invitations and can go to Paris, will have provided for their edification an exhibition consisting of some hundred and forty or hundred and fifty exhibits, in addition to a series of papers to be read and discussed day by day by some of the most eminent scientific men of France. It may not be too late to alter the programme, and, if not, it might be suggested that a clear and distinct individuality be given to the society. We do not want to hear the ordinary run of papers usually read at electrical conferences; nor do we want papers containing the history and results of original research. The various "learned" societies provide an outcome for pabulum of this kind, while they have not sufficient power to determine other matters. Some years ago it was suggested to our own Society of Telegraph Engineers that it should form a committee to investigate and authoritatively decide, so far as Great Britain was concerned, questions of notation and nomenclature. A paper on this subject is just now before the society for discussion. We are necessarily writing before the ordinary meeting of the society, when the paper is to be read by one of the members of the society. Such a paper carries absolutely no weight. It is a record of individual opinion, and nothing more. The suggestions made in the paper may be adopted or may be rejected at the whim of any writer. The case would be vastly different if the society itself issued an authoritative notation, which should be made compulsory in papers submitted for reading and insertion in its journal. We could guarantee that if a notation was thus authorised, one authorised after due consideration, and recommended by a sufficiently strong and dispassionate committee, the technical press—so far, indeed, as regards that portion of it commanding or compelling respect—would accept with thankfulness the notation. A step further takes us to the International Society, and one of its objects we maintain should be to secure a universal notation and nomenclature for the use of electrical students. Pure science is having under its auspices an innings for the strict definition and determination of "units." While admitting the great desirability of settling the question of "units" once and for all, we see little prospect of such a settlement. The existing race of scientific men act and talk as if they had arrived at finality. Why, next year or next week may produce a discovery that would necessitate the modification of what has been or is to be strictly settled. Practical men are beginning to kick at the constant ringing of the changes, and who can blame them? It is altogether different with questions of "notation." A universal system might easily be adopted without interfering in any way with national or personal prejudices. Such a universal system would be very valuable to students, to writers, and to readers. We know of one small English society, formed in the interests of a particular application of mathematical knowledge, which has recognised the want of a systematic notation, which has discussed and decided upon the notation, and has seen its work adopted throughout the civilised world. Most of our readers know that this question of notation is one that we have from time to time discussed for many years past, and if we urge the members of the International Society, or the members of the Society of Telegraphic Engineers, to make common cause in getting a system adopted, it is because we believe an authoritative settlement would be beneficial in all directions.

Other important questions might be suggested for the consideration of the cosmopolitan—such as the one for which we have asked the co-operation of readers, viz., the changes which take place in "condensers." Valuable work would be done by those who have charge of condensers if they would write a daily history of the apparatus in their charge. Then we have the changes which take place in the wire, &c., subject to electrical use. But it is sufficient to throw out a suggestion, and not necessary to follow it into all its details.

In conclusion, we may say that the meeting of the society will last for seven or eight days, and be held at the Paris Observatory. The Exhibition will be opened daily from one to five and from eight to eleven. There will be one or two conferences each evening in a special room. The meeting of the society was fixed for the 15th inst; but at the moment of going to press we have been informed by telegraph that the

Digitized by Google

opening of the Exhibition and Conference will be delayed for eight days. This delay will permit of some modification of the programme in the direction we have indicated, if it should be found that such modification would meet with general approval.

ALTERNATING CURRENTS.

BY THOMAS H. BLAKESLEY, M.A., M. INST. C.E.

(CONTINUED FROM PAGE 327.)

Before discussing some of the effects upon the practical applications of electricity of coefficients of mutual and self-induction, it will be well to consider the action of a condenser whose plates are joined to different points of a circuit conveying an alternating current, for we shall find that in cases where both capacity and coefficients of induction exist, they are capable not only of modifying the effects of each other, but of masking the effects of resistance. It may even be possible by suitable adjustment of the quantities concerned to put through a resistance which is not closed a current of the same amount which would flow through it if it were closed, but denuded of the condensing apparatus and induction coefficient.

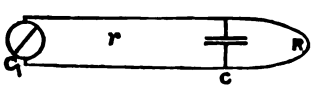

FIG. 6.

In Fig. 6 suppose that G is a source of harmonically varying electromotive force, working into a circuit whose total resistance is $\overline{R+r}$, and that at C there is a condenser of capacity C connected with the circuit in such a way that the section of the circuit terminated by the plates of the condenser and containing the source G has a resistance r, and that the remote section has a resistance R. We shall also suppose that there is no self-induction in either section of the conductor. Take a straight line, O C, on any convenient scale to represent

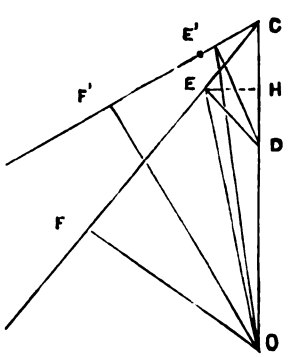

FIG. 7.

the electromotive force of the source, and divide O C in D so that O D : D C :: r : R.

Calculate the quantity $\frac{C\pi Rr}{T(R+r)}$, where T is half the period.

From the nature of the units involved this quantity is necessarily positive and numerical, and it may therefore be represented by the tangent of an angle in a diagram where the lines, as in the case before us, are electromotive forces.

Set off the angle O C E of such a value that its tangent has this value, and in the direction of retardation. From D draw D E perpendicular to C E, and join E O. Then O E and E C will represent in phase and magnitude the effective electromotive forces in the two sections. That is to say, the current generated in r will be that due to an E.M.F. of the value O E operating upon a simple circuit of resistance r, and the current generated in R will be that due to an E.M.F. of the value E C operating upon a simple circuit of resistance R. To prove this, produce C E to F, and draw O F perpendicular to C F.

In the first place it is to be observed that the difference of potential of the plates of the condenser constitutes the effective electromotive force in the circuit R. Also the difference between the generated E.M.F. and that due to the plates of the condenser constitutes the effective E.M.F. in the circuit r.

But the generated E.M.F. is O C. If, therefore, E C does represent the E.M.F. due to the condenser—*i.e.*, the effective E.M.F. in section R—it follows that O E will represent the effective E.M.F. in section r. Thus the two points to be proved stand or fall together, and we may prove the proposition by a *reductio ad absurdum*.

Thus, if E C is not the effective E.M.F. in circuit R, let E′ C be the value in phase and magnitude. Join E′ O, E′ D, and draw O F′ parallel to O E′.

Now, because E′ C represents the effective E.M.F. in R, therefore O E′ represents the effective E.M.F. in r.

Therefore $\frac{E'C}{R}$ is the effective current in R,

and $\frac{OE'}{r}$ is the effective current in r;

but F′ E′ : E′ C :: O D : D C, because O F′ is parallel to D E′.

Therefore F′ E′ : E′ C :: r : R,

and hence $\frac{F'E'}{r}=\frac{E'C}{R}$.

Therefore $\frac{F'E'}{r}$ is the effective current in R,

and since $\frac{OE'}{r}$ is the effective current in r, therefore the currents $\frac{OE'}{r}$ and $\frac{EF'}{r}$ are those currents considered as conveying electricity *into* the condenser, the positive current in r being of course a negative current as regards charging the condenser. But these are the only two currents affecting the condenser; therefore $\frac{OF'}{r}$ is the effective charging current of the condenser—*i.e.*, the phase and magnitude of the effective E.M.F. through a resistance r, and producing the effective charging current, is represented by the line O F′. But, by what was proved in the last chapter, the phase of the charging current must differ by a quarter period from that of the difference of potential of the plates of the condenser.

Therefore O F′ must be at right angles to C E′, and the angle D E′ C is a right angle. Therefore E′ must lie in the circumference of the semi-circle described upon C D as diameter.

Further, since $\frac{OF'}{r}$ is the effective charging current, the maximum accumulation of electricity is $\frac{OF'}{r}\frac{T}{\pi}$, and therefore, if C is the capacity of the condenser, the difference of potential of the plates of the condenser will be $\frac{OF'}{r}\frac{T}{\pi}\frac{1}{C}$, which therefore should be equal to E′ C.

But O F′ : E′ D :: C O : C D by similar triangles.

$$:: \overline{R+r} : R$$

$$\therefore OF'=E'D\,\frac{\overline{R+r}}{R}$$

Hence $$E'D\,\frac{\overline{R+r}\,T}{rR\pi C}=E'C$$

Therefore $$\frac{E'D}{E'C}=\frac{C\pi Rr}{T.\overline{R+r}}$$

or tan D C E′ = tan D C E.

Therefore C E′ must coincide with C E in direction, and because E′ lies upon the semi-circle on D C, it can occupy no other position than E; or E C is the effective E.M.F. in R, and by consequence O E is the effective E.M.F. in r.

The only point remaining to be justified is the direction in which the angle O C E has been taken. Had it been taken on the other side of O C, it is clear that E C would be at a maximum a quarter period *before* $\frac{OF}{r}$, the effective charging,

Digitized by Google

which would be absurd. Hence the construction is completely justified.

Now, it is evident, from the mode of construction, that O E must always be greater than O D. But had there been no condenser in the system, it is clear that O D would have been the effective E.M.F. through the resistance r. The effect of the condenser, then, has been to increase the effective E.M.F. in this section, and of course also to increase the current resulting from it.

On the other hand, E C must necessarily be less than C D, which is the longest side of a right-angled triangle, of which E C is one of the other sides. But without the condenser C D would have been the effective E.M.F., through the section whose resistance is R. The effect of the condenser in the system upon this portion of it will be, therefore, to diminish the current.

Hence, if the whole circuit before the introduction of the condenser contains a number of incandescent lamps in series, the joining up with the plates of the condenser will have opposite effects upon the lamps in the two portions of the circuit. The light of those situated between the condenser and the generator will be augmented, and that of those in the remote section will grow less intense. This effect depends entirely upon the value of the tangent of the angle O C E, which is equal to $\frac{C\pi Rr}{T(R+r)}$, and therefore increases as the capacity of the condenser increases, and as the period diminishes.

A further question is that of the change of power employed. By what was demonstrated in the first article, the power of the source of any harmonic source of E.M.F. is equal to half the product of the E.M.F. and the current passing through it, multiplied by the cosine of their difference of phase.

In the case before us the E.M.F. of the generator is O C; the current through it is $\frac{OE}{r}$.

Therefore the power is $\frac{OC.OE}{2r}.\cos COE$.

If E H is drawn perpendicular to O C,

$$OH = OE\cos.COE.$$

Therefore the power employed is $\frac{OC.OH}{2r}$.

But had there been no condenser, or if the capacity of the condenser vanishes, O H would have been coincident with O D, and the power would have been $\frac{OC.OD}{2r}$.

Therefore the effect of the condenser has been to demand a change of power in the ratio of O D : O H.

Since O H must always be greater than O D, the change is always in the direction of augmentation, and we are therefore justified in thinking that such an arrangement might be beneficially employed in regulating the intensity of lamps; for though in the remote section the light suffers by the introduction of the condenser, there is upon the whole an augmentation of power at work.

The actual power in the two sections of the circuit will be $\frac{OE^2}{2r}$ in the generator's section, and $\frac{EC^2}{2R}$ in the remote section.

These, of course, when added together, are equal to the power of the source, *i.e.*, to $\frac{OC.OH}{2r}$, which any one can verify from the geometry of the figure.

It may be interesting to note, however, that we can exhibit the powers in the two circuits as the products of certain lines in the figure divided by the *same* denominator, so that they can be compared by the mere multiplication of measurements taken with a pair of dividers.

The power in the remote circuit is $\frac{EC^2}{2R}$; but E C : E F :: R : r, therefore $\frac{EC}{R}=\frac{EF}{r}$, and the power becomes $\frac{EC.EF}{2r}$ while that in the generator's circuit is $\frac{OE^2}{2r}$, and the total power is $\frac{OC.OH}{2r}$.

Therefore they can be compared with each other by measuring

$$EC.EF,\quad OE^2,\quad OC.OH.$$

Also, since C H : C E :: F E : D O. Therefore, C E . F E = C H . D O.

Therefore, the three powers are again as

$$CH.DO : OE^2 : OC.OH;$$

and we have only to divide by $2r$ to obtain the absolute powers.

(TO BE CONTINUED.)

THE MECHANICS OF ELECTROLYSIS.

BY A. BANDSEPT.

(CONCLUDED FROM PAGE 333.)

II.

In industrial electrolysis, the theoretical arrangement of the voltmeter has generally been abandoned. The arrival and departure of the current take place precisely at the places where the charges of the polarised elements accumulate. It is therefore not possible to obtain the complete exhaustion of the dissociated radicals; and a considerable portion of the gas escapes without producing any useful chemical effect. This difficulty is remedied by reversing the poles and by completely immersing the electrodes. The dissociated radicals are drawn along by convection to the top of the plates or wires and expand there. The grouping and accumulation at the polar surfaces are no longer interfered with by the vibration resulting from the passage of electricity. At the moment of their being set at liberty, the constituents of the liquid become subjected to two forces acting in opposite directions—one is the polar attraction, which projects the element towards the origin of the circuit; and the other, acting subsequently, is the convection, which directs the radical partially discharged towards the upper portion of the plate, where penetration is easier, and where the release takes place in consequence of a fresh condensation of the gas.

A few considerations as to the mechanism of electrolysis in these two cases will give an opportunity of estimating the importance of the results obtained by this modification in the working of the apparatus.

(A.) In the former system—ordinary arrangement with connections at the top of the electrodes—there are two cases to be considered, corresponding with the effects produced at different points of the acting surfaces and at the various stages of the work.

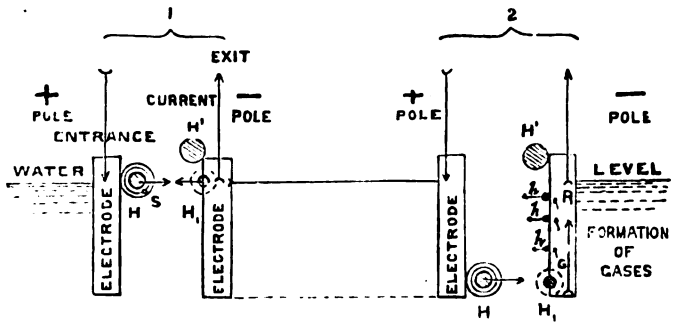
1. When decomposition takes place mainly at the surface of the liquid, the hydrogen, H, in arriving at the negative, is partially condensed at H_1, and gives up the energy which is absorbed by the polar substance. The elements which escape condensation are again transformed into gas, taking with them their own charges and the quantity of heat necessary for their formation into molecules H′. Sometimes, instead of the occlusion of hydrogen by the surface of the negative, combination takes place with one of the compounds of the latter; nevertheless, as there is always a question of condensation, the above explanation applies indifferently to the two kinds of action.

2. When, on the other hand, the reduction is specially active in the lower layers of the electrolyte, the phenomenon is complicated by a new effect, that of the absorption, in reduced proportion, of the charge itself given to the electrode by the work of polarisation. In fact, the elements $h\,h$ which escape condensation at H_1 encounter, in their upward move ment along the plates, a continually increasing resistance to penetration. This accession of reaction is due to increased potential of the plates and to the accumulation of the electric current at the point where it leaves the apparatus. The gases

Digitized by Google

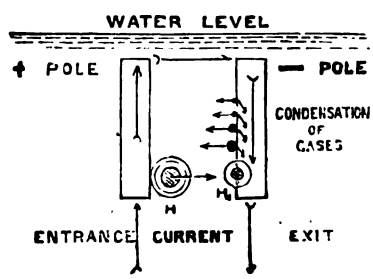
in rising, tend to put themselves in equilibrium with the differently charged zones which they traverse; they absorb energy for their progressive expansion and for their subsequent formation into molecules.

Diagram of the molecular actions of electrolysis according as the connections are made out of the water and at the upper part of the electrodes, or are arranged at the lower portion with complete immersion.



FIRST SYSTEM—ORDINARY CONNECTIONS AT THE TOP.

Maximum of re-action at R_1 by the accumulation of current and increase of potential of the plates. Formation of gases lost at G by absorption of energy.



SECOND SYSTEM—REVERSAL OF THE POLES OR CONNECTIONS. UNIQUE CASE.

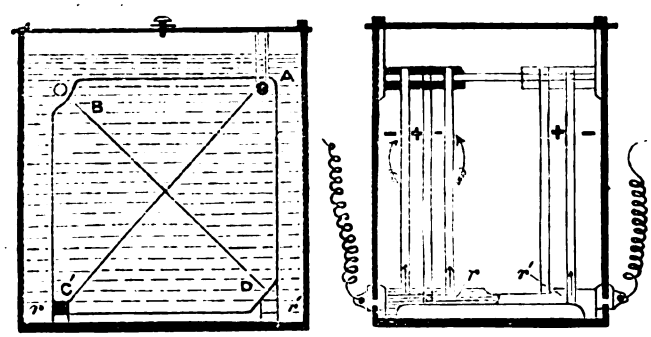
Minimum of resistance at r through the effect of aspiration due to the current and to the reduction of the reactive charges of the polarised plate. Condensation of the elements that have escaped at H_2, and recuperation of their energy.

(B). But when the poles or connections are reversed—that is to say, when the current is made to enter and pass out at the lower portion of the electrodes, the latter being entirely submerged, the loss of gas can no longer take place.

It will be remarked, in the first place, that during any given period of the charge, and at every degree thereof, the maximum of decomposition takes place in the lower layers of the system; the current arrives there with all its intensity, and yields to the dissociated radicals all the energy which they are capable of storing up. The effects of polarisation of the plates take place, therefore, at full pressure. A certain portion of the reducing element always escapes the condensation which takes place at H_1; but the gaseous bubbles *h h*, instead of expanding, as in the former system, become recondensed at the upper part of the electrodes; since the surfaces there are more permeable, on account of the reduction of the reacting polar charges and of the drawing-along action (*entraînement*) caused by the current. The gaseous elements are, therefore, completely exhausted by a mechanism analogous to that which occurs, during the expansion of steam, in compound engines. Just as, in these engines, the larger cylinder serves for the exhaust of the smaller, so here the upper portion of the plate serves to collect the motive power which the gaseous elements are still capable of exerting, no longer by their expansion, but by their condensation in a medium or chamber of lower pressure. By analogy, again, with what takes place in compound engines, in which the irregularity of the strains is much less than in a single-cylinder engine, a yield, or *régime* of discharge, more constant than that which is now supplied, is obtained from the new electrical arrangement. The influence due to the loss of gas is thus greatly diminished.

In electrical accumulators, the theoretical arrangement of the voltmeter has been abandoned, probably through want of combination which permits of putting in practice the method naturally indicated. It seems, in fact, more elementary to reunite the terminals of plates out of the water, as is generally done, and to place heavy masses of lead on the bracket at the bottom of the tanks. However, on examining matters more closely, it will readily be seen that the installation loses nothing of its simplicity when the problem of utilising the energies lost by the escape of the gases is approached. Not only is the solution practically possible, but it also leads to this immediate result, an effective reduction in the weight of the electrodes. It is not necessary, in fact, to provide the plates with two classes of terminals; the latter may, on the contrary, be entirely suppressed, and all the surface of the plates be made to participate in the electrolytic action.

Let A B C D, in the accompanying diagram of a battery, be a rectangular plate, suspended at A, the right hand upper corner, and resting at C, the opposite lower angle,



on a small rod of lead, *r*, which serves as connection. This rod is placed lengthways at the bottom of the bath, and sustains all the weight of the electrodes of the same name. By cutting off the angles B and D, it is possible, by turning the plates and arranging a system of suspension and support, symmetrical with the first, to arrange an electrolytic apparatus, presenting the maximum of useful surface for a given weight of electrodes of any given system. There is, in such a case, an increase of useful effect and also an increase of capacity for storage.

III.

An appreciable increase in the power of accumulators has lately been announced. It is evident that, at present, no limit can be assigned to the capacity for storage of a given weight of matter; it is not sufficient, in fact, to estimate the yield according to the fundamental law of equivalents, since no one knows exactly what the chemical reactions are which occur in the battery. Next, such a yield, however well it may be calculated, only answers to the special and relative conditions of the system under consideration, conditions which may be completely modified by physical influence. The nature of the electrodes exerts on electrolysis a chemical, a physical, and a mechanical influence. All three resolve themselves into penetration, the degree of which determines, in its turn, the power of absorption—that is to say, the power of utilising radical charges. They correspond with the effects due to the different orders of interstices of the electrodes—interstices atomic, molecular, and porous.

There is, therefore, ground for considering, in the first place, the kind of porosity which is most suitable for polarising surfaces; and, from this point of view, the natural or electrical formation is evidently the best, on account of the regularity and the fineness of the interstices, which permit of obtaining a more complete and more prolonged condensation than in the case of oxidised substances added to the plates. The work is coarser when the oxides of commerce are employed; and an electrode thus composed may be defined as constituting an increase, at every step, of the polar surface naturally formed, giving rise to another order of mechanical reactions.

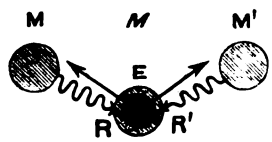
The electrode is a centre of action, the influence of which decreases with the distance. The groupings, determining the combination or occlusion, become so much less perfect as the new elements are less directly turned towards the "attracting" body. It may be said that, in general, the deposit loses in quality what it gains in thickness. A filiform electrode is, therefore, the most perfect in theory, because, the more

Digitized by Google

numerous the centres of action for a mass of matter which has a tendency to connect itself therewith, the better will the various groupings be established, and the better also will the *vis viva* of the dissociated elements be utilised. This consideration shows that the method of adding to the plates thick layers of matter is contrary to the principle which governs the polarisation of the *ions*.

As the reduction progresses partly in an inverse direction to the decomposing current, it follows that the combination of the radicals with the substance added does not take place at the origin of the motion—that is to say, at the centre of attraction, but simply in its neighbourhood, at a considerable distance, due regard being had to the minuteness of the molecular effects corresponding with the transformations. In a word, the charge of the radicals into each of the zones of the electrode is not completely utilised, since these radicals do not acquire all the speed of which they are capable.

To generalise. Under the supposition of an ideal electrolysis, it is a question of decomposing a molecule E into two others, M and M′, offering resistances $\pm R$ and $\pm R'$. It is evident that the energy stored up for this separation will include that which is necessary for the disorganisation of the grouping—affinity—of E in a medium *M*, in addition to that which must be expended for the penetration of the molecules M and M′. The energy set to work may therefore vary within very wide limits if the relative conditions of the system also vary. The more difficult the dissociation of the element



E in the medium M *M* M′, so much the more energy will it store up, which energy will be entirely restored under the conditions of the hypothesis. There will be no limit to this storing-up until the absolute capacity for motion of the substance be attained.

The reducing power of a radical of hydrogen in the nascent state, for instance, varies according to the reaction which has produced it. If the medium changes in which the combination is effected, it follows that, at the moment when the radical re-issues from the combination, it is accompanied by the whole quantity of heat generated during its release. Its formula, which was H *calories* (heat units) will become H + *n calories*; and the hydrogen will be so much more active as the value of *n* is greater.

There is, therefore, nothing impossible in the attempt to get a higher percentage of useful effect from an accumulator than that which has hitherto been accomplished.

ON THE SEAT OF THE ELECTROMOTIVE FORCES IN THE VOLTAIC CELL.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

(CONTINUED FROM PAGE 356.)

Compensation methods of a sort had been used before by Gerland and by Thomson. Gerland applied compensation to determine the E.M.F. of two metals dipped into a liquid, and Thomson applied it to the divided-ring experiment, thus making it very analogous to that of Pellat.†

Pellat also adopts Sir William Thomson's view that the Volta effect is due to a true contact-force between the metals, and that it represents a real difference of potential between them when in contact; at the same time he is careful to point out that no rigorous proof can be given of this, and that all that is really and certainly measured electrostatically is the difference of potential between what he calls the electric coats (*les couches électriques*), or what may be more simply called the air-films, on the two touching metals.

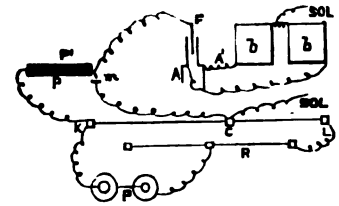


FIG. 6.—Diagram of Pellat's Method.

p′ p, plateaux du condensateur (*p* fixe, *p′* mobile).
m, interrupteur.
F, feuille d'or.
A et A′, plateaux attractifs de l'électroscope.
b b, batteries de 100 volts chacune pour charger les plateaux A A′.

The diagram, Fig. 6, pretty well explains itself. The contact at *m* is broken the instant before *p′* is raised.

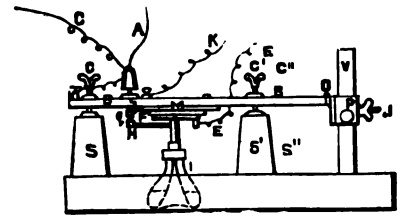

FIG. 7.—Pellat's Condenser.

Fig. 7 shows how this was done in practice. Pulling the string, A, raises a sliding-pin with a shoulder, *q*, fixed to it a millimetre below the bar, B. The pin thus first breaks contact near H, and then raises the hinged bar B B, to which the upper plate, M, is attached. The upper plate, being always in connection with a battery, requires no special insulation. The lower plate is carefully supported by a Thomson insulator, I. The lower plate was considerably smaller than the upper one, and it was further protected from stray inductions by a guard-screen. Screws, *c c*, served to regulate the distance between the plates.

The following is a summary of some of Pellat's measurements, gold being the metal with which all are compared, and the numbers being given in volts.

4. Meanwhile some experimenters, starting with a belief in the chemical origin of the Volta effect, had made experiments supposed to support this view. Mr. J. Brown, of Belfast, in 1878, repeated Thomson's divided-ring experiment,* as well as Kohlrausch's condenser experiment, in other gases than air; and found a very decided difference, and even a reversal of sign, when sulphuretted dydrogen was substituted for air. The metals Brown used were copper and iron, and he obtained a 1-centimetre deflec-

* Reprinted from the *Phil. Mag.* for March.

† I find, indeed, that Sir W. Thomson completely anticipated Pellat in the application of galvanic compensation to the measurement of Volta effects; for in *Nature*, April 14, 1881 (vol. xxiii., p. 567), is printed an account, given in brief at the Swansea meeting of the British Association (see Trans. of Sects., 1880, p. 494), which relates how the divided-ring experiment naturally developed into more complete compensation with slide resistances, and that an extensive series of measurements were made on this plan in the years 1859-61 with results quite in agreement with those published by Hankel in 1862. Other experiments were made since 1861 with results confirmatory of those of Pfaff, 1821, showing the Volta effect to be independent of the surrounding gas. The description of all these experiments was therefore withheld till something new should be obtained by the method, and was not published until Pellat's paper had appeared in the *Journal de Physique*, May 1880. Fig. 10 sufficiently exhibits Sir William's arrangement. In a postscript are described a few additional experiments of the same kind as those published in 1881 by Schulze-Berge, in which a platinum plate is soaked for a certain time in dry oxygen or oxygen, and then used in the Volta condenser. The observation is made that merely soaking a plate in gas is more effective than electroplating it with the same gas with an E.M.F. of a volt.

* J. Brown, Phil. Mag. August 1878, Feb. 1879, and March 1881; see also Brit. Assoc. Trans. of Sect. 1881, and 'Electrician,' vol. vii. p. 165.

tion in the direction indicating iron + in air; while in SH_2 he obtained a a 3-centimetre deflection, indicating that iron was —. On readmitting air the deflection again reversed, and so on until the copper coated itself with a blue film of sulphide, when the deflection became undecided, owing, as Brown supposes, to "the cessation of chemical action."

In 1881 he observed a time-change (decrease) of the Volta effect at a copper-zinc junction, and reckoned that at the first instant after cleaning the potential difference would he as high as ·9 Daniell, "which," he says, "agrees with J. Thomsen's determination of the difference of the heats of combustion of zinc and copper and oxygen." He here gives a hint of holding a heterodox notion which I do not find in any other of his writings, and which I believe he abandoned, even if he ever really held it.

In 1879 Brown tried a copper-nickel divided ring, substituting HCl for air, and here also succeeded in obtaining a reversal of sign. He also arranged a divided ring of wet blotting-paper, and showed that there was a difference of potential when the two halves were touched with a zinc-copper couple (which is not remarkable); but he then goes on to draw a moral, and to say that the slit of the divided ring corresponds to the air-film, and the wet paper to the moisture film in the ordinary Volta-condenser experiment. The film of moisture on the zinc plate is thus shown to have a + charge, and that on the copper a negative. If it be objected that the better the plates fit, the better the manifestation of contact E, it is to be replied that it is not to be supposed that there is no air between them anyhow (says Brown). Probably, he says, gas produces the difference of potential only so far as it forms a film on the surface. When a metal and a liquid are experimented on, it is probably really a two-fluid cell, the other fluid being that condensed on the surface of the metal.

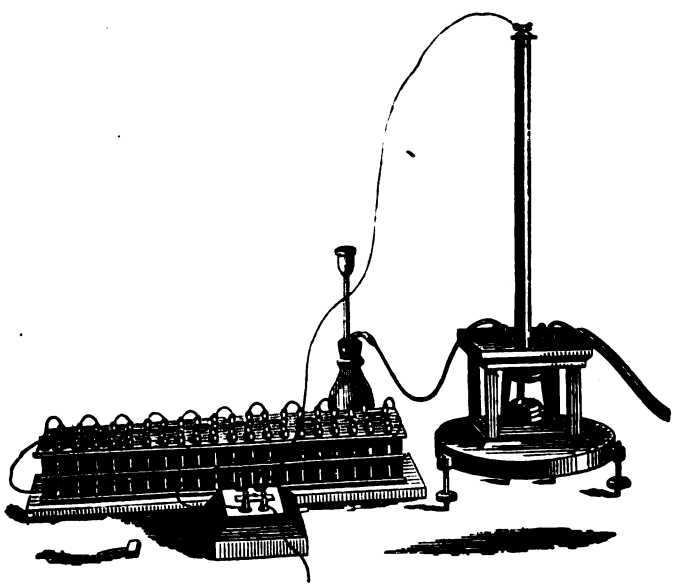

Fig. 8.—Mr. J. Brown's Arrangement for observing the Volta Effect in different Gases by Sir William Thomson's Method of a bimetallic ring with an electrified needle hanging over it.

Brown thus goes strongly for the activity of the films, or condensed air-sheets, which certainly exist on the surface of solids, and which may play an important part in the matter; but he supposes that these films act by corroding or attacking the plates, and that such a film is necessarily existent between surfaces nominally in contact if any Volta effect is to be produced; so that if the metal faces really and truly touched all over, they would show no charge when separated. Moreover, he lays it down that the potential difference is only observed while chemical action is going on; but that so soon as it ceases, from any cause, at once the Volta effect ceases too. In all this I entirely differ from him; but his experiments are very interesting and much to the point.

They cannot, however, be regarded as settling the question—the very important and fundamental question—as to whether the Volta effect depends on the atmosphere or medium surrounding the plates, or whether it is an absolute effect depending on contact alone. Experiments on this point are absolutely discordant; and it seems to be one of those points which it is very difficult to settle by direct experiment. For if by using a chemically active gas instead of air, you get a positive result or change in the Volta effect, the answer from the other side is "Yes, of course, because your plates are corroded and coated with sulphide or chloride, or something whose contact-forces come in and modify everything." If, on the other hand, you get a negative result when you substitute some inert gas like hydrogen for air, then it is objected that you have not removed the air-film which the plates had contracted from long standing in the air; and if you answer indignantly that you did, and that your hydrogen was perfectly pure, it is replied with a sneer, "Oh, yes, it is not so easy to get pure hydrogen as you seem to think."

Moreover, suppose a positive effect on changing the gas *was* established; what then? Nothing is settled except that the metal/air contact-force is proved to be somewhat different from the metal/gas contact-force. There seems to be really no way of knocking contact-force on the head experimentally, and this probably because it is a reality: *there really is* a contact-force at every junction of dissimilar substances; and the E.M.F. of a circuit, whether it be inductive or conductive, is always the sum of such contact-forces. I do not say that the contact-force at any given locality has the value ordinarily assigned to it as the result of experiment.

The earliest attempt made to examine the question as to whether the Volta effect depended on the atmosphere was made by Pfaff* in 1829, who used dry and damp air, oxygen, nitrogen, hydrogen, carburetted hydrogen, and carbonic acid, and he found that there was no difference so long as no visible chemical action occurred; but it must be noted that the opposing faces of his plates were varnished. De la Rive, on the other hand, asserted that there was no Volta effect in the slightly rarefied air then known as "vacuum."

In recent times Pellat has investigated the subject, and has come to a conclusion in agreement with Pfaff, viz., that the differences are very small. The metals used by Pellat were copper and zinc, and the gases were air dry and damp, dry oxygen, dry nitrogen, dry and pure hydrogen, dry and pure carbonic acid. He finds slight variations, but exceedingly slight, and such as Pfaff, Exner, and Brown could hardly have detected. He says:—"Au surplus il est fort probable que, si quelques-uns des auteurs précédents avaient tenté les expériences que j'ai faites au sujet des gaz, ils auraient trouvé des résultats négatifs; les faibles variations produites par le changement des propriétés du gaz que j'ai pu mettre nettement en évidence, grâce à la précision des mesures, sont au-dessous des erreurs expérimentales de leurs méthodes, ou à peine supérieures dans les cas les plus favorables."

In all the above gases he has also studied the effect of varying the pressure. Lowering the pressure slightly *increases* the observed difference of potential; but the change lags a little behind the pressure-variation. Damp and dry air behave in the same way. In oxygen the effects of pressure are rather better marked. Nitrogen gives nearly the same numbers as air; but after it has been in for some time, the numbers are slightly lower than at first. Hydrogen gives a little greater effect than even rarefied air; rarefying hydrogen does not alter it much. Carbonic acid gives the same numbers as rare air or dense hydrogen. As for liquids, plates wetted with alcohol give the same result as if immersed in plain air.

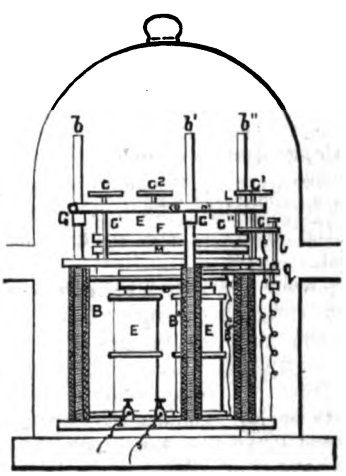

Fig. 9.—Pellat's Apparatus for experimenting in different Gases and a different Pressures.

The movable plate is now the lower one, and it is pulled down by an electro-magnet, E, a little way against the springs, B, which tend to drive it up against the screw tops, C. Contact is automatically broken at *q* the instant before separation. The bell-jar has 35 litres capacity, the diameter of each plate being 15 centimetres. It must be impossible to employ anything like pure gases in a bell-jar enclosing such a bulky mass of heterogeneous material; and the pressure was found not to go below 2 or 3 centimetres of mercury. However, he has since made a smaller arrangement of 1 litre capacity, with plates 9 centimetres diameter, and, what is more important, with the electro-magnet outside, and nothing inside but glass, mica, and metal. In this the pressure goes down to a millimetre. But even this is not all that could be wished. Moreover, the experiments described had been made with the larger apparatus.

Von Zahn† also tried a condenser in various gases, and found no difference; but when he tried a platinum-zinc condenser in the highly rarefied air now known as vacuum with some melted sodium in a branch tube to absorb all the oxygen, the Volta effect was diminished, and only represented a potential difference of half a Daniell. I am not clear whether sodium can be trusted to ultimately absorb every trace of oxygen; but I should judge it would take a very long time: and as to rarefaction, dividing the numbers of molecules in a vessel by a million or two leaves them quite numerous enough to accomplish anything they want.

Sir W. Thomson has also made experiments in different gases with negative results.‡ These experiments are not described in detail, but they were made with the apparatus shown in Fig. 10.

* Pfaff, *Ann. de Chim.* 2 ser. xli., p. 236. The metals he employed were copper, tin, and zinc.

The views of Ayrton and Perry on the subject of the effects of atmosphere underwent modification between their first paper and their third. In their first paper they say they have good reason to believe that there is no great difference of potential between a metallic or liquid surface and the air in contact with it.

Clerk Maxwell, in a letter to *The Electrician*,* pokes fun at them for this, saying:—"A statement like this, coming from men whose scientific energy is threatening to displace the centre of electrical development, and to carry it quite out of Europe and America to a point much nearer Japan, is worthy of all attention, even without an explicit statement of their 'good reason.' But Mr. J. Brown has shown (*Phil. Mag.*, August, 1878) by the divided ring-method of Sir W. Thomson, that whereas copper is negative with respect to iron in air, it is positive with respect to iron in H_2S. It would appear, therefore, that the reason why the results of metals by the ordinary 'contact-force' experiments harmonise so well with the comparison by dipping both metals in water or an oxidising electrolyte, is not because the E.M.F. between a metal and a gas or an electrolyte is small, but because the properties of air agree to a certain extent with those of ordinary electrolytes. For if the active component of the electrolyte is sulphur, the results are quite different; and the same kind of difference occurs when hydrogen sulphide is substituted for air."

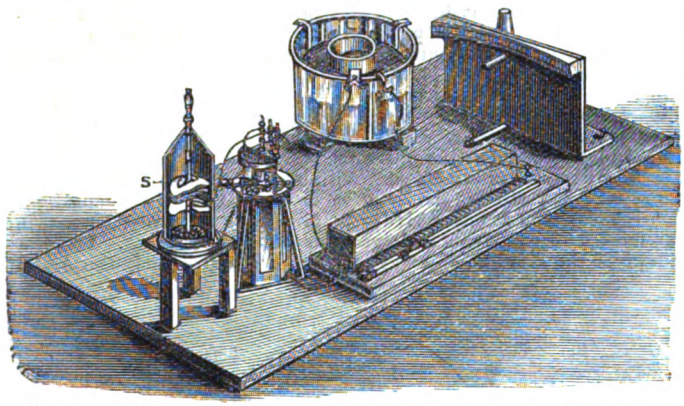

Fig. 10.—Sir William Thomson's Compensation arrangement for measuring Volta force in air and gases by a null method, devised and used in 1859, published in 1880.

The upper plate of the condenser is uninsulated, and slides up and down from one-fiftieth to a quarter or half an inch from the lower insulated plate, which is permanently joined to the electrometer. The upper plate is put in communication with the lower one momentarily through the slide resistance, and is then raised, the position of the slide being adjusted till no deflection ensues.

In their third paper,† therefore, we find Ayrton and Perry's views changed, and they clearly state that their experiments, like all those based on inductive methods, leave the question of air contacts quite undecided.

They then go on to say:—"One way of determining the E.M.F. of contact in volts between a substance and air, and a way we hope shortly to employ, is to repeat all these exact contact experiments in different gases [it is not quite true that this would give the results required, because it would only give differential effects; very important to observe, no doubt, but not the same as observing the actual contact force of air or of gas]. . . . . We shall thus ascertain whether the contact difference of potentials of a substance and a gas differs much for different gases. Qualitative experiments in this direction have already been made with very interesting results by Mr. Brown of Belfast, but his experiments differ from ours in not being quantitative." [Only, as their experiments do not yet exist, Mr. Brown's have still some value.]

In vol. xii. of Wiedemann's *Annalen*‡ I find some interesting experiments by Schulze-Berge on contact-force between metals and gases. He uses a condenser and different gases, but the plates of his condenser are both of the same metal, and he coats one of the plates with a film of the gas, say chlorine, or hydrogen, or ozone, and leaves the other covered with air. To measure the potential difference he employs the compensation method of Pellat, and his arrangement seems fairly satisfactory. But he does not explicitly enter on the question as to the seat of E.M.F. in the Volta experiment (except in a controversy with Professer Exner). He assumes that a contract force between metals and metals and between metals and liquids has been established, and he wishes to extend it to the contact of a metal and a gas. Believing firmly in the existence of films of condensed gas at the surface of a solid, which films require time for their formation or removal, he deems it sufficient to soak one of the plates of his condenser in the gas to be examined, and then to take it out and measure the difference of potential between it and the other plate coated only with a film of air. Tried thus, ozone rendered gold, platinum, and brass negative as against the corresponding air-covered plate. Hydrogen rendered its platinum strongly positive; but its influence on gold was slight, and on brass uncertain. Chlorine and bromine made platinum negative, and ammonia made brass positive.

(TO BE CONTINUED.)

PHILADELPHIA EXHIBITION.

(CONTINUED FROM PAGE 337.)

THE ELECTRIC TUBE COMPANY.—UNDERGROUND CONDUCTORS.

The essential form of the conductors exhibited by this company is that of an iron tube containing one or more copper conductors insulated from each other and the enclosing iron tube, and having all remaining spaces in the latter filled with an extremely viscous, almost solid, insulating compound, which becomes fluid at a high temperature. This manufactured product is termed an "electric tube." These tubes are manufactured in fixed lengths, generally 20ft. The conductors project from 2in. to 3in. beyond the end of the enclosing iron tube, and two lengths of electric tube are joined together by means of copper joints soldered to the projecting conductors and so formed as to allow the expansion of the conductors to take place without injury or danger. Such joints are protected by a cast-iron box completely enclosing them and securely fastened to the ends of the tubes enclosing the conductors. This box is then filled with the same compound as the tube and hermetically sealed.

The exhibit of this company showed the great range in the size and number of conductors which the fundamental form of cased conductor permits, and the great flexibility in making circuits of complicated ramifications, which is given by the plan of having joints at frequent intervals, and the methods of making these joints.

To illustrate the range in size, &c., samples of electric tubes were shown containing conductors varying in number and size, from a single round conductor 1·61in. diameter, of 2,592,100 circular mils. or 2·036 square inches sectional area, in an iron tube 2⅞in. outside diameter, to 271 wires No. 14 Brown and Sharpe gauge, of 4,100 circular mils. or ·00322 square inch sectional area, in an iron pipe 3¼in. outside diameter.

To show the manner in which circuits of a complicated character may be made with this form of conductor, circuits such as those used for incandescent lighting on a large scale, having a large number of derived circuits with conductors of widely differing sizes, there was exhibited a portion of an underground circuit such as is used in T. A. Edison's 3-conductor system of incandescent lighting—a system using tubes of which the cross section is shown by Fig. 1.

This exhibit consisted of—first, a "junction safety catch box." This is a large round box, the top of which is flush with the surface of the street. It is provided with a loose outside cover, and a lighter inside cover bolted down to make a water-tight joint with the box; these being removed, disclose the internal electrical connections in a readily accessible position, six inches below the surface of the street. The central portion of the box is occupied by the "pole pieces," consisting of as many rings as there are conductors in the system (in this instance three), each ring having as many radial projections as there are tubes entering the box (in this instance six). These projections, which are symmetrically arranged as regards polarity, are all brought to the same level at their extremities, and terminate in plane, polished, gold-plated surfaces one inch square, which are arranged equidistant from each other in a circle around the centre of the box. Each of these surfaces has a tapped hole in the centre.

FIG. 1.

In a circle outside the pole pieces are as many "safety catch joints" as there are conductors entering the box (in this instance 18). These safety catch joints are arranged radially opposite the extremities of the projection of the pole pieces; each consists of a copper or composition piece which has a copper rod soldered into it projecting about eight inches downwards into the body of the box, the upper end of the composition or copper piece terminating in a plane, inch-square, gold-plated surface, the same as those on the pole pieces. These surfaces of the safety catch joints are on the same level as the similar surfaces on the pole pieces, and radially opposite and equidistant from them.

Two feet below the top of the box (that is the surface of the ground) the electric tubes (in this instance 7) enter the box and are rigidly attached to it, the joint being made water-tight. The pole pieces and the safety catch joints are all insulated from each other, but rigidly attached to a support rising in the centre from the bottom of the box.

Flexible copper cables join each conductor of each tube with one of the copper rods, which project downwards from the safety catch joints, so that by means of flat safety catches placed across from the safety catch joints to the corresponding projections of the pole pieces, all conductors of like polarity are joined together at this point with a safety catch in each circuit in a readily accessible position, where it can easily be removed or replaced. Such a box equalises the electromotive force at that point of all lines entering it, or if one of the tubes is a feeder—that is, runs back to the dynamos—the box is a distributing point for several circuits, which may or may not be brought together again at some other place.

The conductors in the tubes entering this box may be of any size to suit the requirements of the different circuits. The circuits shown entering this box vary from 350,000 circular mils. to 133,000 circular mils. area of conductor, and are arranged to show how they may be laid, bent in different degrees to right or left, joining each other at their extremities, crossing each other and joined together at the crossing, joining other circuits at any point in the length of the latter, reduced in size at any point of their own lengths, and having derived circuits of any size taken from them at any point of their own lengths, and having all these varied connections of different sized conductors

Digitized by Google

made by means of a comparatively small number of standard patterns of connecting joints, boxes covering the joints, and ball clamps attaching the boxes to the iron tube enclosing the conductors.

The ball clamps, in connection with the boxes, are essential features of all underground conductors of this company's exhibit.

Figs. 2, 3, and 4* illustrate the forms of these parts and the manner in which they are used.

Fig. 2 shows the top and bottom halves of a "coupling box," a 3-conductor system, and Fig. 3 a "ball lamp," whilst Fig. 4 shows the bottom half of the same coupling box with tubes and ball clamps in place and joints connected. The two parts of the ball clamp being bolted together on the tube are thus securely clamped to it, the hemispherical parts come together to make a sphere which fits the spherical socket in the nozzle of the box; the two together thus form a ball and socket joint, allowing free angular movement of the tube in any direction, but preventing longitudinal movement of the box on the tube. The angular movement allowed by the ball and socket is limited to any amount in any direction by providing a rib inside the box (either separate as in Fig. 11, or forming the inside opening of the ball-socket of the box, as in Fig. 2) of such a form, that when the extreme amount of angular movement to be allowed in any one direction is obtained, the tube projecting into the box through the ball clamp comes in contact with this rib, thus stopping any further movement in this direction.

The box is made of such size and form, that when the tubes have the extreme angular movement allowed there is still ample space between the joint and the box to prevent the two coming in contact. Rotary movement of the box on the tube is prevented by means of the small lug on the ball of the clamp, which loosely fits sidewise, the slot shown in the socket of the box, the slot being sufficiently elongated lengthwise that the lug may have free play in that direction within the limit of angular deviation allowed.

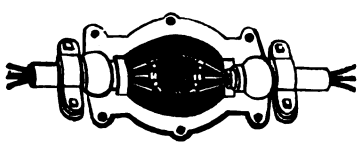

Fig. 4.

The limiting rib inside the box is made to give the angular movement allowed when the largest size of iron tube that will go into the box is used, but any smaller iron tube may be used in this box (as, for example, in reducing the size of the conductor at this point) by means of a ball clamp, of the form shown in Fig. 5, with a ball to fit the box, but with a smaller semi-cylindrical groove in each half to fit the smaller iron tube. This clamp has in addition, as shown, a semi-cylindrical ring concentric with the groove cast on the ball of each half, the two, when the two halves are clamped together on the iron pipe, forming a cylinder projecting into the box, of the same outside diameter as the largest iron tube that will go into the box. This projection on the clamp striking against the limiting rib inside the box limits the angular movement of the smaller iron tube to the same amount as when the largest size of iron tube that will go in the box is used. Therefore the ball clamp and box, as described, whilst making the iron envelope of the conductors mechanically continuous, and preventing rotary movement of the boxes on the tube, allow an angular deviation (in this case 1 in 10) in every direction, at each end of every box, which gives a degree of flexibility to the whole line (in this instance 11½ degrees at each joint), and at the same time renders it impossible that the joint should touch the box, with the extreme amount of angular deviation allowed. The ball clamp, modified as shown in Fig. 5, also permits the use in any box of any tube smaller than the largest that will go in the box, whilst preserving the same limit of angular movement.

Fig. 6.

The flexibility of the whole line thus obtained is necessary for rapid and cheap laying in streets, where, from the number of gas, water, and other pipes, sewer manholes, &c., it is impossible to run tubes in a straight line for any distance.

The joints for 3-conductor tubes consist of pieces of copper wire rope, having cast or brazed on their ends suitably shaped composition sockets, in which are drilled holes to fit the size of copper conductor for which they are intended, and to which they are soldered in laying the line. The joints necessary to obtain the results illustrated by the exhibit are: "coupling joints," for connecting two tubes in a straight line (Fig. 6 shows the form of one piece, three such pieces being used for a complete joint), "90° elbow joints," for bending 90° to right or left, and "45° elbow joints," for bending 45° to right or left. Fig. 7 shows three forms of pieces, different combinations of which will make all kinds of elbow joints—"branch joints," by which to any coupling joint in a line of any sized electric tube may be attached a branch to one side, or one to each side, of any sizes not larger than the main line. Branches of sizes larger than the main line, being of rare occurrence, are not allowed for in the standard patterns for branches enumerated below, but, when required, may be made by a slight modification of the latter. Fig. 8 shows three forms of pieces, different combinations of which will make, to either or both sides of any coupling joint, branches of all sizes ordinarily required; a few of the largest sized branches require special patterns of modified forms, which are enumerated below. The form of socket of the coupling joint shown in Fig. 6 gives the copper wire rope of the joint a bowed form when the joint is in place, to allow for the expansion of the conductors in each electric tube. The form of the joint when in place is seen in Fig. 2. Fig. 6 shows that, in addition to the hole which fits the conductor, each coupling joint socket has another hole drilled in it; the male sockets on the ends of the branch joint pieces (see Fig. 8) fit these holes and are soldered in them in attaching a branch joint; the female sockets on the other ends of the branch joint pieces are drilled to fit the conductors of the electric tube used for the branch lines. Fig. 9 shows a coupling joint with a branch joint attached, in the bottom half of the box used for covering this kind of joint.

The 3-conductor system, so far as it is exhibited, has 21 different sizes of electric tubes, having conductors varying from 500,000 to 27,000 circular miles sectional area. The enclosing iron tubes are of 5 different sizes, varying from 2⅜in. to 1 1-16in. outside diamater. All connections are made with 10 patterns of boxes, 8 patterns of ball clamps, and patterns of 43 pieces for all joints. Of the latter, 6 patterns are required for coupling joints for all sizes, 3 of these patterns are also used for elbow joints, which require 15 patterns in addition, making 21 patterns for all varieties of all sizes of coupling and elbow joints. The remaining 22 patterns are for branch joints, and 12 of these will make any combination ordinarily required, the other 10 being for use in cases which rarely occur.

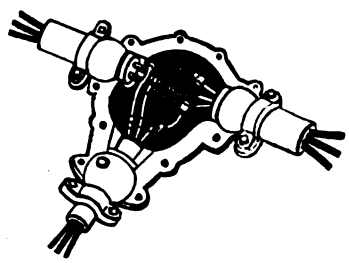

Fig. 9.

Electric tubes are exhibited cut away to show the internal construction, which consists in wrapping each copper conductor with a layer of insulating tape, and winding each taped conductor spirally with rope impregnated with insulation. The pitch of this winding is large compared with the diameters of the rope used, so that the windings of the several conductors fit between each other when the conductors are placed together. As many conductors as are to go in one tube, being so placed together, they are bound together by a final spiral winding of rope around them all, and the bundle of conductors thus formed being introduced into an iron tube, the process of manufacture is completed by filling the tube with insulating compound liquid, at high temperature, ready access being afforded the latter throughout the length of the tube along the spiral paths formed by the rope-winding of the conductors.

Another variety of electric tube is illustrated by an exhibit of a complete set of sample tubes for the 2-conductor system of incandescent lighting, and typical examples of the boxes, ball clamps, and joints used with them. The conductors in this system vary from 1,639,890 circular mills., or 1·2879 square inches, sectional area in a tube 3½in. outside diameter, to 33,015 circular mills., or 0·02593 square inches sectional area in a tube 1 1-16in. outside diameter, and, there being only two in a

Fig. 10.

tube, economy of space in the latter is secured by making the conductors in the form of segments of circles, as seen in Fig. 10, which shows a cross section of one of these tubes. The joints for these tubes are of cast copper, the allowance at coupling joints for expansion of the conductors being given by making the joints with a U-shaped bend, projecting at right angles to the line of the tube, the section of the joint in the U being flattened to a parallelogram, long in comparison with its width, as is seen in Fig. 11, which shows a coupling joint for this system of tubes, with bottom half of coupling box. Holes are bored in all joints of the same form as the conductors for which they are intended, and to which they are soldered in laying. Boxes are exhibited with short tubes entering them, and joints connecting the latter, showing the forms assumed by different sizes and varieties of coupling elbow and branch, joints and boxes. Fig. 12 shows one variety of one size of 90° elbow joint, with bottom half of elbow box.

In both the 3 and 2 conductor systems, boxes and joints are shown for use in in-door lines of these tubes. The flexibility of the line which is required for underground work, and which is given by the ball and socket connection of clamps and boxes, is not necessary in in-door lines; the boxes may therefore be smaller on this account, and also on account of the absence of the ball clamps, the mechanical continuity of the iron envelope of the conductors being secured in small space

* We have not thought it necessary to show all the figures. Those shown give all requisite details.

Digitized by Google

by means of a ring which is screwed on the threaded end of the iron pipe and fits in a groove cast in the neck of the box (which neck fits the iron tube). This box is made in halves, which are bolted together over the joint, the end of the tube, and the ring screwed on the latter.

Underground arc light circuits were illustrated by two exhibits showing the character of the tubes and joints and the method of taking loops to lamps. One showed tubes with two round conductors for a complete circuit in one tube.

Fig. 13 shows this exhibit, and the method of making the joint so that, the branch tube being led off to a lamp or lamps, the two conductors of the branch form a loop of the main line. The second exhibit shows the case of a circuit completed by a line on another street. In this exhibit the main line tubes entering the box have only one conductor each, the conductor of each tube being joined to one of two conductors of the third tube, forming a loop from the main line of a single conductor. The joints are of wire rope of the same character as the joints for the 3-conductor system. Ball clamps are used to connect tubes with boxes.

A distinct variety of electric tube is that designed for telegraphic and telephonic use. In this case, the conductors being large in number and small in size, instead of the spiral rope winding round each conductor, the insulating covering is continuous, and a rope winding is only used round the outside of a bundle of such wires. The wires are laid together regularly, on the basis of a hexagonal cross section for the bundle, and at each end are threaded through wooden screens which have holes drilled in them, in the same relative positions as the wires occupy in the tube. At one end of each tube, before being threaded through the screens, the wires are woven together so as to change the relative positions of the wires. This operation of weaving is simple and systematic, and the same for all tubes with the same number of wires, and is arranged on such a basis that, in conjunction with a systematic rotation of consecutive tubes, alternately to right and left, in the process of laying, it produces, in a series of long period, methodical changes in the relative positions of the wires in consecutive tubes, for the purpose of neutralising the effects of induction. In making the joints of these tubes, wires threaded through corresponding holes in the screens are bent outwards and placed together in the same notch of a series of notched wooden slats, one for each layer of wires in the joint, which are built up one above the other, as the process of making the joint proceeds. When all the wires are so bent out, the ends are clipped off, leaving about one inch projecting through the wall of notched slats; the insulation is then slipped off the ends, and each pair joined by a small sleeve, which is soldered to them to make the joint. In general, the joints of half the

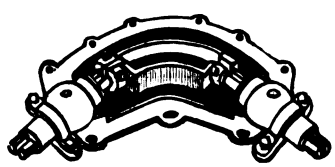

FIG. 12.

wires are made on one side and half on the other side of the box. Grooves are provided in the boxes, into which they fit the wooden screens through which the wires are threaded, and the series of wooden slats built up in making the joint, holding these securely in place. By this method of making the joints, every joint of every wire, at intervals of 20 feet, is brought into a position in which it is readily accessible for purposes of testing, making connections, &c., without interfering with any other wire, so that at any such joint, loops, or single service wires may be attached to any or all of the wires in the line. A line of this character, containing thirty-seven wires, was exhibited, with several consecutive boxes and joints to show the system of weaving wires in conjunction with alternate rotation of tubes. Such a line is adapted more particularly to telegraphic uses. Another box was exhibited, constructed with especial reference to the needs of telephone service, for which, in addition to trunk lines between stations, a number of wires are required for services in each block, and only run from the station to that block, thus giving a line between two stations a size decreasing gradually from each station to some point between them. The box exhibited, which showed a joint in a line of 217 wires, had a low turret rising from its upper half; the top of this turret was closed by a loose outside cover and an inside cover bolted down, and making a tight joint with the box by means of a rubber gasket, the whole being made water tight by filling the space between the two covers with the insulating compound. In every such box, along the face of a block, all those wires which are intended for use as services in that block are bent upwards instead of outwards in making the joint, so that the joints of all such wires project upwards into the turret and are held in position by a wooden frame shown, whilst the joints of all other wires are made out to the sides at a lower level. This arrangement allows the box to be filled with insulating compound, covering all the wires and all joints, except the joints of those wires intended for use in that block, which latter joints project up above the surface of the compound, and on removing the cover of the turret are all immediately accessible at every box along the block, for attachment of services, to any or all of them. Tapped holes are provided around the turret on the level of the joints of service wires, into which service tubes may be screwed, if electric tubes are used, or brass nipples to which are soldered the lead covering, if lead-covered wires are used for service connections.

This company also exhibits specimens of lead-covered wires of small sizes, and a specimen of flexible heavy conductor for indoor use, with large currents consisting of copper wire rope, taped, wound and lead covered. They also exhibit specimens of insulating tape, in rolls of 125 feet, continuous length, varying in width from 6 inches to ¼ inch, and jars of the insulating compound used in the tubes and boxes.

Comments by the Examiners.

This system may be summed up as belonging to division "A a" of the section's arrangement, or that in which the electrodes are permanently sealed. When any portion of an electrode is destroyed a new one is not introduced, but a new length of pipe is substituted, containing the necessary number of wires and attached at its extremities. The details are very fully given, and with the cuts render it unnecessary to repeat them. With a large stock of lengths and boxes and with trained workmen, the work of laying the conductors only a few inches below the surface of the streets would be comparatively rapid. While in the tentative stage of underground service this does not present the same amount of convenience as a system where wires may be introduced and removed at will; and presents the objection common to all "section" systems that the conducting capacity of the whole line is that of the most imperfect of splices made every 20ft., yet it answers the demands upon it much better than those systems which require expensive and tedious derangements of the street in order to accomplish repairs. The seat of an accident to one of the wires of this system is located from the central office, on and between known streets. The manhole is opened and the safety catches first of all examined. Managers assert that the place of the break can then be so accurately located that the length containing it (usually about 20ft.) may be at once removed and replaced by another.

The telephone and telegraph, and the light and power wires are not enclosed in the same tube. The insulating material with which the boxes are filled is still flexible at 32° F., but brittle at 0° F.

The method of laying and tapping for private dwellings would seem to afford complete protection against lightning. The three-wire system which has been grafted upon the Edison conduit system effects a saving of 62 per cent. on that required for the two-conductor system in the copper necessary for conductors.

The light and power system are not adapted for use by various companies, independently, though the telephone and telegraph conduits might be so applied.

The details of this system have been so perfectly elaborated, that in view of the fact that no complete description of it has been heretofore made public, the examiners deemed the above full report desirable.

(TO BE CONTINUED.)

ON CONSTANT ELECTROMOTIVE FORCE IN AN ELECTRIC LIGHT CIRCUIT.*

BY SIR DAVID SALOMONS, BART., MEMBER.

Although a considerable proportion of this paper is theoretical, yet abundant experiments were made before coming to any conclusions, and it is hoped that the result is not entirely without a successful issue.

Let the following points be assumed:—

(*a*) That the resistance of the leads be considered as *nil*, unless mentioned otherwise.

(*b*) That in all cases we are dealing with an incandescent light installation.

(*c*) That in all cases simple shunt dynamos are used.

(*d*) That the engines and dynamos employed are of ample size.

(*e*) That the accumulator is connected up in "parallel."

Now, for an increased resistance r in any circuit, that the current ($= C$) shall remain unchanged, and increased E.M.F. ($= e$) must be added, and if the original E.M.F. $= E$, and the original resistance $= R$, then

$$\frac{e}{r} = \frac{E}{R} \text{ and } \frac{E}{R} = C \therefore e = C r.$$

Hence, the E.M.F. must always increase by a numerical value which equals the added resistance in ohms multiplied by the original current in amperes. Further,

$$r = \frac{e}{C} = C^{-1} e,$$

that is, if the E.M.F. vary, then to keep C constant, the added resistance must equal $C^{-1} e$ (numerical value) ohms.

The reasons why the lamps in any installation are not usually steady are—firstly, that the motive power is irregular, or, in other words, the E.M.F. varies; secondly, the resistance of the circuit may vary and the dynamo not be capable of giving the required E.M.F. for all values of the current taken off; thirdly, a combination of both may exist.

It is seen that if the relations $e = C r$ and $r = C^{-1} e$ can be made to exist, the light will be perfectly steady.

In practice there is no convenient way of carrying out directly these relations, but the following are five methods of keeping the E.M.F. at the

* Paper read before the Society of Telegraph Engineers and Electricians, March 12, 1885.

Digitized by Google

lamps constant, or nearly so :—(1) By a regular motor ; (2) by the use of accumulators working alone ; (3) by the use of accumulators placed parallel in the circuit whilst the dynamo is running ; (4) by placing in parallel any counter E.M.F. ; (5) by various automatic means, magnetic and otherwise.

Method (1) can only be obtained under certain conditions which will not here be dealt with ; method (2) is practically perfect ; (3) is approximate, and will be the one now to be investigated ; (4) is a new method, to be described ; (5) will not be considered in this paper. Installations at 100 volts are in very general use, in which cases 50 cells of an accumulator are required at a time (if E.P.S. cells are used), each cell giving about two volts, and the resistance of all the cells equal approximately one-tenth of an ohm. In general it is found that the best charging current, not to injure the cells, is that which has an E.M.F. 10 per cent. higher than that of cells to be charged.* Hence, with an installation as above mentioned, 10 volts will be the margin, and we get $C = \frac{10}{0{\cdot}1} = 100$ amperes. Now, in point of fact, with most known cells under such conditions about 30 amperes pass. Hence, taking the resistance of the leads,† connections, &c., altogether, and probably some internal chemical actions besides, the resistance works out about 0·3 of an ohm. Let this be so. Let the adjustments of the installation be so made that the mean E.M.F. equal the correct working E.M.F. required for the lamps.

Then any rise or fall of E.M.F. due to the want of regularity in the motor must be neutralised, or nearly so, in order to make no perceptible difference in the light given by the lamps. One point is certain—that if, under the conditions mentioned, the E.M.F. should rise 1 per cent., the increased current sent through the cells will be three amperes, and so on in proportion for any other rise.

Now, in simple shunt machines whose brushes require much lead, the E.M.F. rises with a decreased flow of current in the outer circuit. Therefore a fall in the speed of the dynamo may be made to raise the E.M.F., and, on the other hand, the E.M.F. may be lowered in the case of a rise in the speed.

The important part played by the accumulator is due to the fact that its resistance is small as compared with that of the lamp circuit, and this is essential, for at those *moments* when the speed rises, and the E.M.F. rises with it, and the flow of current in consequence increases, all, or almost the whole, of this increase passes through the cells, so that no alteration takes place in the current flowing through the lamp circuit ; hence the E.M.F. remains practically unaltered at the lamps for any rise of E.M.F. at the terminals of the dynamo. Therefore, if a dynamo, as described and suitably constructed, is employed, very perfect regulation is obtained by the use of cells, whether the E.M.F. rises above or falls below the normal ; the cells and dynamo combined neutralising the rise of, and the dynamo making good the fall of E.M.F., since the variations in the speed are momentary.

If the increase of speed were to continue, there would be a general rise of E.M.F. throughout the circuit, that is, rapid variations would be counterbalanced, but a permanent and considerable rise in the speed would cause a slight and permanent rise of E.M.F. throughout the circuit.

From the foregoing we may conclude the following facts :—

(1) That it is necessary to use dynamos requiring a considerable lead for the brushes, so that the E.M.F. shall rise as the current flowing in the outside circuit decreases, and *vice versâ*, if it is required to steady the light given by the lamps by means of accumulators.

(2) That simple shunt machines, requiring practically no lead for the brushes, and consequently an E.M.F. almost constant for all values of the current flowing in the outer circuit (especially if the magnets are nearly saturated), are not so suitable for use with accumulators for the purpose of steadying the light, although they can be used with good results for charging the cells. For example : a Siemens' SSD_{10} machine (for 300 lamps of 20 candle-power), whose brushes require a considerable lead ; the variable current to the cells due to variations in the speed of the engine was 2 amperes (25 to 27 amperes to the cells). At the same time the variation in the lamp circuit due to any rise or fall of E.M.F. was absolutely *nil*, being steady at 24 amperes. The experiment was then repeated under the same conditions with a Crompton 14-unit dynamo (for 250 lamps of 20 candle-power), requiring a small lead for the brushes. Result : variable current to cells 2 to 3 amperes (25 to 28 amperes) ; variable current in lamp circuit 1 ampere (24 to 25 amperes). Consequently this dynamo did not regulate quite so well.‡

(3) That, in any particular installation, any apparatus or machine giving a counter E.M.F. equal to that of the accumulator in use, and having a like resistance, will steady the light just as well as the cells. This method the author believes to be quite new, and one capable of considerable development. For instance, a motor working parallel in the circuit, giving a constant counter E.M.F. (a motor not difficult to arrange), and having an armature of very low resistance, will effectually steady the lights with a very small expenditure of power. The chief advantage of cells is that most of the power is stored chemically, whereas in the motor-regulator it is lost—yet for many purposes the end gained is worth this loss many times over. It must also be observed that any motor, in a factory or elsewhere, with an unvarying load, and using a large current as compared with the "variable regulating current," will become a good motor regulator, with practically no loss of power. In most cases where motors are in use in parallel with lamps, some method can always be devised for making the motor regulate at the same time.

For another method, suppose the counter E.M.F. of the motor-regulator to vary, it will evidently do so in proportion to the variations of the E.M.F. in the lamp circuit. Hence the motor might regulate the steam flowing to the steam engine, or gas going to a gas engine, in such a way as to regulate the speed of the engine ; hence the E.M.F., very like an electrical governor in its action ; or the variations in the motor may vary the speed of the dynamo, leaving the speed of the engine unaltered. Or variable resistances might be inserted in the main leads, or in the F.M. shunt coils, &c.

The following is a very good way of inserting a counter E.M.F. in any installation :—Let the engine drive a dynamo (let it be called dynamo-regulator) in addition to the generator. If the speed of this dynamo-regulator is very high, and the belt driving it light, long, and slack, and its pulley made heavy to act as a fly-wheel, then this dynamo will have practically a constant speed, even when the engine is not running evenly, *i.e.*, the belt will slip over the pulley sooner than vary its speed, and the power required to drive it will be very small. To run the generator at a constant speed by this method would be too wasteful. Suppose this dynamo-regulator to be placed in "parallel," then it will give a nearly constant counter E.M.F., and this should be arranged to be nearly equal to the normal E.M.F. of the installation. It is evident that any variation in the E.M.F. above the normal, in the main circuit, will be neutralised in the same way as described in the case of the motor-regulator. Such a dynamo-regulator, employed in an installation where a gas-engine is in use for the motive power, and no accumulator, would be found invaluable, rendering the light quite steady, a result almost impossible at present, when only a few lamps are on, and at best there is a slight pulsation in the light. The power absorbed by the dynamo-regulator may approximately be estimated as follows :—Suppose the machine to be a "simple shunt," then the whole power required to drive it, so long as the gas-engine runs evenly, is equal to the power absorbed in revolving the armature when producing the F.M. shunt current. To produce a counter E.M.F., say, of 100 volts in a 100-lamp (20 candle-power) installation would require about 0·5 I.H.P. in a suitably-constructed machine. Hence this is a constant loss all the while the engine is running. Probably this loss of power is set at too high a figure. Now, when a gas engine is working near full power it runs fairly steady, and there will be but a trival variable regulating current passing through the dynamo armature ; hence, the loss of power under this condition will not be increased to any practical extent. But when the engine has only a light load on it, and its speed irregular, then the loss of power in consequence of the variable regulating current being larger will be greater, as much possibly as 0·5 I.H.P., so that, when few lamps are in use, the extra power required to steady the light will be about 1 I.H.P. This seems very wasteful, but a great difficulty is overcome : that of getting a perfectly steady light from a gas engine when only a very few lamps are in use, and the more that are in use at a time the less the loss, till finally the loss becomes very small as compared to the total power required ; yet all through the process the benefits of perfect regulation exist.

It will be observed that by all these methods both rise and fall of E.M.F. above or below the normal will be neutralised.

(4) That, if a variable resistance is employed in the shunt circuit of the dynamo, it is possible to charge the cells at any desired rate from the current given at the maximum E.M.F. the dynamo is arranged to give, down to *nil* ; and this plan avoids all necessity for altering the speed, and the loss of power is very small. This method has always been employed by the writer, and has many advantages in practice. It is thus possible to work on the lamp circuit and charge at any desired rate at the same time, and in addition any desired E.M.F. may be obtained in the lamp circuit.

But the condition exists that so long as any current is entering the cells, all the current to the outer circuit is supplied by the dynamo ; and this continues until the current to the cells, by means of gradually increasing the shunt resistance, is regulated down to *nil*, when unstable equilibrium ensues, and the current to the lamp circuit is at a given moment taken half from the dynamo and half from the cells, and this relation will continue for all values of the current within the limits of the installation.* These last remarks require a slight modification in practice, for they neglect the resistance of the leads between the dynamo and the accumulator, any variation of the resistance of the cells, and any difference in the relations between the resistance of the cells and that of the armature. If all these points are taken into consideration it will be found that the exact proportion of discharge from the dynamo and the cells, instead of being equal, will be somewhat different, but not very much so ; and in the writer's installation, after experimenting with many dynamos and two sets of cells, he finds the theoretical division to be very close in practice, the leads having a very small resistance, and the dynamos being fairly suited to the accumulators. Besides other advantages gained by this method, the cells cannot be injured by overcharging or be charged too rapidly.

In short, after the point of unstable equilibrium has been reached, a dynamo and accumulator work to the line very much in the same way as two batteries, giving the same E.M.F., placed parallel, would act under similar conditions. It is also seen that, in cases where dynamos requiring much lead for the brushes are used, any decrease of resistance in the outer circuit acts in the same way as putting more resistance into the shunt circuit, and thus tends to approach the unstable equilibrium point, whereas when using those machines, requiring practically no lead

* The required difference of E M.F. to obtain the best charging current varies with the cells employed.

† Messrs. Siemens' method of describing their conductors is the number of yards to 0·1 ohm. It is safe to pass the same number of amperes as the number of the conductor for short periods, and half its number for continuous working.

‡ This illustration must not be taken as expressing any opinion on the relative value of the dynamos, but only to indicate the action of each type when employed with an accumulator.

* If more resistance is inserted, then the dynamo runs as a motor, and no longer works as a generator.

Digitized by Google

for the brushes, the outer circle may be supplied almost indefinitely (within the capacity of the machine) from the dynamo, charging the accumulator at nearly the same rate all the time.

The author finds that with a Marshall steam engine, fitted with Hartnell's governor, the fluctuations of E.M.F. (standard 100 volts) make but an increased flow of two to three amperes to the cells when the dynamo (Siemens SD_2 or SSD_{10}) is set to charge the accumulator at the same time as supplying the lamp circuit, adjusted by means of the shunt resistance to near balancing point; and further, the nearest approach to unstable equilibrium, so as to work the lamps from the dynamo only, is that of passing three to five amperes to the cells—that is to say, if further resistance is put into the dynamo shunt circuit, at any moment unstable equilibrium ensues, due to the slight irregularity of the steam engine. Hence the rise of E.M.F. is limited to 1 per cent. at the terminals of the dynamo. Many experiments tend to show that in a well-arranged installation, where a gas engine is in use, the E.M.F. at the terminals of the dynamo need not vary more than ± 2 volts, and for steam engine ± 0·5 volt, these values being measured with no accumulator in circuit.

In order better to understand how the dynamo can charge the accumulator at various rates, and work to the lamp circuit at the same time, without injury to the lamps, it must be explained that one of the lamp mains must be capable of being connected (in a 100-volt installation) to the 45th cell during the time that the cells are being charged at the rate of 30 amperes, because 45 cells give 90 to 92 volts, and 10 per cent. more at the time of maximum charging, namely 99 to 101 volts. Again, if the charging is carried on at a lower rate, the lead mentioned must be switched to the 46th or some other cell till, at balancing point, the 49th or 50th is reached. Complicated as this method may appear, nothing can be simpler in practice.

It must be observed that, when charging 50 cells, and one of the lines taken off the 45th cell, the remaining five act as a counter resistance in the lamp circuit, and these have to pass the total current given by the dynamo. The evil effects of so large a current often flowing through them may be prevented in many ways, such as by creating a shunt to these cells, or having the five cells larger, so as to pass more current, or by coupling these extra cells with an equal number of the others in parallel, &c.

There is another way of looking at an installation worked with an accumulator. Let the lamp circuit be regarded, as a whole, as a variable resistance, and the accumulator as a nearly constant resistance. Then in reality the installation consists of a constant resistance with a variable shunt resistance (viz., the lamps). This is possibly a new view of the case, and a very convenient one for solving problems.

(5) That the total capacity of any installation equals approximately the total current which may safely be taken from the cells, together with an equal current from the dynamo, if dynamos having but little lead for the brushes are excluded.

This conclusion dictates conclusively the maximum size of dynamo, in point of economy, required in such installations.

(6) That the results here detailed may lead to many modifications in dynamos, by employing some form of counter E.M.F. regulator, instead of aiming at regulation in the machine itself, as done at present. The advantage of using this regulator will be that the machine can be made far simpler, with very few coils in the armature, and few plates in the commutator, and if massive soft iron field magnets are employed there will be no sparking; hence a very simple machine might come into use, with good efficiency, and wound in the simplest way, capable of being used as a direct lighting machine with very good regulation, or for charging accumulators by switching on the cells in the place of the counter E.M.F. regulator.

(7) That the size of accumulator to be used in any particular installation depends on the class of dynamo used, for if its E.M.F. rises rapidly for a decreased flow of current to the outer circuit, then clearly the accumulator may be of smaller size than when the reverse is the case, so that a small accumulator will serve to regulate a large installation if the dynamo is made suitable—that is to say, what would be called a badly regulating dynamo under some circumstances would here be the best machine. Further, the accumulator must be of very large size, if to regulate at all, with dynamos requiring a very small lead for the brushes. In all cases the resistance of the cells must be small compared with that of the lamp circuit.

(8) That as a general conclusion from the above—

(i.) If dynamos requiring much lead are used, steadiness of light is secured; but it must be observed that the lamps will get a little brighter as the "run" proceeds if the current flowing to the lamp circuit remains unaltered, because the counter E.M.F. of the cells increases as the charging advances, so that the total current given by the dynamo decreases, and the E.M.F. consequently has a permanent rise.

(ii.) With dynamos having but a very small lead, the E.M.F. in the lamp circuit remains constant at all periods of the charging, except at those moments when the speed of the machine is irregular and these variations at the terminals of the dynamo are much reduced at the lamps.

(iii.) Lastly, if a dynamo as in case (i.) is employed, and a dynamo or motor regulator is used, both defects above mentioned are overcome.

The following is a method for ascertaining what size of accumulator should be chosen for any particular installation:—

Let R = resistance of cells;
" nR = resistance of lamp circuit;
" a = *momentary* variation of E.M.F. above the normal, owing to irregularity in speed;
" E = normal E.M.F.

Then, if the dynamo is a suitable one, all *momentary* fall of E.M.F. below the normal will be compensated for, and the *momentary* rise of E.M.F. is all that has to be neutralised at the lamps.

Hence, the rise of E.M.F. at the lamps will never exceed

$$\frac{R}{nR} \times a = \frac{a}{n},$$

and the limits of E.M.F. will lie between E and $E + \frac{a}{n}$.

Thus, if a is large, n must be large, or else $\frac{a}{n}$ has a large value, for it is required that $\frac{a}{n}$ shall be made as small as possible.

In all installations the value of a can be ascertained, so that n has to be found. It must then be decided as to how small a variation of E.M.F. is to be allowed at the lamps, and the latitude will depend upon what the light is to be used for; this point settled, the value to be given to n is known.

To find what amount of lead a dynamo should have in any given installation,

Consider only the fall in the speed;

Let k = a constant expressing the percentage of *momentary* fall in the normal speed of engine when not working regularly.

Now, the E.M.F. varies very nearly direct in proportion to the speed, when these are compared at rates not differing much from one another.

Then the varying E.M.F. below the normal may also be expressed by k; hence, to keep the current flowing to the cells *momentarily* constant for the decreased speed, the E.M.F. should be made to rise a percentage equal to k, and this can be accomplished in the construction of the dynamo.

For the lead of the brushes may vary 90°, which may be interpreted that at 0° the E.M.F. is constant for all values of the current flowing to the outer circuit, speed remaining constant, and close to 90° for a very small difference in the quantity of current taken off, an immense difference in the E.M.F. would follow. The lead can never actually be made to exist at 0° or at 90°, but at any point between. And the *lead* and *rise in the E.M.F.* for a decreased flow of current in the outer circuit vary directly with one another, when compared at close intervals of variations hence the *extra lead* required to keep the E.M.F. constant at the lamps for any *momentary* fall in current flowing to the outside circuit due to irregularity in the engine is $k \times 90°$. If the usual current given by the dynamo requires a lead of $g \times 90°$, then for this machine to work with cells in any given installation the lead must be made $(g+k)$ 90°. From this it is seen that g may be made as small as desired, or variable, but k depends on the character of the installation. It may be noticed that $k = a$ in the last investigation.

To obtain the required *extra lead* $k \times 90°$,

Let n = polarity of the armature;
" m = polarity of field magnets;
" p = angle of lead;

Then $\frac{n}{m} = \sin. p.$

In the case under consideration, p being known, namely $(g+k)$ 90°, the relation $\frac{n}{m}$ may be arranged as most convenient.

Returning to a 100-volt installation (50 lamps 20 candle-power) with a gas-engine, if we have $n = 20$ and $a = 2$, then the E.M.F. at the lamps will vary from 100 to 100·1 volts; and if a steam-engine replaces the gas-engine, and $n = 20$ and $a = 0·5$, then the E.M.F. will only vary from 100 to 100·025 volts. Lastly, if it is allowed to vary the E.M.F. as much, say, as one per cent., many combinations may be employed, from a very irregular motor to a very small accumulator. Also the *extra lead* will in the first case be 1·8°, and in the second one 0·045°.

COMPANIES' MEETINGS.

The Australasian Electric Light, Power, and Storage Company (Limited).

An extraordinary general meeting of the shareholders of this Company was held at the offices, 41, Coleman-street, on the 10th inst., under the presidency of Mr. Latimer Clark.

The SECRETARY (Mr. J. H. Duncan) read the notice calling the meeting.

The CHAIRMAN stated that they had met that day to adopt the report of the Directors and accounts, and to consider the report of the committee appointed at the meeting on the 30th December to confer with the Directors as to the past history and present prospects of the undertaking. The committee issued their report on the 21st of February, the Directors sent out a circular on the 26th of February and a sort of reply on the 4th of March. That committee was formed in pursuance of a suggestion by the Directors in the report, which they were, he hoped, going to adopt that day. They stated in their report that they would "welcome the appointment either of another nominee of the shareholders (preferably a large holder of original shares) to join the Board or of a small committee of consulting shareholders to advise in the place of Mr. Hammond." The committee was formed in consequence of the action of several shareholders at previous meetings, who had expressed themselves very much dissatisfied with the results obtained or with the management of the Company. The committee was formed and had now given in their report. The gentlemen forming the committee were chosen from amongst those who spoke in the

Digitized by Google

most hostile manner at the last meeting, and therefore the Directors could not be accused of any partiality or attempt to pack the committee. The Directors were not unconscious that they had the support of the large body of shareholders when they allowed the committee to be formed, and the majority of hands held up in favour of the committee was extremely small, the numbers being 11 for it and 9 against it. The Directors themselves did not vote. The result had been what the shareholders saw. They had been somewhat blamed for the course which they took by some large shareholders, who had said that the interests of the Company would not be served by the public washing of their dirty linen, and that the Directors had been wrong in bringing into existence such a committee. Perhaps, had the Board foreseen all that they now knew, they would have been wiser had they held up their hands and prevented the formation of the committee. But they felt when their honour was in question that it was their duty to create the committee. They were very much gratified that it had been called into existence on one account, namely, that it had enabled all the shareholders to see that there had not been at any rate any wilful wrong doing. Unfortunately the report of the committee had found its way into some of the newspapers, and had caused some little inquiry among those with whom the Company had financial and other dealings, and it would no doubt get into the colonies, and must do the Company harm. He hoped, however, that at that meeting the good done would counterbalance this harm. The committee having had full access to documents, and having read them as far as they were able, did not communicate to the Directors the opinions and views they had formed. If they had done so the Directors had no doubt that many of the views formed by the committee would have been very much modified and changed. They were perfectly unable in the time they devoted to the subject to read he might say any of the correspondence on which all the actions of the Board had been based. They were compelled to take merely the minutes, and to form their opinion upon them. They were justified in doing so, but they had naturally fallen into error, as any of them would do who formed their views merely from a rather cursory investigation that a reading of the minutes would give. The committee had declined to let the Directors know what their conclusions were; and as they sent out their report to the shareholders without letting the Directors see what it was, they had no alternative but to make a reply such as they could in a brief way, and that was the situation they had now to deal with. The report of the committee really practically contained one recommendation, which was that the Directors should resign as a body. He regretted to inform those who wished the Directors to resign that they did not see their way to do so, and the large body of the shareholders were of the same opinion as the Directors. Proxies had been sent out and returned, and they showed an overwhelming balance of opinion in favour of the Directors retaining their seats. They had received some 10,000 proxies in favour of their continuing as they had done, and about ten in favour of their retirement. There was one other recommendation made in the report, which had reference to the Directors' fees, but those two were the only real practical suggestions made in the report. The rest consisted rather of animadversions on the past management of the Directors. As to the latter matter they had never failed to admit that they had made the greatest blunders, the fact being that they had all been carried away—the shareholders as well as the Directors—by the enthusiasm and mania which formerly existed as to the electric light. He knew nothing like that event since the days of the South Sea bubble. It was difficult now to realise it. But he might mention one fact. After Sir Julius Vogel left some responsible gentlemen came to the Board and offered them £20,000 for the right of their patents in New Zealand. Shareholders would suppose that the Directors would have accepted this offer, but they politely bowed those gentlemen out of the room. They were also asked to put prices on their patents, and they did so at figures which now looked fabulous. Those circumstances, however, showed that they were not acting under the same cool judgment and knowledge of the facts as they now were. As to their fees, they were asked by the committee to strike out the sum which stood to their credit in the profit and loss account, but they had stated that they would never take that money unless the Company were earning a dividend. They resented being dictated to by the committee on this point, and they declined to do more than say what they had said before—that they would never take that money unless the Company were earning a dividend; and even if it were earning a dividend they would be quite prepared to, and would, reduce that amonnt. Their great object at the present moment was to avoid a call, and those gentlemen who would get up presently and address the meeting should, he thought, avoid saying anything to damage the interests of the Company in future. He was happy to say that the tide had now somewhat turned. They had promises now of remittances from Australia, and they had negotiations going on for large and new contracts there which he hoped might come to fruit; and therefore he looked with some pleasure to the future. Before sitting down he would wish to refer to a personal matter. The committee had expressed surprise that he should have allowed himself to be placed in a position of a dual character. But in that they were somewhat mistaken. There was nothing of the kind in the matter. The interests of the firm which he represented and of the Company were identical. No profit could be made by one without a profit to the other. It was true that there was afterwards disagreement as to this arrangement made between the Company and his firm, and that the Directors had wished to terminate the arrangement. When that occurred he was in a dual position, but it was one he could not have foreseen, and he gave every assistance in the closing of that negotiation. Moreover, he took no part whatever in the discussions on the subject at the Board.

Mr. WAINWRIGHT, who stated that he represented not only himself but other shareholders, complained of the £500 a year which was paid for offices and clerks. As to the proxies, they all knew that this was the most objectionable form of voting in the City of London, because people who voted by proxy knew nothing of what was going on in connection with the management of the Company. In the case of similar companies, the Directors had seen that the proper course was to wind up, and there was no doubt this Company ought to have been wound up two years ago. He expressed his intention of voting for a change in the management.

Mr. T. B. WILLIAMS asked the approximate profit on the work which had been mentioned by the Chairman.

The CHAIRMAN stated that there were objections to giving the information, as they had rivals. He then formally moved the adoption of the report and accounts.

Mr. CATER seconded the motion.

A SHAREHOLDER thought that six Directors in London were unnecessary, seeing that the whole paraphernalia connected with the management was in the colonies. He thought that there should be only half the number, and that the Directors should forego their fees. He would also like to ask if there were any number of men in the City who could justify the sending out to Australia of Sir Julius Vogel at ten guineas a day. In his opinion the Chairman had not upset a single word of the report of the committee.

Mr. BENJAMIN KISCH (of the committee) said he was glad to see from the general feeling of the meeting that they had been convinced of their own accord that all the conclusions of the committee were perfectly justified, and they had not been rebutted in any way by the reply which had been issued by the Directors. The committee had conducted their inquiry throughout without any feeling of animus towards the Board, acting merely in regard to the pecuniary interests of themselves and of the shareholders, whose interests were identical. As to what the Chairman had said, that the committee in some respects had not carried out their mandate, a reference to the original resolution appointing them would show that by its terms they were "to report to a further meeting of shareholders," not to the Board, and they therefore had thought it their duty to report directly to the shareholders. They had been a little reproached for not discussing other matters with the Board, but as regarded the future they were in the hands of the Board as to what matters should be discussed. They did not know beyond what the Directors told them what the Board were doing or contemplating. As to the past, they did not feel that they were warranted in occupying their time. However, wherever they had been in doubt they had consulted the secretary, and in fact the Board through that gentleman. But that was to set themselves right as to facts, and he submitted in the result that they had all their facts correct. The Chairman had referred to the large number of proxies which the Board had received, and the small number the committee had received. No doubt that was the case. But the committee had not wished to enter into a contest with the Board, feeling that that would have been against the interests of the shareholders. He might say that the vendors of the Company received between them 6,000 shares credited as fully paid up, and he need not say that all the votes attaching to those shares were included in the Directors' proxies.

The SECRETARY: That is not the fact.

Mr. KISCH: Well, almost all. Continuing, he said that he saw in the list of proxies a large number of vendors' shares, even those which were intended, according to the statement before them, to be surrendered. Sir Julius Vogel's 1,552 shares were put down on the list of proxies, and a vast number of others; and one of his colleagues reminded him that there were about 600 shareholders, and about 49 on the list of proxies. He desired to state that they had no intention of entering into a contest with the Board, but, what was much fairer, to judge of their support by the independent action of the shareholders in the room. He then went through the report which had been issued by the committee, as it had been stated by the Directors that there were certain erroneous conclusions on many points. In the course of his remarks he referred to and criticised the terms of Sir Julius Vogel's appointment, and maintained the accuracy of the remarks of the committee as to the New Zealand Company. As to the accumulator option, the Directors in their reply had stated that "the purchase was carried through after long discussion, and with the utmost circumspection, the payment over of the money being left absolutely in the hands of the Company's solicitor." The Company's former solicitor was present, and would no doubt give his version of the matter. Having alluded to other points dealt with in their report, he asserted that in no material respect had any of their conclusions been successfully impugned. As to the question of the Directors' fees, he did not think the shareholders would be satisfied with what the Chairman had said, for if the matter remained in that way the suspense account would go running on from the 30th of June last at the rate of £1,000 a year. Seeing what the Directors had done so far, he did not think it was too much to ask that those undrawn fees should be waived. They did not bring forward any resolution of their own, but left the matter in the hands of the meeting.

Mr. FRANCIS INCE stated that he was unfortunately one of the largest shareholders of the Company, and also o iginally the solicitor of the Company. He felt bound to make one or two remarks as to the accumulator option, the position of which was to a certain extent a simple one, so far as the Company was concerned. At a Board meeting Sir Julius Vogel came into the room and told the Directors he had secured the option of the purchase of the Sellon-Volckmar patents up to four o'clock that day, if the sum of £5,000 was paid, the option extending for a year. The Directors then requested Sir Julius Vogul to attend at four o'clock with the solicitor to the vendor company and himself (Mr. Ince), and to see the solicitor to the Sellon-Volckmar Company and ascertain whether an agreement for the purchase of the patents with the option of purchase for a year could be entered into, and practically his (the speaker's) instructions at the time were to part with the £5,000 almost on any terms, in order to secure the option, because the Board believed it would be a very valuable patent to secure. He received his instructions as solicitor of the Company, without any respect to any electrical knowledge he might possess. He believed at the

Digitized by Google

time that the arrangements were proposed to be made as to the Sellon-Volckmar option that the Sellon-Volckmar patents were practically worth very little. There was a clause in the agreement that was sufficiently clear to have entitled the Company to recover back the £5,000, and his view of that clause was agreed to by Mr. A. L. Smith, now Mr. Justice Smith, who was his counsel, and who advised that the money could be recovered; and the reason the action failed was that the Directors of this Company were not aware of prior negotiations that had taken place between Sir Julius Vogel and Sir Daniel Cooper, one of the Directors of the Sellon-Volckmar Company, of which neither he nor the Directors were aware. Again, Sir Julius Vogel was sent to act in good faith with Mr. Trinder and himself before parting with the £5,000; but it was not known to the Company nor to him that Sir Julius had stipulated that on any amount this Company might pay he would receive a commission of 10 per cent. If he (Mr. Ince) had known for a moment that such a stipulation had been made he would have told Sir Julius Vogel that he would have been no party to paying over this money—that he could not advise the Company to part with the money, and he would have told Sir Julius Vogel in language very plain what he thought of him. He had no doubt that the Directors believed, as he did when he reported the terms of the draft agreement, that they would be able to recover the money, and so they would had all the circumstances of the case been known to them at the time, and were as they believed them to be, and not as Sir Julius Vogel knew them to be.

Mr. FREDERICK ROBERTS asked whether Sir Julius Vogel could not be sued for the £5,000 if he had acted as the Company's agent in connection with this option, and had yet stipulated with the other side that he should have a commission. If that were so, he would have acted in a dual capacity.

Mr. PHILIP FALK (a director) argued that the Directors, after all, were not to be blamed in the way that the committee had suggested. He had been interested in Australasian business for thirty-five years, and received a great deal of information from people carrying on business both in Melbourne and Adelaide. He had held his shares and he felt that the time had arrived when they were going to turn the corner. When the third call was about to be made some of the Board took into their most serious consideration whether the time had not arrived for them to go into voluntary liquidation. But such were the statements of business put before them that they could not undertake the responsibility of such a step. He maintained that the committee were now in the very self-same position that the Directors were in two years ago, for they had themselves shrunk from saying that the Company should wind up.

Mr. INCE stated that the committee did not advise winding up, but they would have done so if they could have seen their way. If they wound up, the first thing a liquidator would have to do was to make the last call, in order to make the shares all paid up, and in that case the vendors would get more of the shareholders' money. He had omitted to speak about the Directors' fees. The Chairman had said that they were not going to ask for the fees until a dividend came in the future. But there was another reason. Those fees were put to a suspense account because if there was a winding-up the Board would have a claim against the assets, and ask for payment of every shilling of the money. The Board had admitted that they had made great mistakes in the past, and if that were so, was it not right, equitable, and just that the Directors should give up all claim to the fees in question?

A SHAREHOLDER asked whether the Directors were willing to retire.

Mr. M'LEAN asked the Directors to make a clean breast of all they knew about Sir Julius Vogel.

Mr. R. E. STEVENS thought they might let Sir Julius Vogel off, as he had surrendered his shares, and he did not believe they would get anything more out of him. With regard to what the Chairman had said about their voluntarily inviting the appointment of a commitee, he maintained that it was a matter of Hobson's choice with them.

Mr. THOS. PEARSON and Mr. LYALL having spoken, the latter gentleman maintaining that the arrangements with Sir Julius Vogel were most preposterous,

Mr. ROBERTSON asked if the Directors retired whether there was anybody else to take their place. He thought, as a small shareholder, that though the Board had made mistakes it was for them to pull the Company out of its difficulties. He thought the report of the committee had told them nothing beyond what they knew.

Mr. B. H. VAN TROMP, in answer to a shareholder, said that he could add nothing to what had already been said by other members of the committee. He was distinctly of opinion that it was not necessary, on account of what was stated in the report, and also on account of what Mr. Ince had said, that they should go into voluntary liquidation at the present moment, because if they did every shilling of the money would be lost, and it was better to go on to the end in the hope and expectation, and, he thought, the reasonable possibility of a great improvement in Australia with regard to electric lighting. He was prepared to do exactly what the meeting wished, to act with the present Directors, of whom he was now one, or with any fresh gentlemen whom they might appoint.

The CHAIRMAN, at the close of the discussion, replied, and stated that there had been a general inclination on the part of every one to mix up all the early mistakes made by the Board, which they had frankly admitted, and to assume that all those mistakes were still going on as before. He believed that Mr. Van Tromp would tell them that the Directors were now, and had been for twelve, sixteen, or eighteen months before his accession to the directorate, aware of their mistakes, and had entirely altered their policy. They had reduced the expenditure, and were still continuing in the same direction, and would bring the expenditure down to the utmost possible limit. There had been a strong feeling expressed against their continuing in office, but he wished to say that if they resigned someone must take their place, and he had no doubt that many gentleman would be quite willing to do so, and competent to a certain extent, but they would not have the advantage of the long previous knowledge of the Directors. Again, the Directors had to represent not merely a portion of the Company, but the whole of the shareholders of the Company. He had carefully noted down the speakers, and the total number of shares held by those in favour and those against them was extremely small compared with the generality of the shareholders. They were certainly not disposed to resign their seats. As to their fees, they had been disposed to deal liberally with the shareholders in the matter, and he believed they had done so. But at the present moment he did not feel that they would give way before the pressure which had been brought to bear upon them. Sir Julius Vogel took himself 250 shares, and he received 1,542 vendors' shares from the Company for forming the Company. The vendors' shares he had given up.

A SHAREHOLDER: Can the Secretary tell us how many golden sovereigns Sir Julius Vogel had?

The SECRETARY said that he believed Sir Julius Vogel had received 1,542 shares in this Company as his repartition of vendors' profits. £45,000 was paid for the patents in cash and £30,000 in shares. As a matter of fact he believed that each of the vendors had £30 or £40 and their shares. The profit of the vendors was in shares. [A Voice: "They sold their shares at a premium."] He believed none of the vendors had sold their shares with one exception, and he (the Secretary) was himself the purchaser of those shares.

The CHAIRMAN then put the resolution to the meeting, and declared that the show of hands was distinctly against it, but as the number of votes was in favour of the Directors he declared the resolution carried.

Mr. INCE said that he would demand a poll unless the Directors gave way and consented to forego their fees.

The CHAIRMAN again declined to accede to this request, and a poll was accordingly demanded, which it was arranged should be taken on Monday next, between the hours of eleven and two o'clock, at the office of the Company.

A resolution was afterwards passed voting £100 to the committee in recognition of their services, and the proceedings then terminated.

NOTES.

CABLE INTERRUPTION.—The cable between Maranham and Para is interrupted.

COMMUNICATION WITH PARAGUAY.—Telegraphic communication has been established with Paraguay in South America.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the weeks ended 6th and 13th March amounted to £3,543 and £2,690 respectively.

NOTICES OF REPAIR.—The cable between India and Ceylon is repaired. The cable between Trinidad and Demerara is also repaired, and telegraphic communication is therefore restored with British Guiana.

ELECTRIC LIGHTING AT LLOYD'S.—The lighting of the hoist is now done electrically by means of E. P. S. accumulators. A set of cells will supply the current for about a fortnight, working 10 hours a day, after which the cells are replaced by another set fully charged.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the weeks ending 6th and 13th March were £2,845 and £2,072, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

NEW BOOK.—We have received "A Collection of Examples on Heat and Electricity," by H. H. Turner, B.A., Trinity College. The work, which is published by Macmillan and Co., deals with abstruse mathematical problems presented in the study of heat and electricity.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th March are £2,925, as compared with £2,770 in the corresponding period of 1884. The December receipts, estimated at £4,468, realised £4,619.

THE SUAKIN-TRINKITAT CABLE.—In our issue of the 14th inst we announced that this cable would probably be completed and at work by the 18th inst. The steamship "Chiltern" has arrived at Suakin with the cable on board, but in all probability will await the orders of the Commander-in-Chief before proceeding with the work.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—A meeting of this society will be held at 25, Great George-street, Westminster, S.W., on Thursday, 26th inst., when there will be read the paper now appearing in *The Electrician*, on the "Seat of Electromotive force in a Voltaic Cell," by Professor Oliver J. Lodge, D.Sc.

QUADRUPLEX WORKING.—The electrician of the Wheatstone department in New York has devised a plan for quadruplexing the wires assigned to the Wheatsone system and utilising the neutral side for Morse working. As now arranged the wires are operated upon the duplex method, and the improvement would be in effect a gain of two wires. The trial tests of the apparatus have given favourable results.

LIGHTING OF THE SENATE CHAMBER AT WASHINGTON, U.S.A.—The Edison Company have successfully made the experiment of lighting the Senate Chamber and lobbies at Washington. It is said that the funds necessary for a complete installation in that wing of the Capitol will at once be appropriated; the lighting of the House end of the buildings remaining in abeyance until the result of more extended experiments is known.

FOREIGN EXHIBITIONS.—As announced in our last issue, the opening of the Electrical Exhibition in Paris will take place to-morrow. The inauguration, at which the President of the Republic will assist, is fixed for to-day (Saturday). Prices of admission to the Antwerp Exhibition, which is to be held on the 2nd of May next, have been arranged as follows:—For each person, between the hours of 8 and 10 a.m., 2 francs; after 10 a.m., 1 franc only.

THE TELEPHONE AND THE NEWSPAPERS.—Messrs. Horncastle and Co., advertising agents, of Cheapside, E.C., received on the 17th inst., direct by telephone from Brighton, the actual words and instructions respecting insertion of an advertisement in a daily paper of the 18th inst. The whole transaction only occupied a couple of minutes. This is, we (*City Press*) believe, the first practical use of the telephone for newspaper purposes over so long a distance.

THE GLOBE TELEGRAPH AND TRUST COMPANY.—The directors at the Board meeting, held on the 17th inst., declared the payment of an interim dividend on and after the 20th April of 3s. per share on the preference shares, less income tax, and 2s. per share on the ordinary shares (income tax having already been deducted) for the quarter ending the 18th April, 1885. The transfer books were ordered to be closed from the 13th April to the 20th, both days inclusive.

THE REBELLION IN CENTRAL AMERICA.—The Central and South American Telegraph Company has notified the authorities in Mexico, San Salvador, and Nicaragua that guards have been posted at the cable landings in order to protect them. Mr. Bayard, Secretary of State, has telegraphed to the American Legation in Guatemala, declaring that the United States will hold Guatemala responsible for any injuries to the cables or to American interests caused by her authority or with her connivance.

THE POST OFFICE TELEGRAPHS.—The gross amounts received and expended in respect of the telegraphic service from the date of the transfer of the telegraphs to the State to 31st March, 1884, are stated to be as follow:—The gross amount received for telegrams in that period was £18,225,778, and the amount expended in the working of the department was £16,662,347, and £2,395,082 remained as a balance to meet interest on stock created on account of the telegraph service and the redemption of debt.

THE TELEPHONE IN PARIS.—A GOOD IDEA.—On the 15th inst. there were first issued to the public of Paris a number of telephone tickets, at 50 centimes each. These tickets may be presented at any of the Paris post offices, and entitle the owner to hold five minutes' conversation with persons in any other post office or at any of the Telephone Company's stations. The Telephone Company offers, at the same rate, conversations at any of their eleven stations with persons at any other station or at the residence of any of their subscribers.

THE TELEPHONE IN PARIS.—The Society of Ambulances in Paris have nominated a committee, presided over by M. Jules Simon, for the purpose of determining the best means of securing prompt medical assistance in cases of accident in the public highways. It has been decided by the committee to establish telephonic communication between the chemists and druggists and the hospitals in various quarters of the town. By this means the nature of the accident and of the remedies or assistance required for its relief can at once be indicated.

NEW CATALOGUE.—We are in receipt of the new illustrated catalogue of telegraph materials, electrical instruments, and other apparatus manufactured by Messrs. Latimer Clark, Muirhead, and Co. In addition to a description of almost

Digitized by Google

every electrical appliance known to the world, and some valuable hints as to the application of galvanometers, &c., to telegraphic and experimental purposes, the catalogue contains a variety of useful tables and formulæ, treating of units, resistance, temperature, and other matters of interest to the electrician.

SS. "ELECTRA."—The directors of the Eastern Telegraph Company on Thursday invited a number of gentlemen to inspect the new ship "Electra," now lying in the South West India Dock, previous to its departure to Souakin. The ship was agreed on all sides to be an exceedingly fine specimen of what a cable ship should be. The ship is under the command of Captain Pattison, and Mr. Kennelley is in charge electrically. Cable and stores are being rapidly taken on board, and it is expected that the ship will leave about Tuesday next for her destination.

ELECTRIC LIGHTING AT MESSRS. H. J. NICOLL AND SONS, REGENT-STREET.—This firm was amongst the first to adopt the electric light, having used arc lights on the Jablochkoff system for some years past. As, however, some incandescent lighting was required in addition to another arc lamp, it was decided to utilise the existing gas engine to charge accumulators during the day. The arc and incandescent lamps are supplied from a set of the Electrical Power Storage Company's accumulators, and the arrangement gives every satisfaction. The remarkable steadiness of the Brush ratchet lamp when supplied by accumulators may be noticed by any one passing Messrs. Nicoll's at night.

THE TELEPHONE IN BRISTOL.—The Western Counties and South Wales Telephone Company have taken over the business of the United Telephone Company in this district, and have undertaken all existing agreements and arrangements entered into by the latter company. To show one of the uses to which the telephone may be put in a large city like Bristol, it may be mentioned that a fire recently broke out in Southwell-street, Kingsdown, contiguous to the premises of Mr. E. F. Woodward, sanitary engineer, a subscriber to the Telephone Exchange. That gentleman at once telephoned to the central fire station, and in seven minutes a policeman from the Central Police Station appeared on the scene and turned on the water at the street main. In nine minutes the fire brigade were on the spot at work, and the conflagration was stopped before it had time to spread.

THE ELECTRIC LIGHT AT SAINT ETIENNE.—The town of Saint Etienne will, it is said, be the first to possess a central station for electric lighting purposes in France. The arrangements have been completed, and the necessary works already entered upon. The installation, which will be laid down by the Edison Company, will be upon the American model, comprising 3,000 incandescent lamps of 8 and 16 candle-power, and 5 A dynamos for 500 lamps each, with one spare dynamo. These will be driven by four engines of 70 horse-power. The station, placed in the centre of Saint Etienne, will furnish the light for the quarter of the Hotel de Ville, and the number of persons who have tendered their subscriptions for a period of five years is even now considerable. The *cafés*, the theatres, &c., situated in the quarter have all adopted the new luminant. The work, we are informed, will be finished about September.

THE ELECTRIC LIGHT FOR THE SOUDAN.—The electric light and other plant ordered by the Government for the Soudan, as announced in our issue of the 14th, consists of the following :—Six sets of apparatus, by Brotherhood, for 6-1,000-candle lights, with six spare lamps, and three spare lanterns to work on 4ft. 8½in. gauge, trolleys and shears, crabs, ropes and brackets, 500 yards of cable, all complete for lamps, 4,000ft. carbons, wrought-iron dust-proof case with each set. Six sets of ditto, by Kitson and Co. (fitted on trolleys 4ft. 8½in. gauge), each of six lights (Brush), and 800 yards of cable, with lamps, lanterns, carbons for 2,000 hours each lamp, poles, crabs, and appliances for lamps complete. In addition to this there will be for early shipment to Suakin six sets of Siemens' telegraphic apparatus (five miles in each set), with alphabetical instruments and telephones complete, two spare sets of telegraph and four spare sets of telephone instruments.

UNITED TELEPHONE COMPANY.—In order to increase the usefulness of the exchange system throughout the metropolis, the Directors of the United Telephone Company have announced that the London exchanges are now open from 9 a.m. to 9 p.m., instead of from 9 a.m. to 7 p.m., as hitherto. During the Session of Parliament, and until further notice, the West-end exchanges will be open all night—that is, there will be a continuous service at these exchanges by day and by night. The directors have further arranged to connect the exchanges with the Central Telegraph Office in St. Martin's-le-Grand, and all subscribers to the company's system will be able, from their own offices, to transmit and receive telegrams direct through St. Martin's-le-Grand on arranging for payment of the ordinary tariff charged by the Post Office for the transmission of inland and foreign messages. This service will be opened in the beginning of next month, and the United Telephone Company will not make any extra charge for the increased facility thus afforded by the telephone.

LA SOCIETE INTERNATIONALE DES ELECTRICIENS.—The order of the papers to be read at the Conferences of the Society in Paris during the coming week is as follows :—On Sunday, the 22nd inst., at 9 p.m., "Applications of Electricity to Astronomical Observations," by M. C. Wolf, member; March 23, at 8:30 p.m., "Telephony," by M. L. Maiche, electrician; March 23, at 9:30 p.m., "Telephonic Induction," by M. C. Elsasser; March 24, at 9 p.m., "The Electric Light-houses," by M. A. De Méritens; March 25, at 8:30 p.m., "Accumulation and Transformation of Voltaic Electricity," upon the experiments of M. G. Planté, by M. P. Samuel; March 25, at 9:30 p.m., "Applications of Electricity to the Military Art," by M. Le Roux; March 26, at 9 p.m., "Applications of Electricity to Medicine," by M. le Docteur Boudet de Paris; March 26, at 8:30 p.m., "Galvanometric Measuring Apparatus," by M. G. Lippmann; March 27, at 9:30 p.m., "Applications of Electricity to Railways," by M. P. Jousselin; March 28, 9 p.m., "Electric Transport with regard to the Automatic Distributions under Different Forms of Energy," by M. G. Cabanellas; March 29, at 3 p.m., "Applications of Electricity to Weather Forecasts," by M. le Dr. Marié-Davy; March 29, at 9 p.m., "Telegraphy," by M. E. Baudot.

THE NEW MAXIM ELECTRICAL TRAINING GEAR FOR HEAVY ORDNANCE.—The new electrical training gear, described in a recent issue of the *Pall Mall Gazette*, is one of the most important innovations of our day; and is, perhaps, destined to revolutionise the principles which at present govern the training and adjustment of modern ordnance. Mr. W. H. Massey has lately made some very exhaustive experiments with the apparatus, which, it appears, is so contrived that by the movement of a handle the breech of the gun can be moved to the right or left, and the muzzle raised or depressed, as may be desired. Mr. Massey speaks very highly as to the efficiency of its action. The small switch con-

Digitized by Google

trolling the speed of the two motors (which may be run together in the same or in opposite directions, or independently of each other in either direction) is a most ingenious piece of mechanism; the movement of the handle making the necessary connections with the motors and also cutting out resistance as it is pushed in the direction in which the breech of the gun is intended to be moved. The gear was applied a few days ago to one of the 38-ton guns at Garrison Point Fort, Sheerness, and it was then shown that one man could train the gun with perfect ease and accuracy. Altogether the thing promises to be a great success, and we trust that Mr. Massey will receive a reward commensurate with his exertions.

ELECTRIC LIGHTING CONVENTION IN CHICAGO.—The first convention of the representatives of the electric lighting interests of the United States commenced in Chicago on the 25th inst., and is well attended by representative men from all parts of the country. The committee on digest of papers and programme of business reported the following order of proceedings and topics for discussion:—1. Incandescent lights particularly in regard to length of circuit upon which they can be run with profit; 2. Locating and avoiding crosses with telephone wires; 3. Power and its conversion into light; 4. Electric light globes and shades; 5. The best modes of connecting dynamos with power; 6. Electric lighting by water power; 7. Rates and rebates on electric lights by the year; 8. The use of electricity as applied to motors; 9. Where an electric light system requires No. 6 conductor, is it desirable to use Nos. 6 and 4 in the same line? 10. Will armatures become affected by frost when exposed in transportation? 11. Special insulation or guards to insulation of lines at dangerous points and places; 12. Street lighting—the best manner and modes of accomplishment, embracing the location of lights and running of circuits; 13. Experience and results in the use of underground conductors; 14. *Resolved*, That the fireman should receive more pay than the engineer; 15. Help generally; 16. Experience of electric light companies in the use of copper-coated and uncoated carbons.

GREENWICH TELEGRAPHIC AND ELECTRICAL SCHOOL.—A new telegraphic school has been opened at the Lecture Hall, Royal Hill, Greenwich, with Mr. S. T. Dalton as the instructor in practical telegraphy, and Mr. A. P. Chattock, member of the Physical Society of London, as the theoretical instructor. In order to supply the requisite instruction and training to persons intending to follow the profession of telegraphy, classes have been instituted at the above school, where such persons may obtain a practical knowledge of the nature and construction of the instruments now in use, a thorough training in their manipulation and in the transmission of telegraphic messages, with a sufficient grounding in such branches of electrical science as bear upon the subject of telegraphy. The course of tuition includes instruction in the working of the Morse printer, the sounder, the single needle, the mirror, and the syphon recorder systems. Experimental instruction is also given in the fundamental laws of electricity and magnetism, in electrical testing, and in the various electrical measurements, and in such branches of mathematics and physics as are incidental thereto. In addition to this students are instructed in the principle and arrangement of the different instruments and systems used in telegraphy. Experience has proved that the most effectual method of acquiring proficiency in scientific knowledge is for the student to conduct his own experiments under the supervision of the teacher, as by this means the methods of experiment, arrangement of apparatus, &c., not only become impressed upon his mind, but he is able to pay special attention to those branches of the subject with which he is least acquainted. This principle has been adopted by the promoters of the new establishment.

BUILDING TRADES EXHIBITION. — This exhibition was opened in the Agricultural Hall, Islington, on Monday, the 16th inst., and will remain open until the 28th. As at several trade exhibitions held lately at this hall, there is an attempt—very good as far as it goes—at electric lighting. Messrs. Gretton, Mynn, and Co., of Grocers' Hall-court, E.C., supply several exhibitors with about 150 incandescent lamps of 20 actual candle-power. These are the Grubbe lamps, made by the Electric Manufacturing Company, and now exhibited for the first time. They are five inches long, with the carbon filament simply bent double without any coil or twist. The first two days they were maintained by a Gramme dynamo; but Grubbe and Benson machines were afterwards substituted, which are also to give current to a Phillips arc lamp, which is independent of springs and mechanism. It is a common fault with electrical indicators that the inefficient pivoting of the armature, or of the pin on which it plays, causes a sluggish action. This makes too great a demand upon the battery; and it frequently happens that the bell rings, while the visible signal is not made. Mr. George Porter, of Cullum-street, E.C., has overcome this difficulty in his patent indicator, by sending the current first through the electro-magnet working the visible signal, which, in falling, makes a contact, sending the current through the bell circuit. It is claimed that, with this arrangement, a battery of only half the usual power is required. He also shows in action a combined electric and pneumatic bell-call. The push works a piston in a small metallic tube, and forms electrical contact, sending the current through the electro-magnet, and causing the bell to ring as long as the finger is kept on the push. Messrs. Eck, Callow, and Co., of Dean-street, W.C., and Clerkenwell, exhibited, among a great variety of electrical appliances, a perfectly new electric lamp-lighter, independent of a battery and also of revolving mechanism. Two new gas engines are shown, in both of which there is an impulse at each revolution. One, vertical, designed by F. W. Turner, the father of the original Otto engine, has two slide valves for distributing the gas and igniting it, worked by separate excentrics, thus dispensing with springs and the objectionable catch levers formerly used, and ensuring a smooth and positive action of the valves. The 1 horse-power nominal, or 1½ actual, consumes only 45 cubic feet of gas per horse-power per hour, and the cylinder is kept cool by a stream of water, which affords a hot water supply. J. E. H. Andrew and Co., of London and Stockport, show their new horizontal "Stockport" engine, which has a separate cylinder for compressing the charge of gas and air before ignition.

THE ELECTRIC LIGHTING OF THE PADDINGTON STATION.—We extract the following from the *Journal of Gas Lighting, &c.*:—"The Telegraph Construction and Maintenance Company have paid 20 per cent. for the past year. This is an indication of the profit that is to be gathered from some branches of electrical work. In addition to their ordinary business, however, the latter company are doing something in electric lighting, upon the system designed by Mr. J. E. H. Gordon. They are laying down an installation for lighting the Paddington Station of the Great Western Railway Company—a work which the chairman (Sir Daniel Gooch), who happens to hold the same position in both the telegraph and the railway companies, confesses has 'taken much longer than he had expected.' Translated into unofficial language, this admission probably means also that it has cost more money than was anticipated. It was declared, however, that the lighting o

Digitized by Google

this railway station is only a gigantic experiment for enabling the company to obtain the necessary experience for undertaking the lighting, in a similar way, of the parish of St. James, for which the company hold a provisional order. At the shareholders' meeting a question was put across the table with the object of eliciting what the Board really think of their Paddington experiment; and the chairman boldly confessed that it would be a loss. He maintained, however, that the lighting would be a success, and that the cost of it would not be altogether wasted, since it would show the Board exactly how they stood in respect of a large undertaking. It might be supposed that after all the lighting of a railway station, however large, with all the offices, &c., under one roof, and a trained staff always at hand to see and correct everything that goes wrong, is not quite the same thing as the house-to-house lighting of a London district, even in a technical sense. Commercially, the difference is immense. At Paddington the full consumption may be entered upon directly the installation can be got to work. There will be no waiting for patronage, with machinery and plant capable of supplying 20,000 lamps constantly going to supply one-tenth of the number." As a matter of fact the installation referred to is little more than in projection. Nothing whatever is known about it, even by the electricians of the company themselves. Our contemporary is naturally anxious, in the interests of gas lighting, to pass strictures even upon what is palpably incomplete; and remorselessly takes advantage of the admission of Sir Daniel Gooch that the work might be conducted upon an experimental basis rather than a commercial one. The explanation, however, of our contemporary's animadversion is to be found in the uncertainty which surrounds this installation. It is not often that so favourable an opportunity occurs for speculative reasoning into which bias can enter without fear of immediate contradiction.

Laying First Rail of the Blackpool Electric Tramway.—The first rail of the Blackpool Electric Tramway was laid on the morning of the 12th inst. by Alderman M'Naughtan, who, having completed the task assigned to him, said he had great pleasure in laying the first rail of the Blackpool new tramways. It was fortunate for them that the matter had been delayed so long, for had the trams been laid years ago they might not have been in the splendid position which they occupied that day. They would probably have had either the ancient horses, or steam, and they were all perfectly aware of the dangers from accident which attended both of those means of propulsion. They had now been enabled to avail themselves of one of nature's most wonderful, immense, and mysterious agencies—electricity. He trusted that the adoption of electricity would be a great success, for if so, it would be an immense attraction to Blackpool. Mr. Holroyd Smith, the lessee and engineer, then explained the purpose of an "insulator," which he afterwards attached to the rails. As long as he lived, he said, he would remember that act, because he felt that it was an act of importance not only to him as an individual but to a large number of people whose confidence in himself had been manifested so strongly. The little act was important, because upon it hung strange issues, viz., this line when laid would be the first in the world which was worked safely in public streets by electricity. He felt that not only did his own reputation hang upon it, but he had also upon him in some degree the reputation of this thriving town. Not only that, but his scheme was being steadily and critically watched by many important electricians. He wished to thank the company who had given him their support, and if they wished he would give them full details of the working of this scheme, which he might say had been inspected by Messrs. Siemens and others equally capable of judging of its merits, and they all expressed themselves in favourable terms. Councillor Bickerstaffe said they knew he did everything in the interests of the town, and it was principally through his instrumentality that they got their magnificent electric light. That, he believed, was money well spent, as the light was acknowledged to be the best in the kingdom, and was undoubtedly a great source of attraction. This tramway quite eclipsed anything that had yet been attempted in the point of attraction to Blackpool, and would, he believed, be the means of bringing thousands to the town.—Councillor Broadbent said they intended to have the whole of the line complete by Whit Saturday. Carriages had been ordered and would be in Blackpool in a month's time, and he felt confident that the line would be completed by then. The Corporation have entered into an agreement with a company (capital £25,000, which has already been all taken up) which will lease the tramways and pay the Corporation 6½ per cent. per annum on the total outlay, besides keeping the roadway over which the line passes in repair. The company, with which Mr. Smith, is identified, provide the electric apparatus and everything necessary for the proper working of the tramway. Mr. Joseph Copley, of Lincoln, is the contractor under the Corporation, for the laying down of the line.

The New Orleans Exhibition.—The Exhibition buildings and grounds are open till 10 p.m., and the visiting throngs witness such a flood of electric light as has never been seen before. Over 7,000 electric lamps (arc and incandescent) continue the illuminating contract when the sun goes down. The Louisiana Electric Company has been very busy, and but two or three of its thirty-five dynamos remain to be put up. The South Western Brush Company is now running under full head of steam. Five 65-light machines furnish 300 lamps to the Government building and a few to the grounds. The Jenney Company has its groups of ten lamps hung in mid-air, as they appear to be, and are certainly attracting considerable public attention. The plant consists of three each 30 and 15-light machines now running, and two more 30-light to be put in. They furnish 66 lamps to the stock barns, 29 to the waggon building, 8 to some of the walks in the grounds, and 15 to the Grand Rapids Furniture Pavilion. In addition to the above, one Jenney lamp will be placed on the steamboat landing and two in the waterworks building. The Thomson-Houston Company has two 30-light Machines in main building, running in connection with four like dynamos placed in Machinery annexe, from which are wired 75 lamps in Horticultural hall, 23 in saw mill building and 25 in the annexe itself. Besides, they drive four Cleveland motors used by H. Muhr Sons, of Philadelphia, who manufacture souvenir gold rings. They are the only electric motors (the Daft Railway excepted) so far observed in use in the Exhibition. An Edgerton motor, on exhibition, running a sewing machine is also run by this company. The Edison Company has excellently situated space, from the centre of which rises a group of coloured lamps, producing a pleasing effect. Beneath, and under the shadow of its support, hangs a drop light, bringing out in perfect relief the various colours in a piece of patch-work placed below. A case of lamps ranging from one to 100 candle-power, a sample of each of the fifteen sizes of wires used in lighting the Art Gallery; a picture of the "Pilgrim," bearing the legend that she is the largest steamboat in the world, and carries the largest electric light plant afloat (960 lamps); a few sections of underground conduits, a motor and fan, and an armature—this about constitutes the Edison Company's display. The Jenney Company near by displays a

Digitized by Google

large case of Wallace diamond carbons of great variety of sizes, and a miniature star tower upon the top of which are to be placed three Edison incandescent lamps. The Thomson-Houston Company exhibit a number of arc lamps of different mechanical arrangements. A tastfully arranged little office shows the Thomson incandescent lamp to advantage. Among other things, the Roebling Company display hard-drawn copper and also galvanised wire for electrical uses. The American Electrical Works of Providence show a great variety of insulated and lead-covered wires, telephone cords, and aerial cables. Bare wires, both copper and galvanised iron, enter into the very complete exhibit of the Washburn and Moen Company. A thermostat, as simple as it is novel, and an electric bell, with constant ringing attachment, together form a local fire alarm system, and is the electrical contribution of New Orleans to the Exhibition. Electrically speaking, the golden glory of the Music Hall, as seen from its main entrance, and the silvery beauty of Horticultural Hall, viewed from a distance, divide the honours (at night) of the Exhibition, although the electric railway connecting the Government and main buildings, the track being some 1,100 feet in length, commands no small share of public attention. The equipment consists of a Daft dynamo in the main building, a motor, and three cars. The "electric glide," as a trip over this, the first railway of its kind in the south, is called, is now one of the features of the Exhibition."

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.—We have been favoured with the first volume of the *Transactions* of the above-named Institute, which, it will be remembered, was formed in May last. It has now a membership of 300, and bears good promise for the future. We abstract the following portion of a paper, by T. D. Lockwood, upon "Earth Wires; or, the Earth as an Electric Circuit Completer":—"The first instance on record, where the earth or a portion thereof, in the form of water, was used deliberately, as an electrical conductor, to complete an electrical circuit, dates back to July, 1746, when Winkler, of Leipsic, both charged and discharged a battery of three Leyden jars through an insulated wire 37½ yards long, the wire being laid along the bank of the River Pleisse, the waters of which constituted the return part of the circuit. Winkler ascertained by this experiment that the effects of the discharge were not perceptibly different from those observed when a metal discharging rod was used. About the same time Le Monnier, of Paris, made similar experiments, and discharged Leyden jars through the water of a tank in the garden of the Tuileries. We find from Priestley's 'History of Electricity,' that in England, shortly after the above experiments, Dr. William Watson carried out a number of others in the same line, under the auspices of the Royal Society Committee. On the 14th and 18th of July, 1747, the first experiments were made, a wire being carried over the River Thames on Westminster Bridge, the water of the river serving as a return path for the current. On the 24th of the same month, a similar trial was made in a circuit of two miles, at the New River, near London. Two trials were here made; in one of these the electricity successfully traversed a distance of 800ft. overland, and 2,000ft. by water; and in the other the circuit comprised 2,800ft. of land and 8,000ft. of water. In August of the same year it was discovered by Watson that dry ground conducted the subtle force quite as well as water. Again, on August 14th, 1747, at Shooters' Hill, a circuit was experimented with, consisting of two miles of wire and two miles of dry ground. In all of the above trials the electricity was effectually conducted by the earth acting practically as a return circuit. Finally, in 1748 and 1749, these results were verified by Franklin and De Luc. We may note here, by the way, that nearly all of the early proposers or devisers of early electric telegraphs, from Le Sage down to Dyer, had intended to employ the earth as a return. It is also, however, to be remarked that all of the above instances were experiments with high tension electricity; and that thus, if there had been no examples in which voltaic circuits had been completed through the earth, our fathers might have been excused in waiting for Steinheil. But such examples are not wanting, and the conductibility of the earth with respect to chemically-generated electricity was also known for a long time anterior to Steinheil. In February, in 1803, Aldini sent a current from a battery of 80 silver and zinc plates from one side of Calais harbour to the other through a wire supported on masts, the return being through 200ft. of water. He also repeated the same experiment at Paris and Alford, using the Rivers Seine and Marne. Basse, of Hameln, in the same year made a series of experiments by which he fully established the fact that the earth could be used as a part of a voltaic circuit. Erman, of Potsdam, somewhat later, verified these results in the waters of the Hamel; and eight years later (1811) Soemmering and Schilling performed almost identical experiments with a view to establish the feasibility of using the earth as part of any electric circuit. These are the historical circumstances which form a basis for the present system of earth completed circuits; and we may clearly see that as early as the beginning of this century the fact that the substance of the earth in the form either of water or dry ground could be used as part of an electric circuit was well established. In view of these circumstances, it seems very strange that the earth circuit was not used, or even with one exception proposed, for telegraphs, until used by Steinheil in 1838. It is rather difficult to see why a well settled knowledge of the above circumstances which, if acted upon, would at once have halved the number of wires required, was not utilised until so late, even by Schilling and Soemmering, who were two of the earliest telegraphic inventors, and who both, although instrumental in demonstrating the truth by experiment, failed to apply it to their telegraph system. Steinheil's idea to use the earth as a return was in a measure forced upon him, being an observation made of the result of an experiment tried for quite another purpose. Singularly enough, his discovery was foreshadowed in a letter signed 'Corpusculum,' dated December 8th, 1837, and published in the *Mechanic's Magazine*. This letter speaks of the numerous designs for telegraphs, which were then being brought forward, and says that he, too, formed one, and prepared a specification for it, five years ago, including a plan of making one wire only serve for the return circuit for all the rest . . . ; '*but even that*,' he goes on to say, '*might I think be dispensed with, where a good discharging train, as gas or water pipes, at each end of the telegraph could be obtained.*' The *application* of the earth itself, as a return, and a *common* return circuit for telegraph wires, came about in this way:—Professor C. A. Steinheil, of Munich, had in the year 1836-37 constructed a telegraph line, and devised a most ingenious system of operation for the same. In consequence of a suggestion made by Counsellor Gauss, that the two rails of a railway might be used as conductors for the electric telegraph, Professor Steinheil, in 1838, tried the experiment on the railroad between Nurnberg and Fuerth. He was, however, unable to insulate the rails properly, and he found that the electricity passed from one rail to the other through the earth. He then used one rail as the return wire, the direct line being an insulated wire, and found it to work perfectly, for the rail itself acted not only as a return but also as an earth plate. Subsequently he discarded the rail, and substituted earth plates at both ends.

ON THE DESIGN AND CONSTRUCTION OF DYNAMOS.

BY GISBERT KAPP.

(CONTINUED FROM PAGE 347.)

The current flowing through R in Fig. 2 will be the greater the more cells are employed, the higher the electromotive force and the smaller the internal resistance of each cell; and also the smaller the resistance of the loop wire r. Of these conditions that of minimum internal resistance will evidently be most conducive to economy. To obtain it we must employ battery plates of large surface and a stout wire for the loop r; we must also arrange the plates as near together as possible, thus making the battery short. In the magnet (Fig. 3) a maximum of lines will be obtained, the greater the total exciting power (number of cells), the more ampere-turns we get on to the magnet per lineal inch (electromotive force of one cell), the larger the area of core (resistance of one cell), and the heavier the yoke (stout loop wire r). It will also be advantageous to make the magnets short, which corresponds to the shortening of the battery, by arranging the plates as near each other as possible. In this respect, however, there is a limit. In the first place a certain length of core is necessary in order to get the required amount of copper wire on; and, in the second place the leak of lines would be unduly increased by making the magnets too short. In the battery the path of the current is well defined; it has to circulate round this path, and no part of the current can take a short cut across from one row of cells to the other unless a conductor is provided. With our magnets the case is different. The lines can take a short cut from one arm to the other, since air, or any other medium, acts to a certain extent as a conductor for magnetic lines of force. To maintain the analogy with the battery we

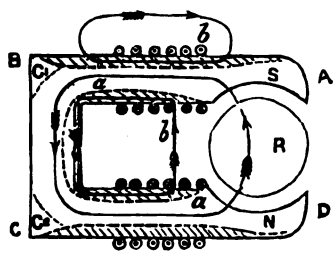

FIG. 4.

must suppose the same to be submerged in water or other imperfectly conducting medium, if such a thing were possible without spoiling the cells. For argument's sake, suppose it to possible, and see what happens. An intricate system of currents will flow in all possible directions, but always from places of higher to places of lower potential. This leak of current will be the more serious the smaller the distance between points of greatly varying potentials and the larger the surfaces of leak. The shorter the battery and the larger the plates the more current will be wasted laterally, and consequently there exists a limit beyond which a reduction of internal resistance would do more harm than good. The current leaking out laterally monopolises a certain portion of the surface of the plates, leaving the remainder for the passage of the current, which does useful work in R, and so it comes that the greater the leak the less useful current can be obtained.

We may regard our electro-magnet as such a battery submerged in an imperfectly conducting liquid, in this case air. Let in Fig. 4 A B C D be the magnet with armature R interposed between the poles S N and traversed by lines, one of which is shown at $a\,a$. These we may call the useful lines. They are due to the internal wires (marked with a cross) in which the current flows towards the observer. Besides these useful lines the current also produces useless lines, $b\,b$, some of which are due to the internal wires, and run across from one arm to the other; and others, which are due to the external wires and run longitudinally from end to end on each arm of the horseshoe, as shown. Evidently, these useless lines must be accommodated somehow within the core of the magnet, and they monopolise part of the cross sectional area. To make this plain in the sketch, the space which we imagine to be required for these lines $b\,b$ has been shaded. In this way the space at the disposal of the useful lines is somewhat reduced, and the general effect is the same as if through the reduction of cross sectional area the magnetic resistance had been increased. How much increased depends on the arrangement of the magnet. The core should not be too short, and the two arms should not be too near each other; there should also not be any projecting points which would shorten the path of the lines b through the air. At one time it was thought that huge pole pieces, as shown in Fig. 5, would greatly improve the machine. At the same time the yoke was extended so as to come beyond the exciting coils, and thus an easy and pleasant path was created for the useless lines to the detriment of the useful ones. For the rest, all sharp corners should be avoided, and the form of magnets shown in Fig. 4, although very superior to Fig. 5, could still be improved by rounding off the corners C_1 and C_2.

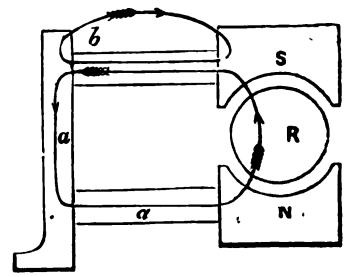

FIG. 5.

It might be asked how the loss of conducting power of the magnet core consequent upon the leak could be calculated? The author is bound to confess that he does not know how to do it with any pretence to accuracy, and has never attempted it, since in practice, and especially with modern dynamos, the number of lines wasted by leakage is very small as compared to the number of useful lines. However, a formula will be given below for finding the magnetic resistance of the air space between the polar surface and external surface of armature-core. Supposing the formula to be applicable to cases where the surfaces are not opposite and near each other, then the magnetic resistance of the air surrounding the magnets could, with a good deal of trouble, be calculated approximately, and from it the number of leaking lines could be estimated.

Referring once more to Fig. 4, it will be seen that the useful lines $a\,a$ are entirely due to the inner wires, and that the outer wires not only contribute nothing to these lines, but, by creating a leak, reduce the available cross section of the magnet core, and thus are, to a slight degree, detrimental to

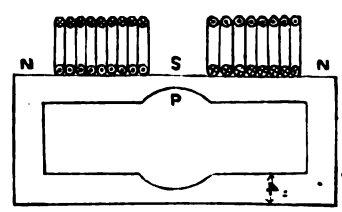

FIG. 6.

the working of the machine. By no possibility can a line of force belonging to one of the external wires go through the armature. This follows from the fundamental conception that each line must be a closed curve surrounding its wire, and it would hardly require further proof. But to exclude all possibility of error the author has made the following experiment, to show that the external layers on a horseshoe magnet contribute nothing to the strength of the field, although they make the external surfaces of the pole pieces strongly magnetic. The wrought-iron carcass of a dynamo was used for the experiment. It consisted of a double horseshoe, composed of straight slabs 4in. by 15in. in cross section, having polar cavities bored out in the middle, as shown in Fig. 6. Flat coils were placed on top, and so connected that the current flowed from the observer in those wires, which were close to the iron on the left, and towards the observer in the wires to the right.

Digitized by Google

The current in the top layer of each coil flows, of course, in an opposite direction, but as these are comparatively far from the iron, their influence on the core is much less and, as was to be expected, the differential effect of the near and far layers was evidenced by strong magnetism in the points N S and N. But in the polar cavity at P not a trace of magnetism could be found. The question now presents itself, whether it be not possible to construct a dynamo without any wire on the outside of the horseshoe. The advantage of such a machine would not only be a saving of wire but also a saving of iron, because the absence of external lines would admit of using a core of smaller cross-sectional area. This problem is, however, not an easy one, and for two-pole machines it has, as far as the author knows, only been solved in one single case. The difficulty lies in this, that the current has to be led in the same direction on both arms of the horseshoe, and it is only in the Hochhausen machine (Fig. 7) that this condition has been fulfilled, at least partially, by the device of exciting only one of the arms of each horseshoe. The machine can be considered to consist of four horseshoe magnets N A B C, N A H G, S E D C, and S E F G. Only the arms N A and S E are directly excited, whilst the other arms, being farther removed from the

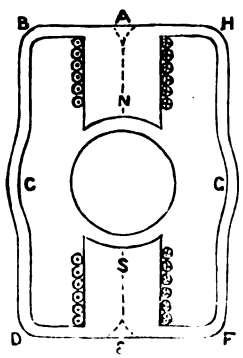

Fig. 7.

coils, are themselves only slightly excited, but serve the purpose of conducting the lines from E to A, in the same way as the yoke in an ordinary horseshoe. From what was said above, it will be seen that this machine could be improved by making these conducting pieces much heavier, than shown in the sketch.

In four-pole machines the problem of avoiding waste wire is solved without difficulty. One method (as far as the author knows not yet tried in practice) is shown in Fig. 8. Only two coils, *a a* and *b b*, are used, filling completely the shaded space shown in the sketch. The direction of the current in each space is indicated by the little circle with a dot or a cross, and it will be seen that four poles, N S N S are thus produced.

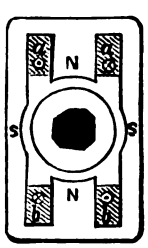

Fig. 8.

The only waste wire, and that only partially wasted, will be at the ends in front and at the back of the machine. From a practical point of view, this arrangement of field has also the advantage that the whole of the carcass could be cast in one solid piece, the central space required for the armature being large enough to allow the introduction of the coils. Against this it must, however, be urged that the days of cast iron as a material for magnet cores are nearly over, and therefore this advantage of simplicity is hardly worth considering. The arrangement seems, nevertheless, worth a trial on account of its cheapness and compact form.

Another method of avoiding waste wire has been adopted in machines made by Gramme, Varley, and others, and is shown in Fig. 9. The advantage of this arrangement over Fig. 8 is that, in consequence of a perfectly symmetrical dispositions the same number of lines emanate from each pole, and thus entire freedom from sparking at the brushes is insured, a point which in the previous arrangement is somewhat doubtful.

Before leaving the subject of waste wire it will be necessary to consider whether the wire joining the inner and outer layers of each coil contribute anything to the useful lines. If we imagine for a moment the field-magnet and armature to be of wood or other non-magnetic substance, the lines round this part of the coil would be curves lying in planes parallel to the axis of the armature, and either missing the latter altogether, or, if they cut it, entering and leaving on the same side, and therefore not contributing anything to the electromotive force. But since the core, pole-piece, and armature are made of iron, these lines will be no longer plane curves, but as shown at the beginning of these articles, curves of three dimensions. Then we found that the curves can be deflected up to an angle of 90°, although the more their deflection approaches this limit the weaker do they become. If we now arrange the carcass of our field magnet in such a way that the length of pole piece and armature measured parallel to the axis is somewhat greater than the width of the magnet core measured in the same direction, the lines belonging to the wire at either end can still reach and go across the armature, their distortion being less than 90°. The wire joining the inner and outer layers on each magnet core is therefore not totally wasted; it does contribute to some extent to the production of useful lines, although not so effectively as the inner wire.

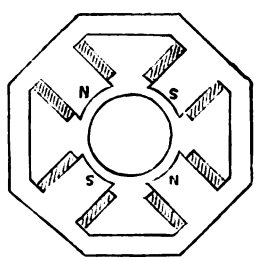

Fig. 9.

In disc machines, where the magnet cores are arranged parallel to the axis, there is also some waste wire, as can easily be seen by drawing a front view of the disc with the magnet cores in cross section and excluding all the lines as impossible, which would have to be distorted through an angle greater than 90°. It will then be seen that with circular cores one-half the wire is wasted in two-pole machines, and one-quarter the wire is wasted in four-pole machines.

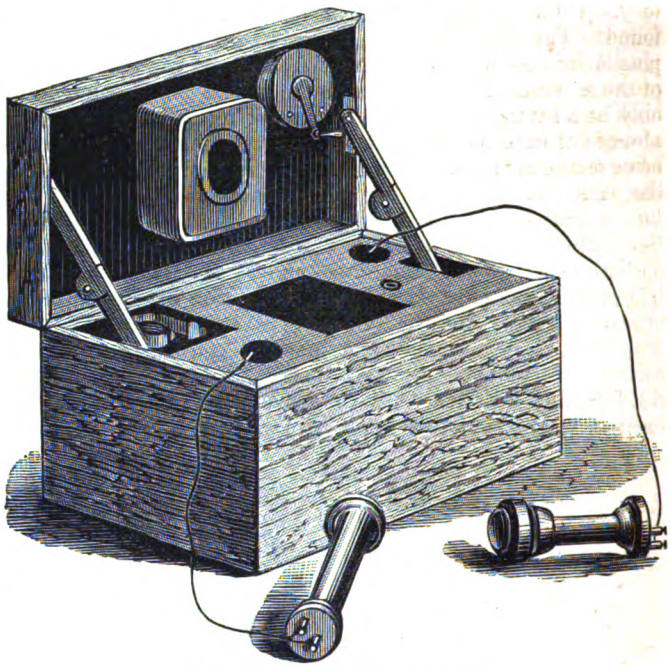
(TO BE CONTINUED.)

THE BIRTHPLACE OF THE TELEPHONE IN ENGLAND.

Beyond the limits of a circle of scientific men, enthusiasts, and editors of newspapers, who know, or who are supposed to know, everything, the telephone, for an instrument of such wide utility, is but little understood. The reason for this is perhaps not hard to find. In all probability no other appliance, mechanical or electrical, has been the subject of so much litigation, is more thoroughly hidden, more jealously guarded by monopolists, or under more restrictions than the apparatus commonly included under the heading of "the telephone." Since it was given to the world in its rudimentary form the information afforded to the public with regard to it has been almost purely theoretical in its character. At the present time the monopoly enjoyed by the telephone companies has placed a prohibitive duty upon economical experiment. The telephones and microphones of to-day are inaccessible to those who have the command of but moderate means. They cannot be purchased in England, nor are they procurable for purposes of experiment, except upon the payment of a heavy royalty; or of a subscription which merely entitles the subscriber to have the limited use of one set of apparatus.

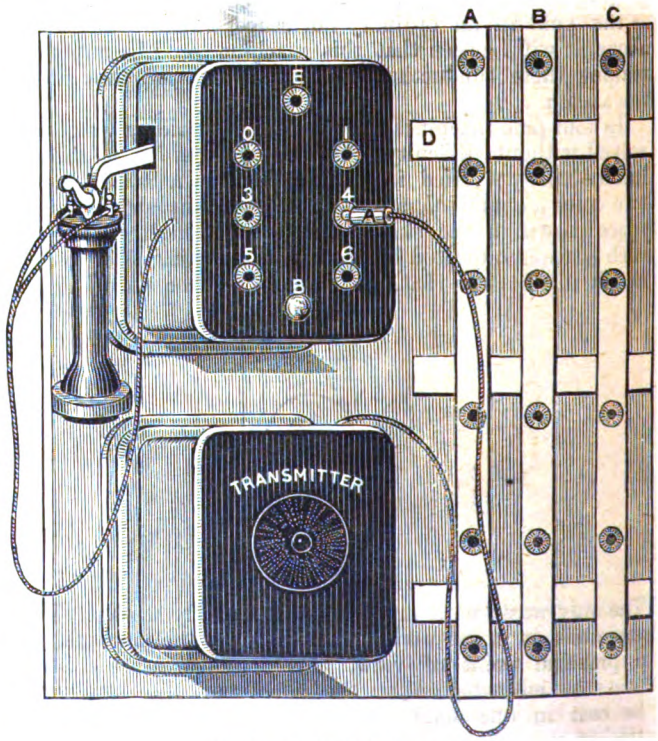
Digitized by Google

Under such circumstances it is not surprising that so little real knowledge of the actual constitution of the telephone exists. The restrictions are no doubt necessary. Invention should be protected and encouraged. We can only lament that as a consequence a tax is indirectly imposed upon anything like extensive research. During the past week we were enabled by the courtesy of Mr. Charles Curtoys, the secretary of the Consolidated Telephone Construction and Maintenance Company, to pay a visit to what may not improperly be called the birthplace of the telephone in England, in that at the company's works in the Farringdon-road the telephone industry is more largely represented than in any other manufactory in the United Kingdom. Thanks also to Mr. Mason, the general manager, who was our cicerone on the occasion, and who made our visit a very interesting and a very instructive one, we had the opportunity of inspecting some really first-class machinery, and of entering into all the details of telephone construction. On the ground floor of the premises is the machine room, in which, in addition to a number of lathes, drill presses, &c., and a whole host of tools of every sort, size, and description, we noticed, as exhibiting perfection both in design and workmanship, two screw-making machines, capable of manufacturing from 1,000 to 1,500 screws or terminals per diem; one making 4,000 to 5,000 small screws per diem; an automatic punch press to make 90 blanks up to 6in. in diameter per minute; a punch press making 150 blanks per minute; an automatic tapping machine tapping from 30 to 50 holes per minute; and a universal index milling and gear cutting machine which seemed to be capable of making almost anything, from a toothpick to the most complicated forms of spiral gear. There, also, were horseshoe magnets for the magneto bells undergoing saturation at the rate of about two per minute, the current being supplied by an Edison Z dynamo, driven by a 60 horse-power Gwynne horizontal engine, which also serves six Thornton arc lights on the lower floor, and 220 twelve candle-power Edison incandescent lamps throughout the building. Another feature of interest was the process of depositing brass upon iron by electricity. We understand that the method is not very generally known. We can, however, testify to the excellence of the imitation, and the neat appearance of the screws and other constituent parts of the apparatus which were so treated. On the first floor we were shown the fitting room, where the thousand or more parts of the telephone, magneto-bell, and transmitter, were being pieced together by boys. This is but a simple operation, in that all the component parts are so accurately made by machinery, are so mathematically exact in their proportions, and therefore fit so easily in their respective places, that their combination is a mechanical operation calling for the display of no other quality than that of attention. At a centre table was a member of the fair sex winding the coils of a magneto bell, an instrument capable of ringing through 30,000 ohms resistance; at others were skilled workmen soldering the platinum contacts to delicate springs, &c., while on every side were to be seen, in various stages of completion, large numbers of the Gower-Bell and almost every other form of telephonic apparatus which has successfully withstood the test of our time. One very ingenious, and, we think, very useful, contrivance, to which we especially directed our attention, was the telephone apparatus for the use of divers. Without doubt, in diving operations the telephone forms a very important addition to the equipment of a diver. It gives him a means to communicate with those on the surface of the water, and by this means he is able to make known his wants, and to receive more prompt assistance in the case of danger. The apparatus consists of a cap, to which is fitted two telephone receivers; this cap is fitted to the diver's head, and the receivers are arranged to cover the ears. The cap is secured by means of a strap and buckle, and the diver's helmet is then placed over the head, but before being secured, a connection piece, which is attached to a flexible cord, is placed in a socket at the side of the cap; this connecting piece and cord is in communication with a magneto-transmitter fitted into the side of the helmet. The telephone for use on the surface is contained in a strong wood box, and consists of a carbon transmitter, a switch (which is used to connect the battery to the transmitter), and two telephone receivers, one of these being placed to each ear. A cable with an insulated electrical conductor inside is used to connect the instrument used by the diver and the instruments on the surface.



Telephone Apparatus for Divers.

Amongst the other apparatus which we had the pleasure of inspecting was the Domestic telephone, and a Public telephone for police, fire alarm, and other purposes. The former provides for a means of telephonic communication between rooms or departments of public or private houses, having at the same time an independent connection by private wire with a central

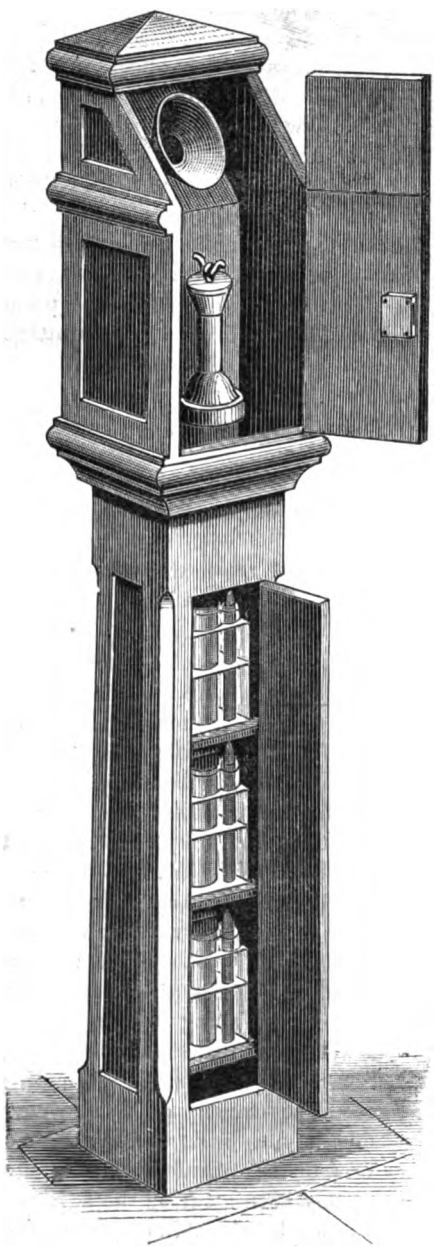


The Domestic Telephone.

exchange system. The arrangement of wire and the mode of operation are very simple. In a house of eight rooms, for example, an instrument is placed in each room, and wires, either separate or in a cable, are then run from No. 1 room to No. 8 room, each of the wires being numbered; these wires

Digitized by Google

are then connected to their respective numbers on the instruments—that is, No. 1 connected to the zero of No. 1 instrument, and to the No. 1 socket of all the other instruments. The battery and earth wires are included in the system and connected to all the instruments, thereby requiring one battery only for the entire system. The mode of operation is as follows: Say No. 1 wants to speak to No. 4, he will insert the plug A into socket 4, the act of inserting the plug with slight pressure rings No. 4 bell; then take the telephone from its hook and listen. No. 4 will then have inserted his plug in the zero of his instrument to ask what is wanted. Communication being thus established, one can ring off by again slightly pressing the plug. It is not necessary to remove the plug until a call



The Public Telephone.

is received or it is wished to call; in fact, it makes no difference whether the plug is in or out of one of the sockets; or if the telephone is off or on the hook, the call can always be received; but when called it is necessary to insert the plug into zero and speak.

The socket E is intended to be connected by private wire to a central exchange system, and is so arranged that, by pressing the button B, the exchange may be called. A bell is also provided, so that the exchange may call the subscriber. To arrange this the plug A must be inserted into the socket E, and B be pressed; the telephone is then taken off its hook, and applied to the ear. When through, one can ring off by again pressing B. One great advantage of this is, supposing that there is but one private exchange wire included in a system of domestic apparatus, and that No. 4 should want to speak to the exchange, he could do this by calling up No. 1, and asking him to connect his wire through. No 1 would then insert two plugs, one in socket 4, the other in socket E, and ring No. 4, and the exchange then would be in circuit, and No. 1 would still be able to communicate to all others included in the domestic system. To extend the system it is only necessary to provide switches for the additional number of wires run, and to the original strips having sockets and battery connections, as A, B, C and D. The switch itself may be included within A transmitter, and with or without the zero and E socket. Strips similar in principle to A, B, C, carrying all of the wires.

The Public telephone, as shown by our illustration, is fixed on an ordinary street post, duly protected, and is placed in communication with any fire engine station, police station, or any other place required for communication, such as docks, &c. By means of an annunciator, placed in any selected spot, it is at once seen from whence the communication is coming, and by using the telephone, which can be placed under lock and key, for the use of subscribers, any necessary communication can be made. Such a telephone, if carried into extensive use, would prove of great service to the public in cases of emergency; keys might, for instance, be granted to anyone subscribing a moderate sum, so that a ready means of communication with the police, fire stations, or a central office might at all times be within reach. We should like to see them erected in all the principal thoroughfares of the metropolis, and the sooner the better, for everybody concerned.

Having thus reflected, we, under the friendly guidance of the energetic manager, ascended a labyrinth of staircases, and were at length confronted by a number of young people who were winding coils for the Gower-Bell and other telephones, and very expeditiously and very neatly they got through their task. In a small room close at hand a lad was testing the finished coils for resistance by means of a Wheatstone bridge and a tangent galvanometer. The limit of error allowed was, we were informed, about one per cent. on the rough test merely. In conclusion, we have to congratulate Mr. Curtoys upon the evidences of prosperity which were everywhere to be seen; and we advise those who have an hour or two to spare, which they would employ to good advantage, to pay a visit to the birthplace of the telephone.

THE INTERNATIONAL INVENTIONS EXHIBITION.

There are but few persons who went to the Fisheries and Health Exhibitions who will not remember the excellent manner in which those buildings were electrically lighted. The Executive Council have decided to light up the whole of the buildings of the Inventions Exhibition by this most excellent and best of all artificial lights, and the contract for supplying the whole of the motive power for driving the electric light machinery has been placed in the hands of Messrs. Davey, Paxman, and Co., engineers, of Colchester, who, it will be remembered, so successfully supplied the power at the two previous exhibitions. The plant (ten steam boilers and five powerful steam engines), as supplied by Messrs. Davey, Paxman, and Co. last year, is retained, and besides this eight additional large locomotive boilers will be provided by the same firm. These new boilers will all be made of best quality steel, and have all the most modern improvements. Each boiler will contain 610 square feet of heating surface, and these eight boilers, with easy firing, can evaporate 36,600lb. of water into steam per hour. The total number of boilers will be 18, so that 110,000lb. of water can be made into steam of 100lb. pressure per square inch per hour. It will thus be seen that an enormous amount of power is provided for the Executive Council by this firm, who we congratulate upon being again elected for this important undertaking.

PRIMERS OF ELECTRICITY.—These Primers (by Prof. Houston and others), which had a large sale at the recent Philadelphia Exhibition, can now be obtained at the office of *The Electrician*, price 1s. the set of twenty-seven.

CONDENSERS.

We invite those of our readers who are Electricians and who have Condensers in their charge to kindly furnish us with information as to the actual capacity of such Condensers as against the nominal value; together with a note of the temperature readings with both wet and dry bulbs; and any other data which may be of interest.

A PROPOSED NEW ELECTRIC LIGHTING ACT.

The Committee appointed by the Electric Lighting Corporations to consider the possibilities of amending the existing Act have promptly accepted the challenge to let the Board of Trade know exactly what the Corporations want; and, as we predicted at the time, they have seen no other way of usefully amending the obnoxious Act than by demanding the absolute repeal of the 27th clause. A thorough examination of the whole subject both for its immediate and future possibilities has shown the Committee, in fact, that the only way in which the promotion of Electric Lighting can be made practicable as a business concern is by placing it precisely on the same footing as that on which legislation of recent years has placed the gas light companies. The Committee have drawn up a Bill on this basis, and a deputation to back it up with arguments and facts is to seek a fresh interview with the President of the Board of Trade.

We print elsewhere the "Reasons" put forward by the Committee in support of the various provisions of the Bill as drafted by them. They will be seen to be eminently sound and reasonable. To our thinking they are unanswerable as touching the utterly objectionable character of the existing Act, and the necessity for its repeal. We have from the very first condemned that Act, and we do so still; and in so far as the present movement tends to get rid of it we are heartily in accord with the Committee. We are not quite sure that we are anxious to see that Act substituted by another, however harmless its provisions may be. We cannot entirely divest ourselves of apprehensions lest the mere fact of legislative sanction in a new form might have just the same effect that the first parliamentary essay of that kind had on public confidence—that is to say, it might give an unnatural impulse to company promoting, and an over-confident supply of capital on the part of the public, so that in a very short time there would be another series of collapses and a further shock to public confidence which might prove even more disastrous than the last. We want to see the electric light progressing by natural growth; we do not think it wants parliamentary help, nor that it would be any the worse for having no such help. By obtaining parliamentary recognition it acquires an artificial status which may be seductive to the public, and which may tempt the undertakers into enterprises beyond their present powers. A speculative era might set in which, although pecuniarily profitable to those immediately alive to its advantages, might do no permanent service, but rather the reverse, to the cause of Electric Lighting.

At the same time we are strongly in accord with the Committee in desiring the complete abrogation of the 27th clause—the clause which empowers the local authorities to buy up the undertaking at the end of twenty-one years. The newspapers have been too busy with urgent foreign affairs of late to bestow any attention on the proposed new Bill. But an evening contemporary which is always ready with a decisive opinion upon anything and everything on the shortest notice has in one short paragraph disposed of the Committee's labours. If, says the *Pall Mall Gazette*, the Committee imagines it is going to be allowed to set up a lot of monopolies without the option of local purchase, *it is greatly mistaken.* Now, if a monopoly were demanded without any obligations attached to it, the case would deserve to be dismissed in this off-hand fashion. But the would-be monopolists voluntarily assume all the obligations and responsibilities which pertain to monopolies in general and to those attached to gas-lighting monopolies in particular. Therefore, what our contemporary really means is that there shall be no more monopolists except such as can be extinguished by parochial vestries the moment the monopolies have become worth extinguishing by the process of expropriation from the hands of the undertakers to the hands of the parish. No reason is assigned for this astounding proposition, which has no precedent except the tramway companies, and this a very bad one, besides being one that has no resemblance to the industry now under consideration. The newspaper we are quoting has lately been assuring the British public night after night that the whole subject in dispute on the Afghanistan frontier is a piece of waste grass land and a wooden sentry-box. Similarly, the matter in dispute with the electric light promoters is one solely of monopoly. These positive misstatements, on the one hand, and suppression of facts on the other, are deliberately designed for misleading public opinion; and we connect them together in this relation to show the worthless character of criticism from such a quarter, able and influential as that quarter undoubtedly is.

The *Pall Mall*, we suspect, merely utters the shibboleth of a political party when it declares against the monopoly of private corporations. We want to know its objections. If it favours State socialism, the absorption of all public works by the State or the parish, let it say so. We, for our part, have no objec-

Digitized by Google

tion. But we do strongly object to do all the dirty work for the State or the parish, and then to be sent about our business with empty pockets. We object to being treated as *primâ facie* public enemies, allowed to live only on sufferance, and to be gobbled up directly we are fat enough to be eaten. We decline to do all the experimental and hazardous preliminary work for the public, with nothing sure at the end of it but confiscation if we happen to be successful. Let the State take up the initial stages, and we will help it in every way we can to make the business succeed; but we flatly decline to run all the risks of a monopoly without enjoying any of its advantages.

The Committee have taken their stand on these sound principles and do not intend to depart from them. We do not think the Board of Trade will yield. Political fanaticism in that department is too thick skinned to be penetrable by sound argument or precepts of common honesty. The business of Electric Lighting is probably fated for some years to come to work on its own bottom in departments of activity where the State can neither harass nor confiscate it. On the whole we are not inclined to grieve on this account; on public grounds we certainly do lament the circumstance that a great public benefit has been hindered by what is nothing less than a mere political fad which happens to be in the ascendant just now. But in the long run perhaps the electric lighting promoters will be the gainers; and even now they have a wide field of operations open to them which, if diligently cultivated, will yield a profitable harvest in defiance of the existing Act of Parliament, and without the artificial help even of any new Act that the present Committee might approve of.

CORRESPONDENCE.

THF WIMSHURST ELECTRICAL INFLUENCE MACHINE, ELECTRICAL UNITS, &c.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is indeed a welcome, but infrequent, number of your journal that is distinguished by two letters so pregnant with the esoteric philosophy of electricity as the current impression.

It has been conjectured by those who have read between the lines of the latter pages of the history of dynamic electricity that the pioneers of dynamo design have been groping round the truth that centifrugal force is the radical cause of the electric current. The mere fact that in the older armatures there were many layers of wire, and that by degrees the depth has been decreased until one layer is found to be more than sufficient, is proof enough that it is not the wire, but the tangential inertia that polarises the commutator. It has been well known that boreal aurora is due to the axepetal tendency of equatorial E.M.F.

He was a bold man who first attempted to produce electric light at a distance by incandescence caused by the transmission of heat along the wire, for, as your correspondent writes, ordinary heat will not travel along a wire; but now, by producing disruptive deliquescence of the ether at the periphery of the rapidly-rotating armature, the decrystallising influence creates such intense cold that the inrush of radiant energy produces incandescence by the mere absence of cold at the remote end of the wire. The simple reason why this was not discovered before is that the ether is a perfect non-conductor of cold, which therefore could not be perceived. Hence the reason for applying sulphur to hot bearings.

Intimately connected with this is the relation of force and mass. For since force $= \frac{ML}{T^2}$ mass = force multiplied by the reciprocal of acceleration. Therefore, with the acceleration of the armature the E.M.F. varies inversely as the mass of copper on it. There is some substantial probability in this hypothesis, as it is supported by more than two experimenters' results. Should, however, the shellac become sticky, and therefore actually increase in weight under the strain of centrifugal force, the decrease of dielectric strength will tend to induce, or rather influence, a Peltier effect which may lead to sparking. This can be readily obviated by making the lead of the brushes a harmonic function of the mean radius of gyration of the switch handle.—Yours, &c. T.

A NEW INDUCTION TELEGRAPH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to the account published in your issue of 7th inst., headed "A New Induction Telegraph," may I point out that this invention forms no exception to the old proverb relating to the majority of things under our sun.

In the absence of earlier dates, however, I may state that this system of communicating with moving trains by means of electrical induction, almost exactly as described, was invented by me as far back as 1881, and actually tried electrically far enough to prove its complete feasibility.

My object was chiefly to provide an efficient means of fog-signalling, by enabling the signalman to communicate directly with the drivers or guards of moving trains.

I proposed to run a wire along the permanent way, parallel with the rails, and to wind a coil of wire round the engine or carriage to be communicated with in such way as to get as long a length of wire parallel to, and as near to, the line-wire as possible, so as to be well exposed to the inductive action thereof, exactly as is now done. I then proposed to place in the signal-boxes a battery, signalling key, and rapid "make and break," or "buzzer," as your account calls it, and to thereby signal to the train, using a telephone on local circuit with the car-coil as a receiver. By using an ordinary carbon transmitter on direct circuit with the line wire, I also arranged and found it quite practicable to speak verbally to the train, so as to be heard distinctly in the telephone or telephones in the "car-coil" circuit.

This design was embodied in a paper which, in the year 1881, I laid before the managing director of the United Telephone Company. Want of time and opportunity alone has prevented it being put into practice. It was also tried practically at that time, using wire coils, properly proportioned in length, resistance, and distance apart to the conditions that would be obtained in practice. The trial was certainly not made on an actual moving engine, but the fact of the coils remaining stationary instead of moving could, of course, make no possible difference, since the speed of the fastest engine is practically *nil* compared to the rate at which the contiguous particles of a line wire are affected by an electric current, *i.e.*, the "speed" of the current. It has also been since simplified and arranged to produce both visible and audible signals on the engine or car by induction from a No. 8 iron line wire across a space of six inches, and using a current of only $\frac{1}{4}$ ampere, that is such as can easily be produced by the ordinary Daniell batteries used in railway work. The signals are also undisturbed by great vibration.

The possibility of communicating with moving trains by means of electrical induction was also suggested by Mr. Willoughby Smith in a paper read before the Society of Telegraph engineers last year, so that the principle can certainly not now be called new.—Yours, &c.,

A. C. BROWN.

11, Old Broad-street, London,
March 17, 1885.

THE SKRIVANOV BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Would you kindly inform me through your valuable columns:—

1st. In what proportions chloride of silver and the zinc plates should be used to produce the effect described in your issue of this day? 2nd. Where the battery could be obtained and the cost? 3rd. If it could be made in a more convenient

Digitized by Google

form to fit the back? 4th. How long one charge will last, and the cost?

By so doing you would greatly oblige, yours, &c.,

A CONSTANT READER.

Newcastle-on-Tyne, March 14, 1885.

[We insert this letter although contrary to our usual course, the writer not having sent his name. A somewhat similar letter, also without name, has reached us from Edinburgh.—ED. *E.*]

THE COX-WALKER LAMPHOLDERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you kindly allow me space in your journal to hank Mr. Sydney F. Walker for his flattering referencc to the bove and our general work in your last week's issue?

His experience, too, as regards the fusing of the old "loops nd hooks" is very valuable evidence of the need of my new plan of making contact with the hooks, which will entirely prevent this fusing, so far as contact can do it; whereas, so long as two round wires at right angles are used for this purpose, the actual point of contact must be almost a mathematical one, and great resistance, loss of energy, and possible sparking the result.—Yours, &c., E. COX-WALKER.

March 16, 1885.

AN EARLY ELECTRO-MAGNETIC LOCOMOTIVE.

In the interesting account of electro-motors contained in a letter of Professor Moses G. Farmer to C. W. Field, and published in the *Scientific American* Supplement of January 17, there is a description of a small electro-magnetic locomotive, constructed in 1851 by Thomas Hall, of Boston, and which operated by an electric current conveyed by the rails, probably the first instance of an electro-locomotor deriving its

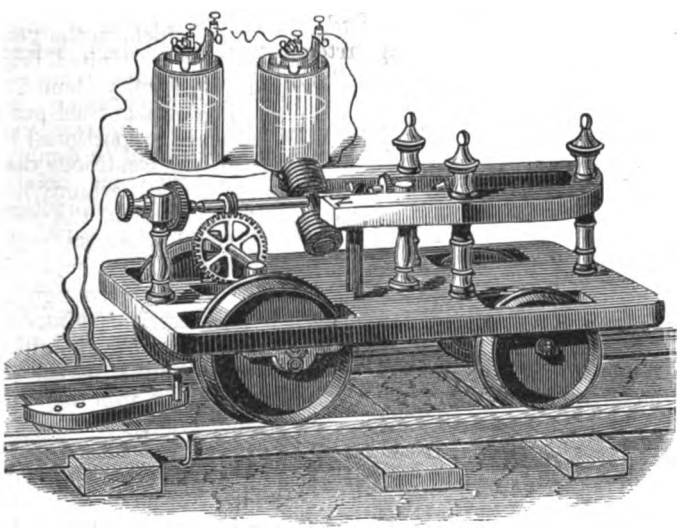

FIG. 1

actuating current from a stationary electric generator. This engine, with a part of its track, is represented in the accompanying cuts; it is owned by E. Dwight Kendall, consulting chemist, of Brooklyn, who purchased it, soon after it was made, of Daniel Davis, Mr. Hall's former employer. Professor Kendall occasionally used it in his lectures to illustrate electro-magnetic force.

The current of a battery or small dynamo electric machine is conveyed to the rails, the connections being made as shown in Fig. 1. The rear axle M (Fig. 2, being an inverted plan view of the locomotive) consists of a central wooden portion which is slotted to receive a standard projecting from a brass plate screwed to the bottom of the car. A bar connects the pivot pin with the shaft carrying the wheel K, which takes up the current from the rail; the other wheel, being insulated by the wooden portion, has no effect upon the current using the rail it runs upon. Both these wheels are loosely mounted. The current is led from the wheel K through pivot, brass standard, and wire to brass plate G. The front wheels are rigidly mounted upon an axle, at the centre of which is secured a gear wheel. One wheel is insulated from the axle by means of an ivory sleeve, L. The current passes from the rail through the wheel J, through the axle bearing and wire to a standard provided with a collar formed with an arm to which the lever A is fastened. This lever is insulated from the collar arm by a block of wood. Soldered to the rear end of the lever is a wire, one section, D, being always in contact with the plate G, and the other section, B, being turned and passed under the lever so as to rest in contact with plate E, which is one of a pair on the bottom of the car at each side of the standard. A wire, C, from the collar is in contact with plate F. By means of the lever, the pieces B and C can be brought in contact with either of the plates E and F. From the free end of the lever a short bar projects downward, so as to be struck and moved to one side or the other by the blocks H I, which are placed, one at each end of the track, at such an inclination as to move the lever sufficiently to change the plates with which the points B and C come in contact.

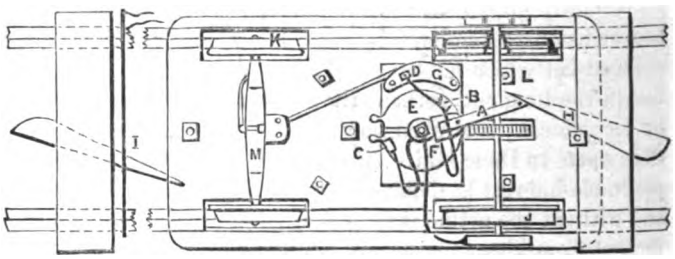

FIG. 2.

Mounted longitudinally upon the top of the platform is a shaft carrying an electro-magnet, revolving between the poles of a horseshoe magnet and a worm, which meshes with a gear wheel engaging with the wheel on a forward axle. The wires from the magnet lead to two semi-cylindrical pieces at the rear end of the shaft, against which press two springs connected respectively with the plates E and F. The path the current travels, when the lever is in either of its two positions, to revolve the magnet first in one direction, then in the other, will be understood from what we have said and from the engravings. With the current from two or three Grove or chromic acid cells the little locomotive exhibits great earnestness of purpose, and runs with respectable speed.

A RULE FOR RECOLLECTING THE DIRECTION IN WHICH A CURRENT IS INDUCED IN A CONDUCTOR WHEN MOVED IN A MAGNETIC FIELD.

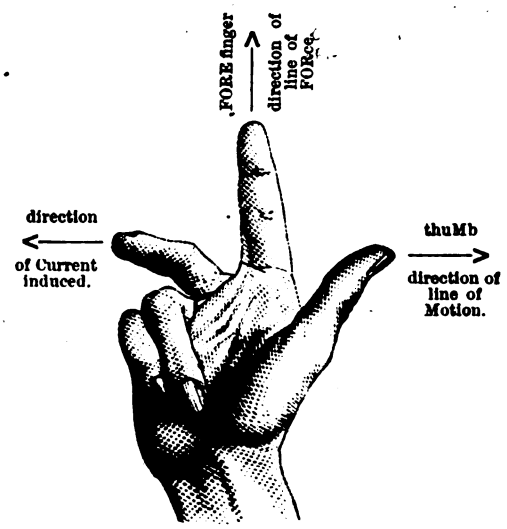
BY DR. J. A. FLEMING.

Writers on electricity have given various rules for recollecting the direction of the current induced in a conductor when moved so as to cut lines of magnetic force and alter the amount of magnetic induction passing through the circuit. These rules depend generally on some association with the position and motion in swimming, or upon the direction of the cardinal points and the motion of the sun, earth, &c. Apart from the difficulty of recollecting the rules themselves, it requires an effort of imagination to apply them to the case of an armature, bar or wire, disc or loop, and as a means of economising time and brain labour I have found the following rule very useful for many years. Having recently given it to a class of engineering students, and finding it assist in thinking out various cases of induction, it is described here for the benefit of others.

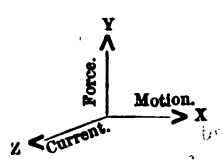
If any circuit is being moved in a magnetic field, and it is required to know the direction in which electricity is being urged in any portion of the circuit which is cutting lines of force, proceed as follows:—Hold the first and middle fingers and thumb

Digitized by Google

of the right hand in a position as nearly as possible at right angles to each other, so as to represent three co-ordinate axes in space. Make the following associations :—Let the direction of the fore finger represent the direction of the lines of Force (FORe and FORce). Let the direction of the thumb represent the direction at right angles to the direction of the field in which the element of the circuit is moving (thuMb and Motion), then the direction of the *middle finger* represents the direction of the induced current (Induced and mIddle). When once these links have been made, the directions of these three vectors will always remain related in the mind, and all that has to be done is to hold the right hand, with the fingers and thumb fixed in the position shown in the figure, and twist the

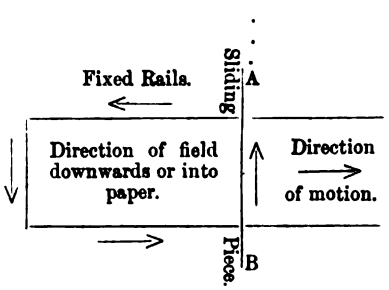


Right Hand.



Three axes at right angles, indicating respectively direction of line of Magnetic Force, Y, line of Motion of Conductor, X, and direction of current induced, Z.

hand about until the forefinger coincides with the direction of the field (which can always be ascertained by a pocket compass), and the thumb points in the direction of motion of the piece of the conductor considered (it will, of course, be in a tangential direction when considering a wire in a revolving armature), then, without any thought at all or references, either astronomical or natatory, the middle finger gives the direction of the actual or potential flow. A few simple cases considered, such as Faraday's copper disc between the poles of a horseshoe magnet, or the usual illustration of a pair of rails and sliding piece, will serve to fix the rule.



Take the case of a sliding piece slipping parallel to itself on a pair of conducting rails. Let the direction of the field be perpendicular to the plane of the paper, and let the lines of force run *from* the reader. Then applying the rule, it is instantaneously seen that the direction of the current is in the direction of the arrow marked along parallel to the sliding piece, and that the current circulates round counter-clockwise in the closed part of the circuit, when the sliding piece A B moves to the right. The rule is easily applied to all parts of the armature of dynamo machines. Now, let it be observed that in finding the direction of the current induced we use the right hand, but if we use the *left* hand instead, it provides a rule for determining the direction of motion of a conductor under the influence of a field when traversed by a current. The same associations are made for the three directions, but as by Lenz's law motion is opposite for same current or current opposite for the same motion, it is seen that the passage of a current creates a motion in the opposite direction to that motion which would have induced that current, because the left hand is the perverted image of the right hand. Hence we associate also *right* hand for *dynamos*, *left* hand for *motors*, directions of force, current, motion always in both cases indicated by the direction in which the fore finger, middle finger, and thumb respectively point.

UNDERGROUND WIRES IN AMERICA.

In Chicago there are laid down and in successful operation at present 718 miles of wire, of which the Bankers and Merchants' Telegraph Company own 400 miles; the Postal Telegraph Company, 150; the Chicago Telephone Company, 28; Western Indiana Railroad Company, 50; and the City and Fire Alarm Telegraph, 60. In addition to this, the Western Union will shortly have 500 miles down, and the Baltimore and Ohio 250, making a grand total of 1,468 miles of underground wires. A Bill is now being introduced in the House of Representatives at Harrisburg, U.S.A., which provides for a measure we hope to see made compulsory in this country before very long. The Bill is substantially as follows :—"1. Be it enacted, &c., that all telegraphic, telephonic, and electric light, wires, and cables used in any incorporated city of this commonwealth, having a population of 10,000 or more, shall hereafter be placed under the surface of the streets, lanes, and avenues of said city. 2. Every corporation, association, or person owning, controlling or operating telephonic, electric light or other wires and cables, including what is known as telegraph poles and other appurtenances thereto, shall, before the first day of December, 1885, have the same removed from the surface of all streets, lanes, or avenues in every such city of this commonwealth. 3. In case the owners of the property above enumerated still fail to comply with the provisions of this Act, within the time herein specified and limited, the local governments of the said cities of this commonwealth shall then, and they are hereby directed to remove, without delay, all telegraphic, telephonic, electric light and such other wires, cables, and poles, wherever found above ground, within the corporate limits of their respective cities. 4. No city in this commonwealth shall grant any exclusive privilege or franchise under this Act to any corporation or individual, by which a monopoly may be created or competition prevented on equal terms. 5. That any individual, firm, association, or corporation, or any officer, agent, or *employé* thereof, violating or failing to comply with the provisions of this Act, shall be deemed guilty of a misdemeanour, and, on conviction, shall be punished for each and every offence by a fine of 1,000 dols., one-half to be paid to the prosecutor and the other half to be paid to the county in which the conviction is had, and an imprisonment not exceeding two years, or either or both, at the discretion of the Court. 6. That all laws or parts of laws inconsistent herewith be and the same are hereby repealed."

SULPHUROUS ACID AND TELEGRAPH WIRES.—Between Lassale and Peru, in America, where the Central Union Company have several wires, there are several zinc furnaces in the immediate neighbourhood through which the lines pass. The fumes from these furnaces, which are largely impregnated with sulphurous acid, are very destructive to wires, and a No. 8 wire will last only about three years. A piece of line wire shown, which two years ago was either a No. 12 or 14, had been reduced to nearly a 20 when taken down.

THE ELECTRIC LIGHTING ACT, 1882.

A meeting of the general committee formed to frame amendments of the Electric Lighting Act, 1882, for the consideration of the Board of Trade, was held at the offices of the Anglo-American Brush Electric Light Corporation, Belvedere-road, S.E., on Wednesday, the 11th inst., the Right Hon. Lord Thurlow, chairman of the committee, presiding The report of the executive committee, and a draft Bill amending the Electric Lighting Act, 1882, on the basis of the Gas Acts, were submitted, and the details of the same having been explained, it was resolved unanimously, on the motion of Viscount Anson, that the report of the executive and the draft Bill be received and approved.

The Chairman was then asked to communicate with the President of the Board of Trade with the view to a deputation of the committee attending at the Board ol Trade to learn his views on the proposal of the committee.

The executive having been unanimously re-elected, the proceedings terminated with a vote of thanks to the chairman.

Report of the executive committee, appointed on the 17th day of December, 1884, by the General Committee formed on the suggestion of the President of the Board of Trade, to frame clauses in amendment of the Electric Lighting Act, 1882, and to confer with the Board of Trade as to the terms of the provisional orders and licences.

The executive committee have, after deliberate and careful consideration, arrived unanimously at the conclusion that the electric light companies should demand to be put simply in the same position as the gas companies are, both as regards their privileges and their obligations. The reasons which have led them to adopt this conclusion are—*in the first place*, that they believe no satisfactory solution of the question of general electric lighting can be arrived at by amending the Act on the basis of a modified purchase option clause, the existence of such an option in any form rendering it impossible to attract from time to time fresh capital to the enterprise, or indeed to attract any capital at all; and, *in the second place*, that the conclusion itself is clear and intelligible, and will at once commend itself to the public by its fairness and simplicity.

The executive have decided, after a careful examination of the general Acts and the principal special Acts relating to the gas companies, that the electric light companies may safely undertake the business of general lighting under conditions entirely similar to those of the gas undertakings; and to carry out their recommendation they have prepared the draft of a Bill, which they now submit to the general committee, together with a brief memorandum of objects. The executive have further drawn up the following statement, which they also submit to the general committee, containing in some detail the principal reasons in support of their conclusion, which they think will commend themselves to the public, and which they trust will receive favourable consideration from the Board of Trade.

Reasons.

There are few things in the history of industrial undertakings more striking than the degree in which America has outstripped England in electric lighting. To say that the progress there has been tenfold that in England would be short of the truth.

In a recent lecture by Mr. Preece, F.R.S., who had just returned from America, he mentions that the number of arc lamps in the States is 90,000. In New York there is a central station with over 12,000 incandescent lamps, where the current has been maintained for two years with only two and a-half hours' stoppage. Two larger stations in the upper part of New York are now being set up and will shortly be open. Even small provincial towns in the States have their arc lamps, and there is a village in New Jersey with 1,200 incandescent lamps.

In this country electricity has been a thoroughly practical success in ship lighting, where the industry is untrammelled by authority and conducted on the footing of an ordinary commercial business. In its application to ships, and particularly to those of H.M. navy and the large ocean-going steamers, the electric light is rapidly displacing the use of oil. Manufacturers in this country have also succeeded in creating a consider able demand for their goods for foreign countries and the colonies. Had it not been for such openings their manufacturing plant would have been comparatlvely idle.

Electric lighting in England has succeeded in isolated installations; but house-to-house lighting on a large scale is hampered by the difficulty that it requires a wayleave under the streets, with some power of temporarily disturbing the surface. The Electric Lighting Act, 1882, has laid down the general conditions under which such wayleaves may be obtained, and by implication prohibits the local authorities from granting a wayleave on any other terms. The conditions are most unfair in their character; but so strong was the belief in the success of electric lighting that, after keen competition and many months of hard work, at a cost of many thousands of pounds, several provisional orders under the terms of this Act have been obtained by companies and individuals. Those who succeeded in securing the orders believed that they had thereby obtained valuable concessions; but, on applying the test of negotiating for capital to work the orders, or considering whether they were justified in spending shareholders' money for this purpose, they found that neither would they be justified in calling upon their shareholders for the necessary capital nor could they induce capitalists to provide fresh money for central station lighting on the present conditions.

The result is that not a single central station under these orders is working, or is in course of establishment in London or in any of the large cities in the United Kingdom.

This circumstance has given rise to grave complaints against the Act, not only in England, but also in America. The following is an extract of a letter recently received from the president of the Edison Electric Light Company of New York:—"The almost total collapse of electric lighting in England, together with the assurance which I receive from time to time to the effect that until Parliament reverses its former action, or till it amends the Electric Lighting Bill, no development of central station business can be expected in England, has given us on this side of the Atlantic much serious concern. From the many discussions I have had with scientific English friends visiting this country during the past summer, I have been led to believe that central station, or house-to-house lighting, is deferred into the dim distance of the future by virtue of Mr. Chamberlain's Bill for the *promotion* of electric lighting, and it is hopeless to do anything in this matter till someone introduces and passes a Bill for the *prevention* of the industry."

The principle upon which this Electric Lighting Act, 1882, proceeds is that general electric lighting may be undertaken by local authorities, or by companies, or by private persons; but that if the local authorities, whether because they regard the business as too risky, or from any other cause, decline the venture, and the work is undertaken by companies, the local authority which has refused to avail itself of its chance of undertaking the work at the outset, shall be able after a comparatively short period to acquire upon terms, which it would be a misuse of ordinary language to call purchase, all the property of the undertakers.

General electric lighting requires a large enpenditure of capital; the risks are known to be great, and capitalists must be treated with ordinary fairness to induce them to put money into such an undertaking.

Under the Act, while the earning of a dividend is problematical, it seems that under any circumstances much of the capital must be lost; for if the undertaking fails, this of necessity involves the loss of a great portion of the capital, and if their enterprise is successful the undertakers, instead of being compensated for the risk they have run, will lose a large portion of their capital and be deprived of the management under which that success had been achieved. Moreover, the dread of this unfair and unprecedented purchase option clause will hang over the enterprise and will be the means of arresting its natural growth and development, as it will prevent the application of fresh capital, which would be from time to time required as the system grows in popularity and is improved in economy.

But not only has the purchase option clause deterred capital from the enterprise, it has also furnished the local authorities with a distinct motive for declining the risk of embarking on electric lighting. It is the obvious policy of local authorities, having the option to purchase an undertaking on which they incur no liability, to wait until the risk is undertaken by others, so that they may be in a position to acquire the property only if and when the enterprise has proved successful.

The executive committee are unable to devise any terms of option which shall avoid the double consequence of deterring capital and encouraging local authorities in the policy of abstention.

We have not omitted to observe the hint thrown out by Mr. Chamberlain, that while the community should be enabled to resume this "monopoly" after twenty-one years, it should do so on terms which would at all events fairly recoup the undertakers for all legitimate outlay. If we were to formulate the terms which we should consider necessary *fairly* to recoup the undertakers for all legitimate outlay, including (as we should understand was fair) *compensation for risk*, we should only demonstrate the impossibility of framing a fair purchase option clause which would be workable. If really fair compensation for risk were included in the terms, it would only be in exceptionable cases of success that the option would be of any use. In the majority of cases the option would be illusory, and the clause a dead letter; and if in the exceptional case, where great success has been obtained by good management, the managers are liable to be displaced by the local authority, who may choose to exercise the option to buy them out—though at a high price—we think the condition will be mischievous in its tendency to paralyse the undertaking.

If, on the other hand, it is not meant to include compensation for risk in the terms of purchase, and it is proposed that the unsuccessful undertakings shall bear the loss, while the successful ones are to be bought out on terms which will recoup the undertakers merely in cost price and interest, it is needless to point out that capital cannot be obtained on these terms; the terms would still have the double effect of deterring capital and encouraging local authorities to abstain from the venture at the outset.

The purchase option clause was an experiment, and it has failed. It is absolutely without precedent.

We observe that Mr. Chamberlain said, in answer to the deputation which resulted in the formation of the committee, that there were precisely the same restrictions in the case of tramways to those in the Electric Lighting Act.

That is certainly not the case. To say nothing of the circumstance that in the case of tramways the price is left to arbitration without the prohibition against taking into account *goodwill* (or present profits), the tramway companies will be left in possession of their rolling stock and movable property; and, besides, the Tramways Act contains a very important clause disabling the local authority under any circumstances from working the undertaking. What they acquire by the purchase is the bare property, subject to the virtual obligation to lease the undertaking to some person or body of persons capable of working it. The competition is not likely to be serious. The old company will be in readiness with their rolling stock, movable property, and experience, and will doubtless obtain the lease at a rent representing fair interest for the outlay made by the local authority. It is indeed morally certain that in the case of a tramway, the purchase option clause, if exercised, will make little difference in the situation. The tramway company will retain the management, and probably make little or no sacrifice of annual income.

The conditions of the Electric Lighting Act, 1882, differ fundamentally. If their undertaking has been a disastrous failure, *cadit quæstio*, they bear

Digitized by Google

the loss ; but if it is struggling towards success (the utmost that can be hoped for in twenty-one years' time) the local authority may take the property and assume the management at a price which, if the option is not to be illusory, will be necessarily unfair.

But we further contend that there is no real analogy between the cases of tramways and electric lighting undertakings. There were no intricate scientific questions involved in laying tramways, and it was not difficult to calculate approximately the capital outlay and the cost of working, tramways having been used in other countries before they were introduced here. Moreover, the use made by tramways of the streets and roadways is a very different thing from the use proposed to be made by the electric lighting undertakers. The tramways have a use of many miles of the public roadways which continually and seriously interferes with the ordinary public user of the street, causing much inconvenience and even risk.

Another argument which has been used (though not by Mr. Chamberlain) is that the water companies are now practically masters of the situation, in the supply of one of the first necessities of life, and can only be bought at a very high price. It is not for us to argue the case for the water companies, but it may be pointed out that for many years the profits of the shareholders were by no means excessive. It is also to be remembered that the powers required by the water companies, extending as they do to the absorption of large natural resources, are very different in kind from the simple wayleave and power of temporary disturbance asked by the electric lighting companies.

As to the purchase of the telegraphs by the Government it has been said that the terms were exorbitant. Under the Telegraph Act, 1868, the Postmaster-General was empowered, with the consent of the Treasury, to purchase the telegraphs on the usual terms of expropriation), that is to say (failing agreement) by arbitration. The interests of the telegraph companies were in fact purchased by agreement, but in the case of some (at least) of the railway companies, arbitration was resorted to. The suggestion really resolves itself into a grumble against the awards. It affords no reason why electric lighting undertakers should submit, by anticipation, to be expropriated on unfair terms, and without compensation for risks which are at present incapable of estimation. After all, it does not appear that the purchase of telegraphs has been otherwise than a good commercial bargain for the Government. It is instructive to know that with this fully before them, the Treasury sanctioned the arrangement which has been made between the Postmaster-General and the telephone companies for the compulsory purchase of their undertaking, and which provides that at certain fixed dates the Postmaster-General may give notice to purchase the various exchanges, and the agreement simply provides that the price to be paid shall in case of difference be determined by arbitration under the Common Law Procedure Act. This bargain, it may be remarked in passing, was made after (and notwithstanding) the Post Office had established by legal decision (founded on the terms of the Telegraph Act, 1869) an exclusive privilege against the telephone companies.

It may here be not irrelevant to advert to the option reserved by the Indian Government to purchase the railways. In the case of the Indian railways, the Government *undertook the risk* from the outset, by guaranteeing a permanent 5 per cent. dividend, and the option of purchase was reserved upon average market value, which was itself enhanced and sustained by the guarantee. The case therefore affords no parallel in favour of the option of purchase applied to electric lighting undertakings ; but it is remarkable to find that when the option came to be actually exercised, in the case of the earliest and one of the most successful of these undertakings, the East Indian Railway, so much importance was attached to the object of keeping the management in the hands of those who had formed and developed the enterprise, that special arrangements were made, confirmed by Act of the Imperial Parliament, for the purpose of continuing the management and giving the shareholders the option of retaining an interest in the continued success of the undertaking.

The undertakings which really bear a fair analogy to electric lighting undertakings are those of their rivals, the gas companies. It seems necessary to recall a few of the leading facts in the history of this industry.

Take the case of the Gas Light and Coke Company. This company was formed in 1809, about 16 years after it had been practically demonstrated that a house could be safely lighted by gas. By an Act passed in 1810 the Crown was authorised to grant them a charter giving them privileges for a term of 21 years. This charter was granted on the 30th of April, 1812. To quote from one of their recent reports : "For years the rental was little more than nominal, and when at a later period it had succeeded in forcing itself into a position of some public utility and realising a fitful profit, the shares were almost always at a heavy discount. The dividend, when any was paid, seldom exceeded 6 per cent. The company's manufacture was in its early stage naturally crude and imperfect ; the yield of gas from each ton of coal was very small, and for many years the price remained at about 15s. per 1,000 cubic feet." But in the year 1816 their charter was extended for a further period of thirty years, and in the year 1819 they were incorporated with perpetual rights, and at a subsequent date their dividends were regulated in the manner which has since become univeral. It does not appear that the dividends were regulated at all in the earlier periods of the gas companies, in fact not until the year 1823, that is thirty years after the introduction of gas lighting in a house.

The first gas company formed out of London was at Preston, in Lancashire, in 1816. It commenced with a capital of £2,000 ; in 1817 the capital was £11,000 ; and in 1839, when the company was incorporated, the capital was raised to £30,000. Situated within a few miles of the cannel coal-pits, and with exceptionally favourable local circumstances, they paid a dividend at the rate of 5 per cent. in 1817, none for the years 1818, 1819, and 1820 ; but in 1821 the dividend reached 6 per cent., which was the rate until 1825. It is clear that if the conditions of the Electric Lighting Act had been applied to gas in its infancy, this important and useful industry would have died a natural death in the early part of this century.

The difficulties which gas had in its early times to overcome are greatly enhanced in the case of electric lighting by the circumstance that gas already occupies the field with its enormous fixed plant and invested capital. The position in which the electric lighting companies are placed in this competition is well expressed in the able and important report of the committee of the society called the *Dynamicables*. "Under the existing state of things the legislative conditions are incomparably more favourable to gas than to the electric light, and must enable it to undersell its rival in any competition there may be between them. The gas companies hold their powers in perpetuity, and they can afford a present loss or content themselves with diminished profits for a time in order to get rid of a troublesome competitor, the more so as they are entitled to make up any deficiency in the statutory dividends by increased dividends in future years ; and the profitable nature of gas production would certainly enable them to do so."

It is sufficiently arduous for electric lighting to contend with gas upon conditions similar to those under which gas undertakings are now placed; but these conditions are at least the result of a compromise shown by experience to be possible, between the encouragement of enterprise and the security of the public against an undue use of monopoly.

The existing gas legislation does in effect secure to the community the benefit of whatever profit is earned exceeding what is contemplated by the terms of the Act as a fair remunerative profit upon the original capital embarked in the enterprise. As to new capital, the auction clauses secure that it shall be raised at the minimum market rate ; and any profit above that rate earned on such new capital goes to diminish the price, for the benefit of the consumer within the area.

The auction clauses in the Gas Acts have been well devised for the precise object which the purchase option clause in the Electric Lighting Act was apparently intended to secure. Their operation is self-adjusting, according to the state of progress in the industry. They have succeeded in their object, so that without acting as a deterrent to investors they effectually impose a limit upon profits and give substantial benefit to the consumer.

Moreover the sliding scale applied to gas companies, and by the amended Bill proposed to be applied to electric lighting companies, has restored to the gas companies that incentive to exertion which the hard and fast limit of a maximum dividend had taken away, with the result that such improvements are effected in the manufacture and distribution as to enable the companies to reduce their price, so that at the present time 16-candle gas is sold in London for as little as three shillings per thousand feet, a condition of things there can be no hesitation in saying that would not have been reached had the management been in the hands of public bodies not stimulated to improvement by the hope of pecuniary reward.

The purchase option clause has conspicuously failed, and the executive committee have deliberately formed the conclusion that such failure cannot be remedied by any modification in the terms of the option. We believe that a purchase option clause without a corresponding guarantee, as in the case of the Indian railway contracts, must necessarily fail, inasmuch as without the steady market value which could only be secured by a guarantee, the terms of option, if not illusory, must be deterrent to an extent out of all proportion to the benefit which can possibly accrue to the community.

It can hardly be necessary to argue the general question that in order to develop a nascent industry, and more especially to force it on the public in the face of a rival manufacture already established with a large fixed capital, it is necessary to have all the encouragement which, consistently with the interest of the public, can be safely given to it.

It may, however, be well on this point to remind the committee of the specific evidence which has been given by a great authority upon a parallel question. In the evidence taken before the late Patent Commission, the question had been mooted as to the public utility of the monopoly given by the Patent Laws, Sir Wm. Armstrong having contended that these monopolies have acted as a restraint upon the development of manufactures. The result of the whole evidence was an overwhelming concurrence of opinion as to the utility of patents in assisting the progress of industry by enabling new and important manufactures to become developed in the face of established rivals. The specific evidence referred to is that of Sir Henry (then Mr.) Bessemer. It was to the effect that his own invention—which it is needless to say has been one of the most beneficial and far-reaching advances ever made in industrial progress—would have fallen to the ground had it not been for the inducement held out by Patent Law to expend money in developing his process and forcing it on the trade. In fact, he spent more than £20,000 in developing and perfecting the invention before he could effectually bring his manufactured steel into the market. But for the patent law he could not have found the means of improving the invention so as to be worked commercially. It seems impossible to doubt that if the Bessemer process had been hampered with the condition that any manufacturer wishing to use it had to apply to Parliament for powers, which could only be obtained on terms of putting a fixed period upon his enterprise, the industry would have failed to establish itself, and the enormous economies and improvements effected by it would have been lost.

In the comparison between electric lighting and gas, the one advantage commonly claimed for gas is that of economy. The apparent economy of gas, however, is based on the assumption that the oxygen consumed by the burning of the gas costs nothing. It is estimated that every gas burner consumes as much oxygen as a living person. The large use of gas, even supposing it to be of extreme purity, is therefore necessarily one of the degenerating influences of our crowded cities. It is also to be considered that, owing to the consumption of coal for electric lighting being less than that required for producing an equal amount of light by gas, the resources of this country will, in the event of electric lighting being

Digitized by Google

established on a large scale, be economised and prolonged, an economy which will be materially aided by the circumstance that in many localities water power will be available for electric lighting.

It will no doubt in any case be a long time before electric lighting can exercise a sensible influence in displacing gas. With a fair field of competition, but not without it, this is ultimately possible. A serious competition will in the meantime greatly improve the quality of gas supply, as, indeed, the threat of competition a short time ago did to a very sensible extent.

The executive committee suggest, as another reason for preferring a limit upon the profits of undertakers to a fixed period upon their existence, that limited dividends are more likely to attract steady and genuine investment, but will tend to discourage speculation on exaggerated and unreal expectations. It is indeed possible that on the basis of a fixed period, and unlimited profits in the meantime, a few speculative undertakings may be launched, with the result of disappointment to extravagant expectations, and of rendering it impossible at the critical time to attract fresh capital to the necessary extension of the enterprise.

It is to be remembered that as electric lighting develops and advances in popular estimation, a large and increasing capital will be necessary to extend the system, and make the supply still cheaper and more popular. This will be the critical period, and the ultimate success of electric lighting may not be attained until a large portion of the term of the purchase option clause has expired. It is impossible that the new capital can in the remainder of the term earn a fair commercial profit, as well as the means of providing a sinking fund for replacing the loss. The price loaded with the cost of providing a sinking fund would be prohibitive to extended consumption. Any proposed extension of the enterprise at such a time must necessarily be a failure commercially. The undertakers would be unable to obtain fresh capital in the market, and if there remained any uncalled capital already subscribed, the calls could only be made by a cruel injustice to the shareholders.

If electric lighting undertakings are put on a footing of equality with gas, central station lighting will at least be tried on a scale sufficient to make the competition with gas serious.

The executive committee believe that such undertakings will, through difficulties, achieve ultimate success.

The possibility of electric lighting as a large and popular industry now hangs in the balance, and if the committee should adopt our recommendation to demand that the electric lighting industry shall be put on the same footing as gas, we think it fair that the argument should be respectfully urged on the Board of Trade, that if this reasonable demand is not conceded, upon them will rest the responsibility for the failure of electric lighting in this country, and for the far-reaching consequences which may follow such failure. How far these consequences may extend we cannot presume to speculate. Even at the present moment we believe that the stimulus given to genuine enterprise in electric lighting by putting it on the gas footing would be considerable. If that enterprise succeeds, a further stimulus will be given to the application of science to industry which cannot but be important. Indeed, the encouragement of electric lighting at the present moment might be the turning point in the long-continued depression of trade under which the country has lately been suffering. Having regard to the keenness of competition which has now overtaken the long undisputed lead of this country in industrial progress—having regard to the circumstance that England is already distanced by America in the industry of electric lighting—that this may be a step towards leaving to America a permanent lead in the new applications of science—and that America still holds in reserve the resources of the approaching extinction of her debt and the ultimate adoption of free trade—we think the Board of Trade will attach due weight to the importance of giving at this critical stage a fair field to the development of electric lighting enterprise.

With these larger considerations the committee are not primarily concerned. As representing the interests vitally affected the question for the committee is on what terms we can call for or invite capital to the enterprise of public electric lighting. We must keep in view that the electric lighting industry will in any case remain in possession of the smaller and safer field, which may be exploited on conditions not involving wayleaves through the streets. The electric light companies will continue in possession of the ship-lighting industry, and on land they will be able to conduct electric lighting on a small scale as an expensive luxury for those who are able to pay for it. As to the larger field, if the industry can be worked only on the terms that property which is the result of private money and enterprise of the undertakers—not consisting of an undertaking built upon land the subject of a concession, but as much their own as the property of an insurance company or telegraph construction company which has been obliged to apply to Parliament for powers affecting its constitution—is to be taken from them by the local authority without either a fair bargain or an Act of Expropriation by the Legislature of the day, we, as representing those whose capital is proposed to be at risk, feel bound to pronounce the words *non possumus*. We cannot, we dare not, we will not embark our capital on these terms.

We may point out, however, that the local authorities, without an unfair acquisition of the property of the undertaking, will have, in any case, a large share in its future success. Apart from the considerations of refinement and health to the ratepayers, they will enjoy the substantial advantage of the creation of a considerable rateable property.

Moreover, while unable to accept any purchase option clause, we think it quite right that all reasonable facilities should be given to local authorities to acquire electric lighting undertakings by agreement. A provision of that kind has already been embodied in the Public Health Act with regard to gas, and we have accordingly inserted in our draft Bill a similar provision with regard to electric lighting undertakings. Such a provision will, we think, give local authorities who have declined the risk at the outset, a certain *locus pœnitentiæ* if they are wise in time by offering liberal terms to the undertakers when ultimate success is fairly assured. It is not improbable that at such a time the undertakers may be open to a fair bargain so as to have the opportunity of transferring their capital for the development of electric lighting enterprise in a new field.

THURLOW, Chairman.

London, March, 1885.

ON THE CHARACTERISTIC CURVES AND SURFACES OF INCANDESCENT LAMPS.*

BY J. A. FLEMING, M.A., D.SC. LOND., FELLOW OF ST. JOHN'S COLLEGE, CAMBRIDGE.

Recent issues of a scientific journal† have contained some interesting letters and notes on the life of incandescent lamps, and on resulting deductions to be made therefrom. The difficulty of the full and complete discussion of this subject is the absence of sufficiently prolonged experiments to give statistics reliable for this purpose. These can only be obtained at great expense and by experiments lasting over a considerable time, but the results to hand make a preliminary investigation interesting on the connection which exists between the life of incandescent lamps and the other correlated quantities.

The manufacture of incandescent lamps has now advanced to such a condition that the accidents of manufacture are greatly under control. The conditions necessary to get a good lamp are fairly well understood, and the physical actions going on in the lamps are also to a great extent known. We now know that the expectations of earlier investigation of getting an absolutely unalterable carbon incandescent lamp are not destined to be fulfilled, but we know that the gradual destruction of the filament is an operation dependent upon several causes, which may be greatly delayed by attention to, and success in certain operations of manufacture.

The gradual destruction of the carbon filament in a vacuum lamp is a kind of erosion taking place at one or more points. Observation seems to show that in a single loop filament this cutting through takes place most generally near the negative side. The determining cause of breakage is, however, temperature, and carbon filaments which present such inequalities of resistance as to give rise to spots of higher temperature might, other things being equal, be expected to be doomed to a short career. Lamp filaments are therefore like human lives ; some come into the world with a taint of disease upon them, in the shape of irregularity of structure, which predisposes to an early death ; but, nevertheless, as even in the case of suicide, the great law of averages overrides particular instances, and gives us, in the case of a sufficiently extended series of observations, a law connecting the average behaviour under fixed circumstances.

Experience gained during three years of commercial manufacture and use of incandescent lamps has demonstrated that when a large number of filaments are prepared with identical care, and the lamps made with them sorted out into batches, and worked with varying electromotive force, that there is a very constant relation between the average efficiency or candles per horse-power and the average duration or life, and the working potential or volts of the lamp. Now, in a general way we do not know what the form of the function is that connects these three quantities, or any two of them, but there have been a large number of observations on the relation of certain variables which indicate as a most probable form an exponential function.

There are four variables between which a relation is required—electromotive force, resistance, candle-power, and life. The third of these is at present somewhat vague and indeterminate. What we really are concerned with is the total eye affecting radiation, and our present methods only allow of a certain more or less imperfect comparison of this as a whole with that of a standard candle, or a calculation of the integral deduced from observation of the relative intensities of certain rays. Accordingly, of these four quantities two alone can be measured with any great accuracy. One is merely an average, and the other is necessarily a somewhat ill-defined quantity.

Between any two of these variables we can seek a relation, and having a number of observations we plot down these in what are best called the characteristic curves of the lamp. Now two of the most important of these curves are those connecting the electromotive force and efficiency, or candles per horse-power, and the electromotive force and life, and they may therefore be called the principal characteristic curves of the lamp. Three other useful curves may be obtained by plotting down the curves connecting candle-power and current, candle-power and electromotive force, and electromotive force and resistance. These may be called subsidiary characteristic curves.

Since the life and efficiency of a lamp vary together with the electromotive force, we can only properly represent the relation between the three by a *surface*, which may be called the characteristic surface of the lamp.

Take three rectangular axes, x, y, z (see Fig. 1), and let distances measured outwards represent life, candles per horse-power and electromotive force. Let a curve be drawn on the $y\,x$ plane, representing the relation of electromotive force and life, and one on the $x\,z$ plane, representing electromotive force and efficiency ; let the ordinates be drawn at various points to both the curves, starting from abscissæ, representing certain pressures v_1 v_2, &c. ; complete the rectangle on the ordinates k, l, &c., and we see that these rectangles form the orthogonal sections of a solid bounded respectively by the two planes $x\,y$ and $x\,z$ and two curved

* Read at the Physical Society, 14th March, 1885.

† *The Electrician*, Vol. XIV., 1885, pp. 246, 294, 311, 347.

Digitized by Google

surfaces, of which the characteristic curves l and k are the traces on these planes. The surface of this volume may be called the characteristic surface of the lamp. We see that the area of the orthogonal section parallel to $y\,z$ gradually increases to a maximum, and then decreases. This is obviously because for zero electromotive force life is infinite and candles per horse-power zero ; whilst for very high electromotive force life is zero, and candles per horse-power, or efficiency, a maximum. Now the area of cross section, which is a maximum for a certain value, v_2, of electromotive force, represents the product of life and candles per horse-power, or the maximum candle hours per horse-power it is possible to get, and the value of $k\,l$ is therefore a very important quantity. I shall call this maximum value of $k\,l$ the principal modulus of the lamp, because the value of the lamp for commercial purposes is obtained by dividing the numerical representing the principal modulus by the price of the lamp, taking either the cost of manufacture or the selling price according as the question is considered from a manufacturer's or purchaser's point of view.

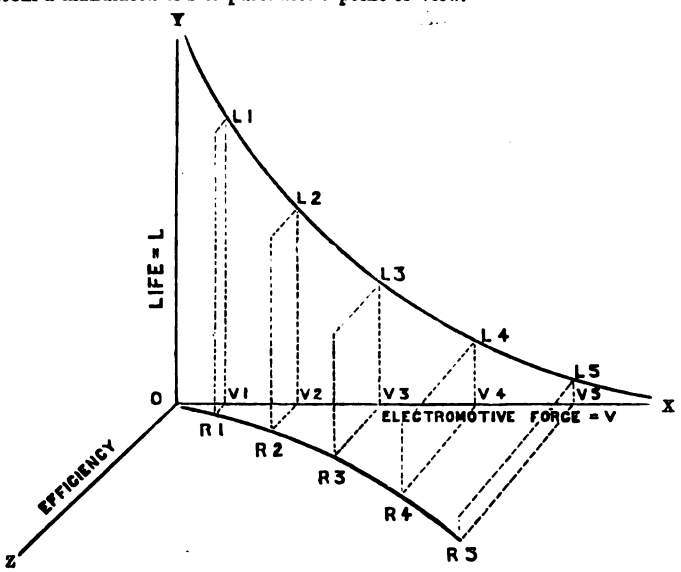

FIG. 1.—Diagram of the principal characteristic curves of a lamp. Efficiency = R.

The product $k\,l$ is itself a function of the electromotive force, and the value of the electromotive force which makes this quantity a maximumis an important one to determine. It is the pressure at which the lamp should be worked in order to realise the greatest quantity of light for a given expenditure of energy in the lamp.

TABLE I.

Volts.	Life.	$\log_{10}$ (volts).	$\log_{10}$ (life).
95	3595	1·97772	3·55570
96	2751	1·98227	3·43949
97	2135	1·98677	3·32940
98	1645	1·99123	3·21617
99	1277	1·99564	3·10619
100	1000	2·00000	3·00000
101	785	2·00432	2·89487
102	601	2·00860	2·77887
103	477	2·01284	2·67852
104	375	2·01703	2·57403
105	284	2·02119	2·45332

Let us next consider the form of the function which expresses these characteristic curves. Take, for instance, the curve of life and electromotive force. We do not know whether this curve is a continuous curve, whether it is assymptotic to axis of y, or, in fact, how it behaves beyond the limits of the values of electromotive force v, for which lamps are incandescent. We have, however, certain values for l corresponding to values of v, not lying far on either side of the ordinary so-called "marked volts" of the lamp. When the writer was in America he was shown a large number of observations made with the view of determining the relation between average life and electromotive force, not far on either side of 100 volts taken for the Edison 108 volt A lamp. For this lamp the life pressure curve at or near the working pressure is approximately a logarithmic curve, whose equation is

$$l = A v^{-a}$$

when A and a are constants, and for the Edison 16-candle 105 volt lamp a is nearly twenty-five ; and accordingly life varies inversely as the twenty-fifth power, roughly, of the electromotive force. In the figures shown to the writer the life-pressure curve had been drawn for pressures corresponding to lives far in excess of what could actually have been observed during the time filament lamps have been made, reaching up to 11,793 hours. This is obviously improper. We do not know that a is not itself a function of v, and for pressures departing far from the ordinary working pressure, the variation of average life and pressure is not probably expressed by so simple a relation, and we cannot go fairly beyond the limits of actually observed lives M. Foussat has recently communicated to a scientific journal the results of observations on the life of French Edison lamps.

Now, the figures given by M. G Foussat, on p. 246 of *The Electrician* for 1885, stated to be the result of a large number of observations on the relation of average life and pressure, at or near 100 volts, conform approximately to the above law. Taking M. Foussat's numbers for life and electromotive force, and taking logarithms of both we have the figures given in Table I. (in preceding column).

Writing down the differences between successive values of $\log v$ and $\log l$ we get the numbers :—

455 11621	432 10513
450 11009	428 11600
446 11323	424 10035
441 10998	419 10449
436 10619	416 12071

Now, if $l = A\,v^{-a}$ $\log l - \log l_1 = -a(\log A\,v - \log A\,v_1)$, where l and l_1 v and v_1 are adjacent values of l and v, accordingly

$$a = -\frac{\log l - \log l_1}{\log A\,v - \log A\,v_1}.$$

The mean of the differences of $\log l$ divided by the mean of the differences of $\log v$ gives 25·4 nearly, and accordingly M. Foussat's numbers agree with those found in America in assinging to a a value not far from twenty-five for the Edison lamp. In the neighbourhood of 100 volts

$$l = A\,v^{-25}$$

or average life varies inversely as the twenty-fifth power of electromotive force.

This, however, is easily seen to be a very rough approximation. The successive quotients of life difference by volt difference are not constant, and the above simple exponential formula can not be admitted as anything more than a very imperfect connection. In examining the Carlisle tables of mortality which give the expectation of life at every age drawn from a very large number of observations, it was apparent that an empirical formula, connecting the two quantities could be obtained of a form

$$\log e = a + b\,x + c\,x^2 + \&c.,^*$$

when e = expectation of life at any age x. I was led therefore to try if such an empirical formula better suited the present case, and a process of trial and failure showed that

$$10 \log l = 135 - v - \frac{v^2}{2{,}000}$$

is a formula which gives very nearly correct results in calculating the life of a lamp, l, given the working pressure v in volts. This may be expressed otherwise :—

$$\log l = 13{\cdot}5 - \frac{v}{10} - \frac{v^2}{20{,}000},$$

or

$$l = 10^{13{\cdot}5 - {\cdot}1v - {\cdot}00005\,v^2}.$$

Calculating by this formula, we get the following values for $\log l$ and l, l being the average life in hours of the 100 volt Edison lamp as made in France :—

Calculated by formula.		Observed.	
l	$\log l$	$\log l$	l
3539	3·5488	3·5557	3595
2749	3·4392	3·4395	2751
2136	3·3296	3·3294	2135
1658	3·2196	3·2167	1645
1289	3·1100	3·1062	1277
1000	3·0000	3·0000	1000
776	2·8900	2·8948	785
602	2·7798	2·7788	601
467	2·6698	2·6785	477
362	2·5592	2·5740	375
281	2·4488	2·4533	284

It is evident, then, that the simple exponential function does not give nearly as good results as a formula of this latter description, and there is no doubt but that by a suitable selection of constants, a formula can be obtained expressing the life of the lamp as a function of electromotive force throughout an observed range, which shall be closely in accordance with observed facts.† Until, however, a much larger collection of statistics

* Let x be the age, and e the expectation of life at that age. Then, by the Carlisle tables of mortality, at the several ages—10, 20, 30, 40, 50, 60, 70, 80, 90, the corresponding expectations of life are—48·82, 41·46, 34·34, 27·61, 21·11, 14·34, 9·18, 5·51, 3·28 ; and it can easily be found that $10 \log e = 17{\cdot}2 - \frac{x}{100} - \frac{14}{10{,}000}\,x^2$ very nearly, the calculated values from which are—49·6, 44, 36·6, 28·6, 20·9, 14·3, 9·64, 5·54, 3·14.

† Mr. F. M. Wright has given, in *The Electrician*, p. 311, 1885, a formula,

$$100 - V = 9{\cdot}098213 \log \frac{L}{1000}$$

This is equivalent to

$$9{\cdot}09 \log L = 127 - V$$

and Professors Ayrton and Perry have given

$$L = 10^{14 - {\cdot}11v}$$

or

$$10 \log L = 140 - 1{\cdot}1v$$

both of which are nearly equivalent to the formula given in the text.

Digitized by Google

is obtained we shall not be in any position to determine if these constants are definite for each type of lamp or kind of carbon, and whether the average life of a lamp can be predicted from a knowledge of these constants.

(TO BE CONTINUED.)

PHYSICAL SOCIETY.—March 14.

Professor Guthrie, President, in the chair.

Captain ABNY read a paper upon "Recent Researches on Radiation." In general a hot body loses heat in three ways—by conduction, by convection, and by radiation. In the case of the carbon filament of an incandescent lamp the loss of heat by conduction is insignificant, and a series of experiments has been made to determine the amount of radiation, that is the energy expended as radiant heat for every unit of electrical energy expended in the lamp. Mr. Crookes has investigated the subject of radiation in high vacua, the cooling bodies being thermometer bulbs, and has come to the conclusion that at pressures between 40 millionths and one millionth of an atmosphere the radiation varies as the mean molecular free path. On the author's experiments incandescent lamps of thin glass fibre exhausted to different degrees, the radiation being measured by a thermopile, it was found that at from 40 millionths to 10 millionths of an atmosphere the radiation increases uniformly with decrease of pressure, but that beyond this point it becomes nearly constant. A more important question is to determine the amount of radiation for any particular ray under the above conditions. This was effected by placing a small thermopile in the different parts of the spectrum. Plotting the results with watts as abscissæ, and radiation as ordinates, the curves for each kind of ray are found to be very accurately hyperbolas with vertical axes. This result gives a method for rendering identical the quality of the light emitted by two lamps. We have only to find the radiation corresponding to a particular kind of light for one lamp, and then by examining the curve corresponding to that ray for the other lamp, find for what number of watts the radiation is the same.

Professor J. A. FLEMING read a paper on "Characteristic Curves of Incandescent Lamps," which we shall give elsewhere.

Mr. C. CLEMINSHAW described some "Further Experiments in Spectrum Analysis." These consisted of methods of obtaining the inversion of the sodium line in the spectrum of the limelight. The first consisted in concentrating the rays from the slit by a lens, just beyond the focus of which is a spoon, in which sodium is ignited by a Bunsen flame. In the second method the burner and sodium are introduced between the lime and the slit, and carbonic acid is introduced into the flame. The result in either case is to cause the immersion of the D line.

Professor GUTHRIE, alluding to the pale blue flame produced by common salt in a coal fire, suggested that there might be more than a mere mechanical action produced by the carbonic acid. Mr. Cleminshaw, however, believed that the action was purely mechanical.

An abstract of a communication by Dr. John Hopkinson on "Sir W. Thomson's Quadrant Electrometer" was read by the secretary. According to Maxwell the depression produced by a given difference of potential between the quadrants is given by the formula

$$d=\lambda\,(A-B)\left(C-\frac{A+B}{2}\right)$$

where A and B are the potentials of the quadrants, and C that of the needle. Dr. Hopkinson finds, however, that the constant λ should be $\frac{\lambda}{1+kC^2}$, the quantity k being due to and depending on the unsymmetrical position of the needle with respect to the quadrants.

COMPANIES' MEETINGS & REPORTS.

South Eastern (Brush) Electric Light and Power Company (Limited).

In compliance with a requisition made by certain shareholders of the Company, an extraordinary general meeting was held on the 13th inst., at the offices, 68A, Cow Cross-street, E.C., for considering the following resolutions proposed by such requisition :—(1) That the Company be wound up voluntarily. (2) That Charles Hay Stewart, of Leadenhall-chambers, St. Mary-axe, London, and Alexander Leith Riddell, of 27, Austin Friars, London, be appointed voluntary liquidators of the said Company.

The SECRETARY (Mr. George Offor, jun.), having read the notice convening the meeting, as above,

The CHAIRMAN said: Gentlemen, we have reached to-day a very important crisis in the affairs of this Company, and it is for you to say whether it should be put an end to suddenly and, as I think, ignominiously, or whether you will allow time for it to go out of existence with something like credit and dignity. I do not suppose that I shall influence the vote of anyone who has come here with his mind made up. Those who are bent on self-destruction seldom, I believe, listen to reason; but I have this to say for the benefit of those who are not present—that the position in which we find ourselves now—and that condition of things which has been brought about by those who are opposing the Board—has left the Company a very poor chance of realising the assets we possess. Those who have taken upon themselves to advise the shareholders have announced publicly that the chance of making any terms that would be beneficial to the Company is beyond reasonable expectation, and we have also heard from the same quarter that the chance of selling the Colchester installation is—because it does not happen to pay at the moment—a thing we cannot expect. Now, we think otherwise. With regard to that Colchester installation, whatever may be thought of it, we say we have proved to demonstration the success of our system. All that is wanted is the more extended application of that system to make it a commercial success. With regard to the approach which we are about to make to the Brush Company, though we were told at our last meeting by one who I think should have known better—by a director of that company—that he was authorised to say that they would have nothing to do with us—[A Voice: Quite right.]—well, perhaps by this time Mr. Joseph Braithwaite has found out that when he speaks of his being authorised to act for his company that that is not the case. We have now a communication from the Brush Company, and are to wait upon them next Wednesday, at the invitation of the Board of that company, to consider what terms can be made with them. In addition to that, we have been approached by those who are anxious to take over our work at Colchester. Whether anything will come of that I cannot say; but those who are interested in electric light companies do not desire—and I think they should not—that this Company should be wiped out of existence in the way proposed. There is an aspect of the question which I think is very important—that is, how will our proceedings affect the interests of other electric light companies, and how will they affect the public? I take it that all electric light companies are at the present moment on their trial, and whatever may be the faith of the public now, every successive failure will weaken that faith, and the chance of any other company being successful will in the future be lessened. Personally I should be very pleased, and so no doubt would my brother Directors, to get rid of the trouble and anxiety which attend the performance of our duties as Directors of this Company. We have attended to those duties really for more than a year without fee or reward. We cannot, however, retire from our position in the way now proposed. We take a different ground. We suggest the way we should do it, but we do not accept, and do not believe the required majority will accept, the proposal to wipe out the Company in the way proposed. I would now leave any one of the malcontents to move the resolutions of which they have given notice.

In reply to Mr. LEE,

The CHAIRMAN stated that the requisition had been signed by shareholders of quite sufficient holding for the purpose.

Mr. W. HEWETT, junior, said he would not waste their time by going over the ground which had been already covered. The directors and the shareholders, as represented by the requisitionists, were at issue as to the management of the Company, and especially in connection with the Colchester business. The requisitionists held a considerable number of the shares. He held 500 shares. His friend, Mr. Reginald Braithwaite, held 1,500, and altogether they had a considerable number of the shareholders with them.

Mr. LEE: Mr. Braithwaite was the original broker of the Company.

Mr. HEWETT repeated that it was not worth while going over the ground. Mr. Fry, however, had referred to what was said at the last meeting—that the Brush Company would not look at their assets. As to that he thought that the Directors were perfectly well aware that the Company parted with their interest to the Brush Company some time ago, and they had nothing therefore to offer to that company. (The Chairman dissented.) As for the Colchester installation, he would only ask them as men of business if they could expect any sane man to buy a thing which was a dead loss of £1,000 a year at once, and situated in a country town where they could have no possible prospect of getting a sufficient number of lights to pay them. It was an ill-judged thing to go Colchester, and he believed that the Board were now aware that that was so. If they were not the shareholders, at all events, were. He concluded by moving the first resolution, for the voluntary winding up of the Company.

Mr. NOEL seconded the motion.

Mr. OFFOR thought the Chairman would allow him to explain the nature of the agreement made by the Company with the Brush Corporation, and which had been termed the selling of their birthright. The agreement made was this: Under their original arrangement they had the exclusive right of selling the Brush patents in the three counties of Kent, Surrey, and Essex, and they were to receive 20 per cent. discount on anything they sold. They were, however, prevented by that agreement from dealing in any other dynamo machines or lamps except those under the Brush patents. They were therefore restricted entirely in their business to the Brush patents. The new arrangement they made with the Brush Company was this: In the first place, that Company increased the discount allowed by them from 20 per cent. by an additional 10 per cent. on anything they sold under the Brush patents. They had also given them the privilege of purchasing dynamos or lamps from anyone else, so that if they had a customer who preferred a dynamo machine or lamp of another maker the Company were not prevented from getting their profit out of that transaction. In exchange for these advantages they had allowed the Brush Corporation to sell in the districts of this Company, subject to their giving the Company a commission of 10 per cent. The opinion of the Directors was, that so far from that arrangement being a selling of their birthright, it was an absolute advantage to the Company in having made the new agreement.

Mr. BLEWITT said that the shareholders would perhaps let him explain that the advantage to the shareholders of having got rid of the first arrangement with the Brush Corporation was that the Company had made a capital expenditure of over £7,000 and incurred an annual loss of £1,000.

The CHAIRMAN: That is not an explanation; it is a statement.

Mr. LEE said he would not move an amendment or anything of that kind, as they could express their dissent by a negative. He thought, however, it was simply due to the Directors to say—as they were all of them aware—that the Company was engaged in a new industry, and that

Digitized by Google

the Board had had, in conjunction with all the companies, very considerable difficulties to contend with.

Mr. BROOKER: Oh, we have heard all that before.

The CHAIRMAN: Go on, Mr. Lee. He is perfectly harmless.

MR. BROOKER: Some of the mud will stick.

Mr. LEE (continuing) said he was simply an original shareholder, and he held only 25 shares. He had lost a great deal of money in connection with the other companies. He hoped to live to see a considerable development of electric lighting, and with respect to that desire he thought he had been helped considerably by the South Eastern Brush Company, more particularly in connection with the despised Colchester installation. He desired to get as much of his money back as he could if the concern went into liquidation, or he was quite content to sacrifice what he had lost or might lose so that he might have the opportunity of seeing a very considerable development of electric lighting. He thought that some of the shareholders had been rather misled —he, for one, had been very considerably—in taking up shares in the Company by the highly respectable brokers whose names appeared in the prospectus (Messrs. Foster, Braithwaite and Co.) He had known that firm for many years, and he believed if they were to canvass all the original shareholders it would be found that the name of the firm had been a considerable inducement to take up the shares. Fortunately he was not a large shareholder, whereas he understood that Mr. Braithwaite was interested to a very large extent. At the same time it seemed to him a little out of place for one of the principal promoters of the Company [No, no] to be one of the requisitionists. He said advisedly a promoter, for he considered that everyone whose name appeared on the prospectus was a promoter of the Company. He wanted to see the electric light develop, and he intended to vote against the resolution, not so much, perhaps, in his own interest as in the interest of electric lighting.

Mr. C. H. STEWART said he was not one of those who wished to treat lightly the assets of this Company, and if he were appointed one of the liquidators he would do his utmost to get the outside sum possible from the parent Company. He would also take steps to try to sell the Colchester installation, either to the Corporation, the gas company, or to a private company. He believed that the sooner the Company was wound up the better. That proceeding, he maintained, would not interfere in the least with the course of electric lighting. He had been informed by the manager—whose knowledge of electric lighting he regarded as second to none—that if the two companies were disposed of [referring to the South Eastern and the Provincial Companies] he could do as much business with the Consolidated Company as with them. Besides all that the South Eastern Company was denuded of capital. It had been handed over to the Consolidated Company. They had only 7s. 6d. a share to call up. Where were their means to extend electric lighting? It was their interest to get all they could out of the Company. He said not a word against the Directors, who had come into the business in a somewhat similar way to himself. They had all been sufferers. No doubt the Directors were handsomely paid for two years, but it could not be expected that men of business would work unless they were paid. He hoped the Board would go with the requisitionists as to the liquidation of the Company, and follow with the Provincial Company in which they were all closely interested.

Mr. ALFRED W. LIGHTBODY said he believed the Anglo-American Brush Corporation had lately entered into certain arrangements with some of their subsidiary companies; he referred to the Great Western and the Midland Companies. The meeting had the advantage of having among them one of the Directors of the Brush Corporation, and he would like to ask whether any, and what, suggestions had been made by that Corporation for taking over this Company in the same way as they had taken over—or were about to take over—the businesses of the Great Western and the Midland Companies. He would also ask whether the Brush Corporation proposed any arrangement. Probably these questions could be easily answered by Mr. Braithwaite, and he thought the shareholders would like to have this information before they decided whether the Company should be wound up now, or whether that course should be taken after a certain period, which would give time for such arrangements as he had suggested with the Brush Corporation. If such arrangements were considered satisfactory, they could then be submitted to the shareholders to decide whether they should be carried out or not. The fact of the Company going into liquidation would, he thought, cramp its chances.

Mr. BRAITHWAITE: No.

The CHAIRMAN: Mr. Braithwaite is not an authority

Mr. LIGHTBODY maintained that a liquidation would cramp the chances of realising any assets which the Company might have. He feared that the assets were not very great, but for all that he did not see why all the assets, or the majority of them, should be spent in a liquidation of the Company. If there were a chance of realising the assets they possessed, he considered that the proceeds should go into the pockets of the shareholders.

The CHAIRMAN repeated that they had received a letter from the secretary of the Brush Corporation, and that they had an appointment with the Directors of that company for next Wednesday.

Mr. LIGHTBODY said he was only a very small shareholder, but he did feel an interest in the progress of the electric light.

Mr. JOSEPH BRAITHWAITE said it was quite true that an appointment had been made by the Directors to meet the Board of the Brush Corporation; but, as he stated at their last meeting, he was authorised to say that they saw no prospect of taking over this Company in the same way as the Great Western and the Midland Companies were taken over. The South Eastern Company had parted with their concessions, and the Great Western and the Midland Companies had not. He also wished to say that the Directors of the Brush Corporation would be much more ready—certainly quite as ready—to make an arrangement with the liquidators of the Company as with the Board. Speaking as a shareholder of the Company, and not as a Director of the Brush Corporation, he thought they would stand a better chance of recovering what was lost by acting with independent parties than with the Directors.

The CHAIRMAN asked Mr. Lightbody whether the act of going into liquidation would not cancel the licenses of the Company; and how in that case could they expect to get anything from the Brush Corporation?

Mr. LIGHTBODY thought that this view was substantially correct. He understood Mr. Braithwaite to say that the position of the South Eastern Company was different to that of the Great Western and the Midland Companies. He wished to ask whether it was not the fact, when the Brush Corporation entered into negotiations with the Great Western and the Midland Companies, that a similar arrangement—whereby their original licenses had been modified—had been entered into with the Great Western and the Midland Companies?

Mr. BRAITHWAITE stated that as he was Chairman of the Great Western Company, and was interested in the Midland Company, he could say that that was not the fact. He wished to add, speaking for the Directors of the Brush Company, that they would, in the event of any arrangement, give quite as favourable terms to the liquidators as to the present Board.

Admiral Sir E. A. INGLEFIELD asked whether it was not the fact that when they decided on liquidation their licences would become forfeited.

The CHAIRMAN replied in the affirmative.

Mr. BLEWITT said that the Board, as he understood, had already given a pledge that they would try and sell their concessions to the Brush Corporation, and the Colchester Installation, and failing that, that they would wind up. They would therefore go to the Brush Corporation and say: "We wish to sell you our concessions, and if you do not take them we shall wind up."

The CHAIRMAN: That does not follow, and if it did it falls short of winding up first and then going to the Brush Corporation.

Mr. DUFFIN would like to know, if the Brush Corporation (the parent company) had the full right of supply in the districts in which this Company worked—and for which they gave a large price—what was left of their concessions.

A DIRECTOR pointed out that the privilege of the Brush Corporation of selling in the districts of this Company was exercised subject to their paying this Company a commission of 10 per cent.

Mr. DUFFIN: Then practically they are worth nothing. We have given back what we purchased, and they will not give us anything for our assets.

The CHAIRMAN stated that he would now proceed to take the vote on the first question, and in taking the division he must have due regard to the proportion of votes given. It would require a majority of three-fourths of the votes; but there could be a poll. He then put the resolution, in favour of which eleven voted, eight being against it. He, however, declared it lost, and a poll was demanded.

In reply to a question by Mr. BLEWITT,

The CHAIRMAN stated that he should rule that if the first resolution were carried the second resolution would require the same majority of three-fourths of the votes.

Mr. BLEWITT observed that over and over again at meetings called for winding up liquidators had been appointed by a bare majority.

Mr. HEWETT then proposed the second resolution, appointing Messrs. C. H. Stewart and A. L. Riddell liquidators. He would only remark that his friend, Mr. Stewart, was successful as liquidator of the Great Western Company in returning the shareholders a great deal more than they were ever likely to get out of this Company.

Mr. NOEL seconded the motion.

The CHAIRMAN put it, and announced that twelve had voted for it and six against it. He, however, as before, on the same principle, declared it lost, and announced that they would now proceed to the poll.

Mr. BLEWITT presumed that the Chairman already knew pretty well what the result of the poll would be.

The CHAIRMAN: Yes; but we had better go to the poll. There are represented 11,522 shares. You hold proxies for 6,965, and the Directors have proxies for 4,557.

Admiral Sir E. A. INGLEFIELD asked whether the Directors would agree on behalf of the shareholders to allow one of the members present to join them as a liquidator, and as a sort of guarantee to them that they should know what was going on at the Board, and have some voice. As matters now stood, the Directors had appointed themselves as liquidators.

The CHAIRMAN: No; this will have to be gone over again.

Admiral INGLEFIELD: Who are the liquidators if you wind up?

The CHAIRMAN: Personally, if it goes into liquidation I would rather leave it to some one outside. I do not speak for the Board generally.

Mr. LIGHTBODY thought the Directors should be very pleased indeed to have some one of the opposing shareholders among them.

The CHAIRMAN: We have met the committee of investigation, and Mr. Stewart will bear me out in saying that the Directors were ready to do that—to join with them, and that he and I should be the liquidators; but instead of seeing us again on the subject they sent out this requisition.

Mr. STEWART observed that, so far as he was personally concerned, he would have been pleased with that. He thought it ought to be understood that the Company would be liquidated, and that no further calls would be made.

The CHAIRMAN: I make no promise on that. You may have driven us to it.

A SHAREHOLDER: Do I understand that you are not pledged to the liquidation of the Company?

The CHAIRMAN: You need not understand anything beyond what has been pledged to you.

A SHAREHOLDER: Assuming that the resolution for the liquidation of the Company is lost, are you going to wind up the Company?

The CHAIRMAN: We have said so. It comes to that, but we do not do it it in the way now proposed.

Admiral INGLEFIELD: Is it not the case, notwithstanding these meetings, that this Company will go on as if there had been no committee?

Digitized by Google

The CHAIRMAN: Certainly not. We are going to the Brush Corporation, and we are going to deal with people to sell the Colchester installation.

Mr. LIGHTBODY asked whether the Directors still held to what they had said in their circular. That said:—"The Directors repeat, and are ready to fulfil, the pledge given by them in their circular of the 21st ult., viz.: 'To use their best endeavours to make terms with the Anglo-American Brush Corporation; to try to sell the Colchester Installation as a going concern; or, with the consent of the Board of Trade, to remove the plant elsewhere; and then, at an early date, to wind up the Company voluntarily.'"

The CHAIRMAN: Yes, as early as possible.

Mr. LIGHTBODY: That means to say within a reasonable time.

The CHAIRMAN: If we fail in the course of a few weeks to do anything else, we must proceed to wind up.

Mr. BLEWITT said the Directors would pledge themselves to no date.

The CHAIRMAN: We could not; we are under contracts, and so on.

The poll was then taken, and on the return of the scrutineers,

Mr. BLEWITT said that according to his calculation the requisionists wanted 8,013 votes to have the required majority, and they had obtained 6,965.

The CHAIRMAN said that they claimed 450 more, but as it did not affect the position the matter was of no consequence.

Mr. BLEWITT: This claim is not allowed, because I say that persons who have given bills for calls have not paid them.

The CHAIRMAN: If we give them up it does not affect the question. On this result, accepting Mr. Blewitt's figures, I declare the resolution lost, there not being the required majority.

Mr. NOEL: The result is that the Directors, being in a minority of some 3,000 votes, elect to remain on the Board.

The proceedings then terminated.

Australasian Electric Light, Power, and Storage Company.

As reported in our last issue, the result of the meeting of the above Company, on the 9th inst., was a demand for a poll on the motion for the adoption of the report and accounts. It was arranged that the poll should be taken on the 16th inst., which was done. The report of the scrutineers, Mr. J. H. Duncan (the Secretary of the Company) and Mr. R. E. Stephens, has just been circulated among the shareholders, from which it appears that the result of the poll was as follows:—In favour of the Chairman's motion, 13,406 shares, entitled to 13,146 votes; against it, 1,010 shares, entitled to 1,010 votes, showing a majority in favour of the motion of 12,396 shares, entitled to 12,136 votes. In favour of the motion were included 3,663 vendors' shares. The scrutineers had rejected as invalid, through informality of proxy, 1,697 votes in favour of the motion, and 2,057 votes against it. In a circular accompanying this report Mr. Duncan, on behalf of the Directors, points out that the result of the poll gives a majority for the Board of 12,136 votes, or of 11,776, "if all the invalidated votes be taken into account. The Directors, in announcing the result of the poll, desire me to thank the shareholders for the strong support given to them." The circular adds:—"The original Directors repeat their regret that the committee, although nominated as a consultative body, formed their conclusions without conference with the Directors, without affording them the opportunity of giving any explanations, and without perusing the correspondence. They willingly accept the statement of the committee that this was done in the exercise of their best judgment as to the intention of their appointment. Their report thus assumed, however, an *ex parte* character, and the Directors, therefore, did not feel it incumbent on them to act upon their suggestions. The poll just taken having now disposed of the recommendations of the committee, I am desired to add that the original Directors take this opportunity of carrying out their repeatedly-expressed intention of dealing with the question of the fees standing in the suspense account, which have now been entirely written off, and the same principle will of course guide the Directors in the future."

The German Union Telegraph and Trust Company (Limited).

Report of the Directors to be presented to the shareholders at the fourteenth ordinary general meeting on the 25th inst:—The Directors beg to submit the accounts and balance-sheet for the twelve months, ending 31st December, 1884, including in the accounts the coupon in respect of that period just received from the German Union Company of Berlin. The total receipts during the twelve months amount to £12,460 6s. 2d., which, with a balance of £1 15s. 1d. brought forward from last account, make a total of £12,462 1s. 3d. The expenses for the same period amount to £786 18s. 6d.; of this sum £750 is provided by the German Union Company of Berlin. Out of the receipts an interim dividend of 5s. 9d. per share was distributed on the 20th January last, and the Directors recommend the payment of a further dividend of 5s. 6d. per share, making a total distribution for the year of 11s. 3d. per share, free of income tax, or at the rate of £5 12s. 6d. per centum per annum, as against £5 17s. 6d. paid last year, leaving a balance of £155 7s. 9d. to be carried over to the next acccount. Although the traffic has shown a small increase in the number of telegrams during 1884, there has been a decrease in the average number of words contained in each message, a condition of things which has been experienced by all Submarine Telegraph Companies. The decrease in the number of words has produced a diminution in the receipts, which is not compensated for by the increase in the number of telegrams sent. The cables are in good working order. The establishment of a repeating station at Lowestoft has proved of great advantage in facilitating telegraphic traffic between Germany and Great Britain. With the additions made annually to the reserve and renewal funds of the Berlin Company, these items now stand at over £50,000. Further accumulations to these funds will give a reserve, which will be a solid basis for the Company's future. According to the Articles of Association, Count Oscar von Reichenbach, one of the Directors of the Company, retires by rotation, and offers himself for re-elecion. The auditor, Mr. Henry Dever, also retires, and offers himself for re-election.

Messrs. Glover and Co.—We are requested to mention that on the 20th instant Messrs. Walter T. Glover and Co., electrical wire and cable makers, removed from their present city offices at 25, Booth Street, Manchester, to their new and commodious offices in close proximity to their Bridgewater-street, Broughton-road, Salford Electric Wire Works, Springfield Lane Cable Works, Salford. Their new postal address will be "Walter T. Glover and Co., Salford, Manchester."

PRACTICAL ELECTRICIAN REQUIRED to take charge of the Electrical Department of the ÆOLUS WATERSPRAY COMPANY.—Apply personally, with testimonials, at 235, High Holborn, before 12 o'clock.

ELECTRICAL.—WANTED, a Gentleman understanding Electrical matters, to join Advertiser in FITTING UP a SMALL FACTORY for Electrical Apparatus abroad, on the Mediterranean. Magnificent climate. An Engineer or Experienced Man preferred. Capital required, £1,000.—Address, PIONEER, at Horncastle's Central Advertisement Offices, 61, Cheapside, London, E.C.

ELECTRICAL ENGINEER is DISENGAGED. Has had considerable experience in Electric Light Installations, Land and Ship, in manufacture of Dynamos, Accumulators, &c.—Address S. J., *The Electrician* Office.

Digitized by Google

NOTES.

ELECTRICITY IN AMERICA.—Last year's patents granted in the United States numbered 18,799, of which 1,166 were for electrical inventions.

ELECTRIC LIGHTING AT VIENNA.—The *Wiener Zeitung* announces that M. Fischer has obtained a concession for a central electric lighting station in that city.

TELEGRAPHIC EXTENSION IN LEEDS.—The Post Office authorities are about to establish telegraphic communication between Featherstone Station and the Purston Post Office.

THE CONTROL OF TELEPHONE AND TELEGRAPH WIRES.—We think it better, in the interest of our readers, to give a *resumé* of the proceedings of the committee on this question at the conclusion of the inquiry.

ITALY AND THE RED SEA.—The Italian Minister of War has ordered seven telephonic apparatus to be sent to Massowah to open a communication between the Commander-in-Chief of the expedition and the advanced forts.

SMELTING BY ELECTRICITY.—We are informed that an American engineer has succeeded in evolving a process by which gold, silver and copper can be instantly smelted from concentrations by electric currents of high tension.

THE TELEPHONE AT SAN DOMINGO.—A telephone exchange is about to be established in Puerto Plata. Only copper wire will be used in the establishment of the telephone plant, iron or steel wire being considered unsuitable for the climate.

THE NEW BRIDGE OVER THE GANGES.—The electric light has been adopted by the engineers engaged in the construction of the Gandak Bridge, in order that the work may not be interrupted by the want of an efficient illuminant at nightfall.

THE ANTWERP INTERNATIONAL EXHIBITION. — Messrs. Siemens and Halske, of Berlin, have offered to illuminate the German Section gratuitously by the electric light; and others will light the machine gallery, the central gallery, and the gardens.

THE TELEPHONE IN BATH.—The lessee of the Bath Theatre has consented to allow the committee of the Industrial and Fine Arts Exhibition to place the telephone apparatus upon the theatre stage, which it is proposed to connect to the exhibition building.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 20th March were £2,562, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

"SELL'S DICTIONARY OF [THE WORLD'S PRESS."—Mr. Henry Sell has just issued the 1885 edition of his handy book of reference. It abounds in practical advice to pressmen, to advertisers, and to those of the general public who are interested in journalism.

THE ELECTRIC LIGHT IN NEW ENGLAND.—The American Electric and Illuminating Company have combined with the Edison people, and are to use the Edison incandescent system for isolated lighting in connection with all of their arc lighting stations in New England.

ANOTHER INSTALLATION.—Messrs. S. W. Silver and Co. announce that the rebuilding of their warehouse in Cornhill is now completed, and that their address is again Sun-court, 67, Cornhill, London, E.C. The new building will be lighted throughout with the electric light.

THE ELECTRIC LIGHT AND WARFARE.—*The Times* correspondent, telegraphing from Suakin on Monday, says:—"The electric light from the 'Dolphin' in the harbour, six miles away, is visible at intervals. As its long and brilliant beam sweeps around the plain and over us it cheers our hearts."

ELECTRIC LIGHTING FOR MINES.—In some experiments carried out by the officers of the Regimental School in Versailles it was shown that the incandescent lamps used in the lighting of subterranean passages were capable of resisting the concussion caused by the explosion of 500 kilog. (1,100lb.) of powder.

THE PROGRESS OF CIVILISATION IN THE SOUDAN.—Shortly after the correspondent of the *Daily Chronicle* got his first message through from the field on Monday the wire was cut in no fewer than six places by the rebels in the rear, who had not previously been accredited with knowing anything about the uses of a field telegraph.

THE CABLE SHIP "MACKAY-BENNETT."—This steamer has recently passed through the centre of a terrible hurricane, which lasted six hours. The officers unite in declaring her to be a handsome craft and a magnificent sea boat, and one of the finest specimens of modern marine architecture. She steams 11 to 12 knots an hour.

THE SNOW STORM.—Considerable damage was done on the 22nd by the snow in the neighbourhood of Portsmouth, particularly to the telegraph wires. All communication with the west of England was temporarily cut off, nearly every wire leading out of Portsmouth was broken, and in some instances iron telephone poles were snapped.

THE EARTH'S MAGNETISM.—Gaus, the illustrious German astronomer, has computed the attracting or lifting power of the earth at 42,310,000,000,000,000,000 tons. If this magnetism were equally distributed throughout the mass of the earth, the magnetic intensity of each cubic yard would be equal to about 60lb. attractive force.

TELEGRAPHIC FACILITIES IN GERMANY. — The German Postmaster-General has introduced another practical innovation, namely, that of allowing telegrams to be thrown into the letter-boxes, more especially those attached to mail cars on railway trains. It is only necessary to write out the message, mark it "telegram," and attach the tariff rate in postage stamps.

THE WHISTLING NUISANCE.—The General Manager of the London and Brighton Railway Company has introduced a system of electric communication between the platforms and the signal boxes at the Brighton Station, whereby the succession of loud locomotive whistles incidental to the starting of particular trains is entirely obviated. We hope to see the system extended.

NEW CATALOGUE.—Messrs. Weedon and Irish, electric engineers, of Sunderland, have just issued a catalogue of electrical appliances. It is well arranged, and contains an abundance of information, which will be found of considerable value to those in particular who are interested in the latest and most approved electrical inventions. There are numerous illustrations, and full price lists.

EARTHQUAKES AND EXPLOSIONS IN MINES.—Herr Rudolph Jall, the well-known geologist, who has made a special study of volcanic eruptions, publishes a caution to mine overseers. He says that explosions in mines usually coincide with, or follow close upon, earthquakes; and he mentions as days that will be dangerous in mines this year, all over Europe

Digitized by Google

March 30th, June 12th, July 12th, September 8th, and September 24th.

THE EASTERN TELEGRAPH COMPANY.—The Eastern Telegraph Company announce the payment on 14th April next of a dividend of 3s. per share on the preference shares of the company, less income tax, for the quarter ending 31st March, 1885; and that an interim dividend of 2s. 6d. per share on the ordinary shares of the company, free of income tax, in respect of profits for the quarter ended 31st December, 1884, will be paid on the same day.

THE ELECTRIC LIGHT IN AMERICA.—It is said that a new company, the American Electric Manufacturing Company, with a capital of £600,000, divided into 30,000 shares of £20 each, is about to be incorporated by charter taken out under the laws of the New York State. This company will absorb the business of the American Electric and Illuminating Company and that of the Boulton Carbon Company, together with other important electrical interests.

ELECTRICAL LEADS IN PHILADELPHIA.—At the close of the year there were on the highways of the city of Philadelphia 4,631 poles, exclusive of those along the lines of railroads; 4,499 miles of telegraph and telephone wires, 115 miles of electric light wires, and 341½ miles of underground wires. Belonging to the city there are 3,449 poles and 411 miles of telegraph wire, making a grand total of city and other overhead wires of 5,025 miles and 8,080 poles.

ANGLO-AMERICAN TELEGRAPH COMPANY.—The Board of Directors of the Anglo-American Telegraph Company have resolved (after placing the sum of £37,500 to the credit of the renewal fund) to declare an interim dividend for the quarter ending 31st March, 1885, of 4s. per cent. on the ordinary stock, and 8s. per cent. on the preferred stock, less income tax, payable on the 1st May to the stockholders registered on the books of the company on the 31st March, 1885.

A NOVEL INCANDESCENT LAMP.—A rather novel feature of one pattern of the Perkins incandescent lamp, which is now in use in some parts of America, is the arrangement of four carbon loops, which by means of a rotating switch can be made to give the light of one or more of these at the same time. The carbons are mounted in multiple arc within the globe This form is arranged for and used as a desk or table lamp, and the burning out of one of the carbons does not affect the remaining three.

THE ELECTRIC LIGHT IN GERMANY.—Judgment has been given in the action between Naglo Brothers and Eisenmann, proprietors of the Swan lamp, and the Edison Company, in favour of the latter. An injunction has been granted interdicting the construction and the sale of the Swan lamps in the German Empire. This decision, if it remains in force, will have a considerable effect upon the development of electric lighting in that country; and it certainly places the Edison Company in a very enviable position.

THE TELEPHONE IN SPAIN.—The telephonic service in Madrid has recently received considerable additions. At the date of the 1st of March there were already 80 places connected with the central station. It is said that the director of the Theatre Royal has decided to establish telephonic communication between the theatre and the houses of those who desire to partake of the pleasures of the opera. The subscription has been fixed at 500f. per annum. A hall will also be arranged for in the centre of the town where the public may hear the music.

SIXPENNY TELEGRAMS.—Down to the time of our going to press the Postmaster-General had not made his promised statement as to the Government proposals with regard to the new telegraph tariff, which is to come into operation in August next. But we understand that the decision arrived at is to charge for every word, addresses as well as text, at the rate of a halfpenny per word; or rather a penny for every two words, the charge progressing by pennies, not halfpennies. Thus, twelve words will cost sixpence, thirteen (or fourteen) sevenpence, and so on.

ELECTRIC TRAMWAYS IN AMERICA.—Our contemporary, the *Electrical World*, furnishes us with the agreeable intelligence that:—"One by one, street car companies in various parts of the country are adopting electric motors to replace horses. The Cleveland service is a success. A Daft plant has been furnished for a line in Baltimore, and we now hear that the Van Depoele Electric Manufacturing Company have sold an outfit for ten miles of street railway in Kansas City, Mo. The company are very sanguine about a rapid development of this part of their business."

THE ELECTRIC LIGHT ON BOARD THE "OCEANIEN."—The new packet boat of the company Messageries Maritimes has received an installation of 16 candle-power Edison incandescent lamps, which will light up the cabins, the saloons, and every other part of the interior of the vessel. For the decks, and for nightwork, lamps of 400 candle-power, and arcs of about 1,100 candle-power will be used. Messrs. Sautter and Lemonnier have furnished a steam motor of the system Wègy, which has a speed of 750 revolutions a minute. The two dynamos are of the Gramme system, with compound winding.

THE LIVERPOOL ELECTRIC SUPPLY COMPANY.—The directors of this company state in their annual report that the profits of the twelve months ended December 31, 1884, enable them to recommend a dividend at the rate of 5 per cent. per annum, after providing for all contingencies, and setting aside £150 for reserve fund. The dividend for the previous year (1883) was also 5 per cent. During the last few months the number of electric lamps supplied from the company's central station, in Elliot-street, has been very largely increased, the advantage of which will be felt in the augmented rental receipts of the current year.

THE CITY AND GUILDS OF LONDON INSTITUTE.—Examinations in technology will take place at the different provincial centres throughout the kingdom on Wednesday evening, May 20th, 1885, at seven o'clock. Individual candidates who are unable to arrange to be examined at a provincial science centre can, on application to the director and secretary, be examined in London at the Cowper-street Schools, E.C. The examination will be held in forty-seven subjects. A programme, containing syllabus of each subject and last year's examination questions, can be obtained from the office of the institute, Gresham College, London, E.C.

INFLUENCE OF MAGNETISATION ON THE CONDUCTIVITY OF MAGNETIC LIQUIDS.—Former experiments on the influence of magnetisation on the resistance of magnetic liquids have led to negative results. An account, however, has been given of an investigation on the effect produced by the magnetisation of ferrous sulphate as regards its electric conductivity. It would appear, so far as the experiments permit of a conclusion, that if the lines of the magnetic field are normal to the direction of the electric current, no effect is produced; but if the two are parallel to one another, the electric conductivity is increased, and eventually the E.M.F. of the polarisation of the liquid appears to be diminished.

Digitized by Google

ELECTRIC LIGHTING OF TRAINS.—The engines used for the electric lighting of trains on the Great Eastern Railway have continued running since October, 1884, with perfectly satisfactory results. The engine was coupled direct to its dynamo, specially made, the two being together on one bedplate. The whole was mounted on the top of the locomotive boiler behind the dome, so that it occupied no space on the footplate, and the steam could be taken direct from the dome. The regular speed was between 1,000 and 1,100 revolutions per minute. The light has never gone out once during the five months it has been employed. This is a great point in its favour, for it is most important that a light on an engine should not be extinguished, even for a few seconds.

THE ELECTRIC LIGHT IN PARIS.—It is said that the University of Paris has at last decided to introduce electric lighting in all its establishments. The Edison Company are about to lay down an installation of 550 incandescent lamps in the Lycèe Louis-le-Grand. The motive force will be furnished by two gas motors. As has been already announced, the incandescent light is in full operation at the Hippodrome. Besides the Serrin regulators and the Jablochkoff candles, which have been some years in existence, that immense building has received an addition of 800 Swan lamps, supplied by two Edison dynamos of 300 amperes and of 65 volts. These lamps have replaced the gas burners, and the effect produced is, it is scarcely necessary to observe, very satisfactory.

THE EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—This company to December 31st last show, subject to audit, a balance of profit of £110,126, after payment of three interim dividends and a bonus of 2s. per share for the first half year, and charging £42,767 against revenue during the year on account of cable renewals. The directors now propose to pay on the 30th proximo the usual dividend of 2s. 6d. per share, together with a bonus of 2s. per share, making, with previous distributions, a total payment of 7 per cent. for the year 1884.—This company announce the numbers of 433 Five per Cent. Debentures (1880 issue) of £100 each, which have been drawn for payment at par on 1st May at the Consolidated Bank, 52, Threadneedle-street, after which date interest on them will cease. The numbers will be found in our advertisement columns.

ELECTRIC LIGHTING AT LIVERSEDGE.—Messrs. Crooke, Son, and Co. have just completed an arc electric light installation in their large dyehouse with the most successful results. Jarman arc lamps of 2,000 standard candle-power each have been utilised, and give a very powerful and brilliant white light. Colour matching, we are informed, is done by means of this light equally as well as by daylight. The lamps are worked from a Jarman patent shunt-wound dynamo, giving a current of 10 amperes and 110 volts. The working parts of the lamps are completely protected from the vapours of the dyehouse by means of a specially constructed lamp case, and this prevents any of the metal parts from corroding or short-circuiting. Mr. W. B. Hutchinson, C.E., of Market-street, Heckmondwike, has directed the satisfactory carrying out of the installation.—*Gas and Water Review.*

ELECTRICAL TRAINING FOR SOLDIERS.—It is rather a remarkable fact that when it was proposed to organise an additional section of the 1st Division Telegraph Troop it became necessary to draw upon the postal service throughout the kingdom. It seems to have been more by luck than War Office judgment that the telegraphists lately sent out were ready to hand when required. The War Office, it is said, had nothing to do with their training, but the officers of a few regiments a little time ago sent a few intelligent men to the school in which the Post Office *employés* are trained, and thus some extra men were got ready. We have already advocated the establishment of a military school of telegraphy, not only for the Engineers, but for other branches of the service; and it is difficult to see how, if that service is to be an efficient one, the authorities can avoid the demand made upon them.

THE ELECTRIC LIGHT IN FRANCE.—A company recently organised in Paris will run a number of small steamboats (bateaux-mouches) on the Seine, thirty-two in number, which will be lighted by electricity. Each will have twenty-two incandescent lamps of 16 candle-power. The power will be furnished for each installation by a steam engine of 5½ horse-power. The dynamo is of the Gramme type (Rafford modification), running at a speed of 150 revolutions per minute, giving a current of 18 amperes at an E.M.F. of 110 volts. The dynamo also supplies current for the signal light, consisting of a powerful reflector, with one incandescent lamp before it. The firm of Breguet has undertaken the installations. Two French steamers, "Château Yquem" and "Château Margaux," which have recently been chartered to transport French troops to Tonquin, are also lighted by electricity. Each has about 200 lamps on board, put in by the same firm.

THE ELECTRIC LIGHT IN THE HOUSE OF COMMONS.—While the authorities of the House of Commons have deferred their final report upon the value of electricity as compared with gas for use in the lobbies of the House and within the Chamber itself, the reporters of the evening papers, who prepare their copy in the little ante-room at the back of the Reporters' Gallery, speak in terms of the highest praise regarding it. There are two small incandescent lamps with the usual switching arrangements, and each covered with a lacquered green shade which throws a diffused and agreeable light upon the small desk over which they are suspended. So good is the light that not a few gentlemen have expressed the desire that it might be extended to No. 18 Committee Room, which is used during the sitting of the House by the staffs of the morning papers, and which becomes insupportably hot in the summer months in consequence of the great heat given out by the large candle lamps now in vogue.

A NEW ELECTRICAL ENGRAVING MACHINE.—Lieutenant Buller Carter, R.N., of 27, Bow-lane, London, has invented an engraving machine, in which the delicate agency of electricity has been introduced into the mechanism with great success. It is intended for decorative engraving upon metal work. The letterpress or design to be engraved is first furnished by a setting of ornamental types or a stereotype plate. Over this is passed in parallel lines an arm of the machine, to which is attached a fine platinum point. The motion of the arm is responded to by that of the table, which carries the metal to be inscribed or decorated beneath the point of the engraver. The types or stereotype plate, by raising the platinum point, puts into circuit a current of electricity, which, acting upon an electro-magnet, raises or depresses the graver, and produces an enlarged or reduced engraved copy of the types, upon the metal on the table, with perfect accuracy, and at a trifling cost.

THE ALEXANDRA PALACE.—The present lessees of the Alexandra Palace have now a large staff of workmen engaged in making the necessary preparations for the opening on the 31st of this month. The grounds are being put in order, and spaces are being arranged for the numberless stall-keepers. Besides this there are some three or four hundred men engaged by the Gülcher Electric Light Company in fitting up apparatus both inside and outside the building. The Grove is to be lighted with electricity, and it is proposed to hold

Digitized by Google

concerts there throughout the season. The theatre, which has been rented by Messrs. Paget and Warne, will be lighted by electricity, as will also be the Oriental and English fairs, which the present proprietors regard as being the leading features of the show. An electric railway, which is to be run under the direction of Mr. Binko, is also regarded as another attraction. The New Bungalow Orchestra in the conservatory has also been fittedwith incandescent lights.

PROFESSOR WHEATSTONE AND LORD PALMERSTON.—The following anecdote, which we quote from the *Standard*, is fairly amusing:—"Lord Palmerston was one of the eminent men who had received his degree in the morning; and, standing at a little distance, I watched him as he listened to a somewhat prolonged exposition by Professor Wheatstone of certain new devices he had been busied with for the application of telegraphy. The man of science was slow, the man of the world seemed attentive; the man of science was copious, the man of the world let nothing escape him; the man of science unfolded the anticipated results—another and another, the man of the world listened with all his ears; and I was saying to myself, 'His patience is exemplary, but will it last for ever?' when I heard the issue:—'God bless my soul, you don't say so! I must get you to tell that to the Lord Chancellor.' And the man of the world took the man of science to another part of the room, hooked him on to Lord Westbury, and bounded away like a horse let loose in a pasture."

THE DELANY FAC-SIMILE TELEGRAPH.—This apparatus, to which we alluded in a previous issue as being adapted for the transmission of the Chinese language, has lately been practically applied to fac-simile transmission, whereby the hand writing of a correspondent, pen sketches, maps, plans, hieroglyphics, &c., can be sent over a single telegraph wire and reproduced at the receiving station with all their distinctive characteristics. Although other systems of fac-simile transmission have been tried, and fac-simile despatches have been sent and successfully reproduced, yet when but a single wire was employed, the time required for the transmission was so protracted, and the uncertainty of correct reproduction so great, that such systems of transmission could never come into actual commercial use. Mr. Delany's system, however, differs from all other systems of fac simile transmission in that it insures speed and certainty of correct reproduction. By means of the application of his synchronous system an area of twelve square inches can be covered in one minute by the use of a single wire.

THE WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY.—The Western Counties and South Wales Telephone Company has been formed to take over the rights and assets of the United Telephone Company in the following extensive district, comprising Cornwall, Devonshire, Somersetshire, Dorsetshire, the Channel Islands, Hampshire, the Isle of Wight, Wiltshire, Gloucestershire, Herefordshire, Monmouthshire, Glamorganshire, Carmarthenshire, Pembrokeshire, Cardiganshire, Brecknockshire, and Radnorshire, and all parts of Shropshire, Warwickshire, and Worcestershire as are not included within a twenty-mile radius from the General Post Offices at Birmingham and Wolverhampton respectively. The Post Office authorities have granted to the company a license which permits them to open exchanges at all places within this large and important district, and to connect the various cities and towns by trunk wires, and also—by agreement with the United Company and its subsidiary companies—to connect places in this district with those in any other district throughout the United Kingdom. They are also enabled to connect their exchange centres with the Post Office telegraphs, by which means subscribers may receive and forward their telegrams by telephone. Public call offices may be opened, wherein, upon payment of a small fee, the general public can communicate with any subscriber to the system.

LETTERS PATENT.—Our American namesake has an excellent article in its current number upon the defects of wording in patent specifications. Quite recently the Gold and Stock Telegraph Company applied for an injunction against the Commercial Company, alleging an infringement of one claim of the Colahan patent. This instrument is a type printer, with two parallel rotating wheels, one for printing letters of the alphabet, the other for printing numerals and fractions. "Each of these type wheels," says *The Electrician*, "advanced independently by a step-by-step motion communicated by an electro-magnet, ratchet, and pawl." The paper is forced upon the type by the action of a third electro-magnet. The claim alleged to be infringed is for "two or more type wheels, moving independently and controlled by magnetism, and arranged so as to print *jointly* or separately upon one slip of paper in two or more lines, substantially as specified." The weak point in the claim is the word we have italicised, the argument being that no one could tell what the patentee intended to claim from this wording—whether the apparatus claimed should print "jointly" or "separately," or both "jointly" or "separately," and so the injunction was refused. It has been our lot to examine many English specifications, and we fear if judges have to decide upon some patents, the wording will be found to attempt to include everything, and the patentee will find grasping everything means getting nothing.

NEW BOOKS.—We are in receipt of a comprehensive treatise upon "Electricity, and its Manner of Working in the Treatment of Disease," by Dr. W. E. Steavenson, to which is appended an inaugural medical dissertation on electricity for the degree of doctor of medicine in the University of Edinburgh, written in latin by Dr. Robert Steavenson in 1778, with a translation into English by the Rev. F. R. Steavenson, M.A. In the first portion of the work, which contains a variety of valuable information, we notice that in living nerve there is always a natural nerve current which can be detected by a galvanometer. The only change we are at present cognisant of as accompanying a nervous impulse is a negative variation of this natural nerve current. The rate of travelling of the negative variation along a nerve is 28 metres per second, and is identical with the rate of travelling of a nervous impulse. The negative variation passes in the form of a wave. The whole wave takes ·0007 of a second to pass any given point of a nerve. The length of the wave is 18 millimetres. Therefore a nervous impulse is a molecular disturbance propagated along the nerve in the form of a wave of the length of 18 millimetres, and possessing a velocity of 28 metres per second. Truly there are more things in Heaven and upon earth than are dreamt of in our philosophy. Were we not convinced of this fact we should hesitate to accept even the authority of Dr. Steavenson for the statement that "rubbing the soles of the feet a few times on the carpet will enable an inhabitant of the Southern States of America (query Canada?) to light the gas by the spark which will pass when he presents his finger to the metal point of a gas burner." However, whether that be open to discussion or not, the book is a very readable and a very interesting one, and is certainly a useful addition to our library.

THE DANGERS OF OVERHEAD WIRES.—A correspondent of the *Pall Mall Gazette*, on Monday last, writes as follows:—"For

Digitized by Google

many months six telegraph wires have hung over Wimpole-street, crossing it obliquely from Wigmore-street to Queen Anne-street, a distance of about 120 yards. Soon after eight o'clock last Sunday morning, owing to the weight of tenacious half-thawed snow, one of these wires fell with a crash into the empty street. Two policemen quietly removed the broken wire, and without your assistance probably nothing more will be heard of the accident. Had the wire fallen on a week day, when carriages and foot passengers are about, severe injury must have been inflicted upon man or beast." Other correspondents, on Tuesday, afforded similar evidence. "M. H.," writing from North Hill House, Dartmouth Park Hill, says:—"An accident similar to the one recorded by your correspondent occurred during the snowstorm of Sunday, on Dartmouth Park Hill, N. One of the telegraph wires suspended over this frequented thoroughfare fell directly across the garden in front of this house, breaking in its passage a large pane of glass, and extending across the road. Two passers-by coiled it up in the garden, where it still remains." Mr. H. E. Harper writes from Coleherne-road, South Kensington, as follows:—"A similar accident to that described by your correspondent occurred in Coleherne-road, South Kensington, on Sunday. A number of telegraph wires cross that road obliquely, and on Sunday morning last one of them, broken doubtless by the snow, lay along the road for some hundred yards, and then upwards towards the roofs of the houses, thus, to say nothing of the danger in the sudden snapping of the wire, causing a most dangerous impediment to any driver in the dark. After lying in the snow for some considerable time, the wire was picked up by a half-frozen policeman, who considerately coiled it in a confused mass round some newly-painted railings. On passing along the Strand this morning, at the corner of Bedford-street I noticed another broken wire dangling in mid air."

Electric Lighting for Steamships.—During the discussion upon Mr. A. Jamieson's paper, read before the Society of Telegraph-Engineers, upon the subject of Electric Lighting for Steamships, Mr. R. E. Crompton remarked that the question of low speed dynamos for ships had excited the greatest interest amongst the manufacturers of these machines, and great progress had been made. Up to a recent period, modification of dynamos for ships' use, as usually carried out, consisted in winding on to the armature an increased number of coils, making a large machine do the work of a small one. This was not a scientific mode of solving the problem. If, when put into the form of a simple formula, where $E_a = \frac{r\,n\,a\,\mu}{1{,}000{,}000}$, E_a being the electromotive force in the armature in volts, r the revolutions per minute, n the number of turns of winding on the armature, a the area of cross section of the armature core, and μ a coefficient which depended on the intensity of the magnetic field through which the turns of wire n passed; evidently, if the revolutions per minute were to be kept small, the requisite E_a would be obtained—1st. By making a large, and this involved a large and expensive machine.—2nd. By making n large, which meant winding a great number of turns of thin wire on the armature—3rd. By making μ large, in other words increasing the strength of the magnetic field. Whenever sea going engineers insisted on the revolutions of the dynamos being kept down to 500 revolutions per minute, so that the dynamos could be coupled direct to the steam engines which drove them, the first two methods only were employed. It remained for Dr. Hopkinson and for himself to obtain the necessary electromotive force at the required low speed, by increasing the strength of the magnetic field. This had been arrived at by using both for field magnets and for the armature core a greatly increased mass of the softest and purest charcoal iron, and proportioning the parts composing the magnetic circuit so as to obtain the least possible resistance to the passage of the lines of force. This enabled machines to be constructed giving sufficient electromotive force for working the lamps at the comparatively low speed of 400 revolutions per minute, and still to maintain a high efficiency or high proportion of useful output. By the older plan of increasing the turns on the armature, the efficiency of some of the machines used in the Royal Navy and elsewhere was only as much as 50 or 55 per cent. In the latter improved machines the efficiency was as high as 84 per cent. at the same number of revolutions.

The Inventions Exhibition. — Electric Lighting Arrangements.—The arrangements for the lighting of the buildings and the grounds are being proceeded with. Some 18,000 incandescent lamps will take the place of the coloured oil lamps for the illumination of the grounds and the roof of the large conservatory. Within the building there are to be 464 arc and 5,530 incandescent lamps, or more than double the number used last year. The Lighting Committee is composed of Sir Frederick Bramwell, the Marquis of Hamilton, Sir Frederick Abel, Mr. W. H. Preece, Professor Dewar, Colonel Sir Francis Bolton (who again undertakes the direction of the illumination of the fountains), and Colonel Festing. Twenty-one systems of electric lighting will be shown, equal to the illumination of 533,000 candles. The arrangement of the systems is—Eastern Arcade and Western Avenue, Varley lights by Goulard and Gibbs; dining rooms (on the site of the dairies), Bernstein lights by Paterson and Cooper; Chinese restaurant, Gulcher and Woodhouse and Rawson lights; Old London, Mackie lamps, arranged to produce a moonlight effect; Prince of Wales's Pavilion, Swan lamps; Water Pavilion, glow lights by Gooldon and Trotter; South Galleries Middle Court, Swan lamps, 1,080 in number, equalling 1,600 candles, by Mesers. Siemens; North Court, Victoria incandescent lamps, by the Anglo-American Brush Electric Light Corporation; South Court, lights by the Edison-Swan Company; Grill Room, lights by Clark and Chapman; Aquarium, glow lamps by the Gulcher Company; East Gallery, arc lights, by Thompson, Houston, and Co.; South Central Gallery, Jablochkoff arc lights; in different parts of the Exhibition, Pilsen lights, lamps by Paterson and Cooper; Cordner, Allen, and Co.; Clark, Muirhead, and Co. (Carden and Werner patterns); Sennett lamps, and lights by Clark and Bowman. There are also six Hochhausen lamps of 3,000 candle-power each, for the masthead; 12 Siemens lamps of the same strength for the fountains, and 16 Andrewes lights of 800 candle-power for the electric light shed. The steam-power which is to keep in motion the generators will again, as already announced by us, be provided by Messrs. Davey, Paxman, and Co., of Colchester. To the ten steam boilers and five powerful steam engines in use for the lighting of the Health Exhibition they will add eight large locomotive boilers. These new boilers, which are all made of steel of the first quality, are constructed with the most modern improvements. Each will contain 610 square feet of heating surface, and it is computed that, with easy firing, these eight boilers will evaporate 36,000lb. of water into steam per hour. With the whole set of eighteen boilers it is calculated that 110,000lb. of water per hour can be made into steam of 100lb. pressure per square inch. For the illumination of the grounds Messrs. Siemens will employ three engines, capable of about 1,000 horse-power work, by Messrs. Goodfellow and Matthews, of Manchester, supplied by Babcock and Wilcock boilers.

THEORY OF MAGNETO AND DYNAMO MACHINES.

XXVII.

It may be asked how it happens that this short-circuiting and reversing treatment applied to a coil conveying a powerful current is not attended with more vigorous sparks than are actually observed; but it is to be observed that both operations are of the nature of a *make*—at any rate, there is no true break of circuit. It is just the same operation as putting in and pulling out the plug P in the annexed diagram, except that, to be quite accurate, the battery connections should be supposed reversed every time.

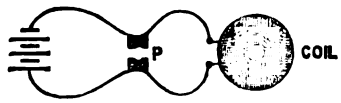

FIG. 1.

A better representation of the action can be given, much as Ayrton and Perry gave it in their article on electro-motors already referred to, viz., this

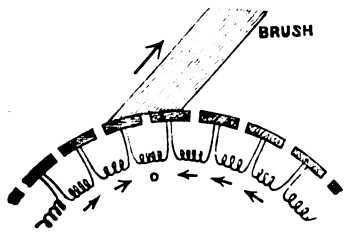

FIG. 2.

Commutator segments with brush resting on them. The coils connecting the segments are diagrammatically indicated, and the direction of the currents in them is shown by arrows. One of the coils is short-circuited by the brush, and the current will immediately be started in it in the reverse direction as the brush passes on.

where P is the brush contact (an Edison sort of brush it is) broad enough to more than bridge the gaps between the successive brass blocks of the commutator, and where the coils connecting the blocks are also very diagrammatically represented. Evidently as the brush moves on, it successively short-circuits each of the coils, and then reverses its current.

The preceding account of the action is in no way affected by the number of coils which the breadth of the brush contact enables it to short-circuit at once, for every coil still undergoes the operation, and undergoes it only once; but there is just this to be considered—viz., that the time of short-circuiting may be so short that the original current has no time to die out before reversal sets in, or it may be so long that the original current has time to die out completely; and in the latter case there is the further consideration as to whether, during the short-circuiting, any lines of force are being cut by the short-circuited coil or not.

The natural position for the short-circuiting to occur is in the line or plane of reversals; that is, where each coil is cutting no lines of force as it moves, or, in other words, where the total number of lines of force produced by the magnetisation of the armature as well as by that of the field magnet passing through the coil is a maximum. As far as external or impressed E.M.F. is concerned this is where the reversal of current should take place; and there it would take place if there were no internal or self-generated E.M.F. tending to prolong the current and delay its reversal. But there always is a self-generated E.M.F. or self-induction in any coil; it is greater if there is iron inside, but it is not *dependent* on the presence of iron by any means. Hence reversal of E.M.F. does not occur the instant a coil reaches the maximum line of force position, but it occurs at some angle ϕ in advance of this. This angle ϕ is what I have called the "lag." In this position some lines of force *are* being cut, but the impressed and self-generated E.M.F's are equal and opposite, consequently there is no current in the coil, except what may be driven through it by other coils.

Now, if there were no lag—that is, if ϕ were nothing—the brush might be set just in the maximum line of force position, the coils as they passed it would be cutting no lines of force, and the brush contact might be fairly broad. In the single coil machine there was an obvious advantage in paying attention to ϕ and setting the brush exactly at this angle in advance of the maximum line of force position, because then there was no current in the coil as the brush crossed the gap, and consequently no sparking or loss of energy, unless the brush were too broad and short-circuited the coil too long; and it ought not to be broad, for in the true ϕ position lines of force are being cut, proportional in fact to sin ϕ, and hence the short-circuiting angle ought to be infinitesimal. But in complex machines, where every coil has a current driven through it by its neighbours whether it is helping it itself or not, the advantage of paying exact attention to ϕ is not so manifest. The position of reversal is not one of zero E.M.F., as in a single coil, but of maximum E.M.F.; viz., just that position where the coil about to be short-circuited can contribute nothing to the E.M.F. Hence it might appear that the last dregs of help are obtained from every coil by setting the brushes at the angle ϕ in advance of the maximum line of force position; whereas, by neglecting this, some useful E.M.F. is wasted, and that this is the advantage of attending to ϕ. But then remember that the E.M.F. in a single coil after it has passed the maximum line of force position, *i.e.*, while turning through the angle ϕ, is entirely self-generated, and is due to the dying out of its own current. The diminishing current excites by self-induction an E.M.F. tending to prolong its life. Now, in a multiple coil machine the current in any one coil is not allowed to die out, but is kept fairly constant by the other coils; hence the self-induction has no opportunity of displaying itself, and as soon as a coil has passed its maximum line of force position it ceases to aid the current, and is best short-circuited out.

If this be correct, it follows that a fairly broad brush contact beginning at or near the true neutral plane is better than a narrow brush contact at an angle ϕ in advance; and much better than a broad brush contact at the latter place, because this would cause lines of force to be cut by short-circuited coils.

One advantage of a fairly broad contact is that it diminishes the resistance of the armature, not simply by increasing the area of contact, which a *wide* brush would equally well do, but by always short-circuiting out of the main circuit those few coils of the armature which at any instant are not helping the current on much, and whose resistance is therefore better got rid of. At the same time the number of such comparatively idle coils in a good machine ought to be very small. In a uniform field they would decidedly exist; but the object of curving the pole pieces well round the armature is to press every coil into active service as far as may be.

Besides the obvious gain in setting the middle of the brushes at the points of maximum and minimum potential respectively, there is also the advantage that the potential with which each segment of the commutator reaches a brush is the same as that with which it leaves it, and thus fluctuations of the current and sparks from this cause are avoided, as is fully pointed out in Article XX.

In a single coil machine each brush had to touch the middle of a commutator segment when the E.M.F. in the coil was a maximum, and it was to rest across the gap when the E.M.F. was zero. In the multiple coil machine the position of the brushes should be that of maximum E.M.F.

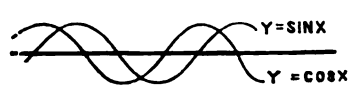

FIG. 3.

Of the two curves, each has its maximum where the other has its zero; illustrating the fact that at the position where the maximum E.M.F. can be tapped off an armature commutator, there each individual coil of the armature has no E.M.F. in it, and contributes nothing to the sum or total E.M.F.

always. The short-circuiting of each coil in the maximum position in the latter case, can be easily seen to agree exactly with the short-circuiting in the zero position in the [illegible] if

Digitized by Google

it be considered that the E.M.F. of all the separate coils in a multiple machine are added together, and that the result reaches a maximum just in the place where each coil adds nothing to the effect, *i.e.*, where it has zero E.M.F. in it. It is just the difference between the curves cos x and sin x, the latter being the integral of the former, and having its maximum when the other has its zero. See the formulæ in Article XX., where the E.M.F. of each separate coil was proportional to the *sine* of an angle: the total E.M.F. in all the coils was proportional to its *cosine*.

ALTERNATING CURRENTS.

BY THOMAS H. BLAKESLEY, M.A., M. INST. C.E.

(CONTINUED FROM PAGE 374.)

[*Erratum.*—P. 373, col. ii., lines 22-3-4 should be read:—$\frac{OE'}{r}$ and $\frac{E'F'}{r}$ are those currents considered as conveying electricity *into* the condenser, the positive current in R being of course a negative current as regards charging the condenser.]

We may easily extend the reasoning of the case when the circuit is bridged by one condenser to that in which at several points condensers are situated, as indicated by Fig. 8.

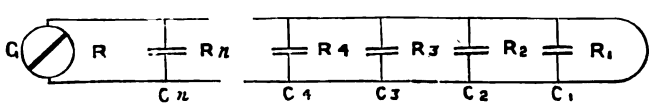

FIG. 8.

In this figure G is a generator, and the circuit is bridged at various points C_1 C_2, &c., by condensers of capacity C_1 C_2, &c. R_1 is the resistance of the remotest section, R_2 that of the section between condensers C_1 and C_2, R_3 that of the section between condensers C_2 and C_3, and so on, up to C_n, where the last condenser is situated. R is the resistance of that section which contains the generator. Suppose, also, that there is no self-induction in any of the sections.

So far as the two remotest sections are concerned, the distribution of flow will follow that of the case already given, when the potential difference of the plates of the condenser C_2 takes the place of the impressed E.M.F. Suppose, therefore, E_1 C (Fig. 9) to be the potential difference of the plates of

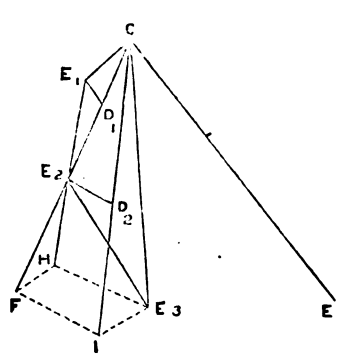

FIG. 9

condenser C_1, which for brevity we will call the E.M.F. of condenser C_1,

Set off the angle $E_1 C D_1$ in the direction of advancement so that its tangent is equal to $\frac{C_1 \pi R_1 R_2}{T(R_1+R_2)}$. Draw $E_1 D_1$ perpendicular to E' C, cutting C D_1 in D_1, and produce C D_1 to E_2, so that $C D_1 : D_1 E_2 :: R_1 : R_2$. Join $E_1 E_2$. Then E_2 C is the impressed E.M.F., so far as the two remotest sections are concerned. Therefore, E_2 C is the E M.F. of condenser C_2, and $\frac{E_2 E_1}{R_2}$ is the current in R_2.

Now, set off the angle $E_2 C D_2$ in the direction of advancement such that its tangent is equal to $\frac{C_2 \pi R_2 R_3}{T(R_2+R_3)}$, and draw $E_2 D_2$ perpendicular to C E_2. Produce C D_2 to L, so that $C D_2 : D_2 L :: R_2 : R_3$, and draw L F parallel to $D_2 E_2$ to cut C E_2 produced in F.

Produce $E_1 E_2$ to H, so that $E_1 E_2 : E_2 H :: R_2 : R_3$. Join F H, and draw H E_3 parallel to and equal to F L. Join C E_3, E_3, E_2. Then, E_3 C is the E.M.F. of condenser C_3, and $\frac{E_3 E_2}{R_3}$ is the current in R_3.

These points are proved by the following considerations:—

Firstly, $\frac{L F}{R_3}$ is the effective charging current for the condenser C_2, because $\frac{L F}{F C} = \tan F C L = \frac{C_2 \pi R_2 R_3}{T(R_2+R_3)}$ by construction, and $\frac{F C}{E_2 C} = \frac{\overline{R_2+R_3}}{R_2}$.

Therefore, $\frac{L F}{E_2 C} = \frac{C_2 \pi R_3}{T}$, or $\frac{L F}{R_3} \frac{T}{\pi} \frac{1}{C_2} = E_2 C$.

Therefore, by the formula given at the top of p. 327, col. ii., $\frac{L F}{R_3}$ is the effective current charging the condenser C_2, and L F being at right angles to C E_2, is in its right phase.

But E_3 H is equal and parallel to L F; therefore, $\frac{E_3 H}{R_3}$ is the effective charging current for the condenser C_2.

Secondly, one actual current affecting the condenser C_2 is $\frac{E_2 E_1}{R_2}$, which flows away from the condenser through the section R_2.

Considered as an accumulating current it is $\frac{E_1 E_2}{R_2}$; but $E_2 H : E_1 E_2 :: R_3 : R_2$. Therefore, $\frac{E_2 H}{R_3} = \frac{E_1 E_2}{R_2}$.

Thus $\frac{E_2 H}{R_3}$ is one of the currents composing the effective charging current $\frac{E_3 H}{R_3}$. Therefore, $\frac{E_3 E_2}{R_3}$ is the other component. That is to say, that $E_3 E_2$ is the effective E.M.F. in the circuit R_3.

This again being the resultant of the combined simultaneous action upon the resistance R_3 of the E.M. forces of the two condensers C_2 and C_3, and E_2 C being that of the condenser C_2, it follows that E_3 C is the E.M.F. of the condenser C_3.

It is clear that by extending the construction in the same way until we have taken all the sections into consideration, we shall ultimately arrive at one line, C E, which will represent the E.M.F. of the machine necessary to generate the currents indicated.

It would be very hard to construct a figure from the final line C E; but this process is unnecessary, because the actual value of the impressed E.M.F. would only affect the scale upon which the various lines should be measured, but not the angles or relative sizes of the lines in the diagram. A proper scale being therefore furnished from the final line to represent the value of the E.M.F. of the generator, it may be applied at once to the diagram to indicate—(1) the effective E.M.F. in each section as given by such lines as E_3 E_2, E_2 E E_1, which being divided by the resistance in the particular section will give the current—(2) the difference of potential of the plates of the various condensers as given by C E_2, C E_3, &c.

From the diagram it is clear that the general effect of condensers placed locally as bridges in a circuit is twofold. In the first place, when the sections of the circuit are considered in order, there is a continual delay in phase as we recede from the generator. In the second place, the current in the nearer sections is increased, and in the remoter sections diminished by the introduction of the condensers.

If in such a circuit there were a number of incandescent lamps in series, the effect of joining up with the condensers

Digitized by Google

would be that the lamps nearer the generator would shine more brightly, and those most remote would become duller, while there might be some in the intermediate sections which would indicate no change.

These observations serve to indicate the nature and reason of the delay in an alternating current in a long cable possessing capacity, which will be dealt with more minutely later on. They also explain the error in estimating an electric current by dividing the electromotive force by the resistance, when that electromotive force is a rapidly variable one, and there happens to be any great capacity for electricity involved in the system. It has been already indicated that a voltameter possesses capacity, and there is strong reason to believe that the tissues of the human body possess considerable capacity, probably in the same way as a voltameter possesses it.

If two Geissler tubes are placed in series in the secondary circuit of a Ruhmkorff apparatus, and the pole of a condenser is connected with their point of junction, then either tube may have the intensity of its light increased by the junction of the other pole of the condenser with that electrode of the secondary coil to which the other tube is attached. That other tube suffers a diminution or extinction of its light at the same time. It is in what has been called the remote section. A precisely similar effect is the result of using the two hands as the poles of the condenser. Of course this experiment lies open to the suggestion that it is the conductivity of the body which, when inserted in the system in the above manner, would relieve the remote section, and throw more current through the near one, that produces the effect observed. But there are numerous other facts pointing to the same conclusion, which can moreover be directly tested by suitable instruments.

(TO BE CONTINUED.)

MULTIPLE MAIN SYSTEMS.

BY W. H. SNELL, A.S.T.E. AND E.

A writer in an American scientific journal has recently developed some considerations relating to "multiple mains," from which he obtains "the most economical plan" of laying out any such system of conductors. But it is not very difficult to show that a still more economical plan is *possible*; and not only possible, but (so I venture to think) likely to be of some practical importance.

Let us compare a system of n conductors supplying a certain number of lamps with a system in which the same number of lamps is supplied by two conductors only.

In the latter case let C be the current, and let W be the economical weight per unit length for each conductor. Then, as an expression for the most economical current in terms of W, we can put

$$C = W\sqrt{\frac{k_2}{k_1}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

k_1 being a constant depending upon the cost of energy and k_2 a constant depending upon the annual charge for the cable.

Now, in a system of multiple mains (except towards the farthest extremity of any given branch) the current flowing anywhere in the intermediate wires, will be negligible in comparison with the current in the two external conductors. This is more especially true because we are concerned only with the heating effect of the current, which varies with its square. If, then, we neglect the heat wasted in the intermediate wires, we shall have, for the total cost of the energy expended in the mains, the expression

$$\frac{2C_n^2}{W_n}k_1$$

and for the annual charge upon the cables, we have

$$n\,W_n\,k_2$$

For the minimum value of W_n this gives

$$W_n = C_n\sqrt{\frac{2k_1}{n\,k_2}} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

But $C_n = \frac{C}{n-1}$, or inserting the value of C from (1)

$$C_n = \frac{W}{n-1}\sqrt{\frac{k_2}{k_1}}.$$

Therefore (2) becomes

$$W_n = \frac{W}{n-1}\sqrt{\frac{2}{n}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Up to this point we have substantially followed our American friend, and it is from a formula similar to the above that his "most economical" results are obtained. But if the current in the intermediate conductors at all approaches a negligible value, why need we make these wires of equal size with the outer pair? Of course the suggestion to use smaller intermediate wires is nothing new. If I remember rightly, such a proposal was originally made by Dr. Hopkinson, the inventor of the system; and Professor Forbes has recently expressed himself in favour of the plan—up to a certain point, of course.

But when this is combined with the other conditions of economy, such an arrangement possesses advantages which I think have not yet been mentioned.

Suppose that we make the weight per unit length of the intermediate conductors p times that of the external pair—p being some fraction. Then the expression for the annual charge upon the cables takes the form

$$W_n k_2 \{2 + p(n-2)\}$$

and therefore (3) becomes

$$W_n = \frac{W}{n-1}\sqrt{\left\{\frac{2}{2+p(n-2)}\right\}} \quad . \quad . \quad (4)$$

In the following table, which is derived from this formula, W_n indicates the weight per unit length for each of the external conductors, W_i the same for the intermediate conductors, and W_t is the total weight for n mains. Only three values of n are given; the higher values can hardly be considered to have any practical importance. Four values of p are taken; $p=1$, $p=0{\cdot}75$, $p=0{\cdot}5$, $p=0{\cdot}33$.

	n	p	W_n	W_i	W_t	Per cent of W_t
(1)	2	0	1·000	—	2·000	100
(2)	3	1·00	·408	·408	1·224	61·2
(3)	3	0·75	·425	·318	1·169	58·5
(4)	3	0·50	·447	·223	1·117	55·8
(5)	3	0·33	·462	·154	1·078	53·9
(6)	4	1·00	·236	·236	0·944	47·2
(7)	4	0·75	·251	·188	0·878	43·9
(8)	4	0·50	·272	·136	0·816	40·8
(9)	4	0·33	·288	·096	0·768	38·4

It will be seen that when p is less than unity we obtain a double advantage, for while the *total* weight is decreased, yet W_n, the weight of the working conductors, has been increased. So far this shows a saving over the results obtained from formula (3), varying from about 4½ per cent. up to nearly 19 per cent. upon the first cost, and "by construction" a *proportionate* saving in working expenses.

But this is not all. By thus diminishing the relative dimensions of the intermediate wires while maintaining the economical relation between current and resistance, at the same time we increase the limiting distance between any lamp and the nearest point of constant potential.

If L be this limiting distance in the case when $n=2$, then it may be shown that for any other value of n we shall have

$$L_n = L(n-1)\sqrt{\left\{\frac{2}{2+p(n-2)}\right\}} \quad . \quad . \quad . \quad (5)$$

or, when $p=1$

$$L_n = L(n-1)\sqrt{\frac{2}{n}} \quad . \quad . \quad . \quad . \quad . \quad (6)$$

From this formula (5) the results in the annexed table are obtained. They are numbered for comparison with the former table.

Digitized by Google

	n	p	L
(1)	2	0	1·00
(2)	3	1·00	1·62
(3)	3	0·75	1·70
(4)	3	0·50	1·79
(5)	3	0·33	1·85
(6)	4	1·00	2·12
(7)	4	0·75	2·26
(8)	4	0·50	2·45
(9)	4	0·33	2·60

No. 4 seems to be a very practical arrrangement; compared with No. 2 (where $p = 1$), it will be seen that we effect an economy of metal amounting to nearly 9 per cent, a certain economy of working expense, and at the same time the extreme distance which can be supplied from any one point of distribution is extended by about 10 per cent. Or compared with the double conductor system, we obtain an economy of about 44 per cent. in the weight of metal, and we increase the working distance by nearly 80 per cent.

The value of p ought perhaps to be determined by considerations as to the amount of current which the intermediate conductor might in an extreme case be called upon to transmit. But this should have reference solely to its capacity to convey such a current without overheating—the question of economy does not come in. Other things being equal, it appears to me that it is best to take p as small as possible in the larger mains, and to allow its value gradually to increase towards the extremities of each district.

THE INTERNATIONAL SOCIETY OF ELECTRICIANS.

(FROM OUR SPECIAL CORRESPONDENT.)

PARIS, March 25.

The Exhibition and Conference of the International Society of Electricians, now being held at the Observatory at Paris, was formally opened last Saturday. Special tickets were issued for the formal opening, and it was not till the next day that the ordinary tickets were of avail. It would be useless to attempt to lead any of our readers to expect that in the following description of this Exhibition he will find anything that is very new. Like all displays of its kind it has, however, caught the popular taste, and evening after evening the rooms devoted to the exhibition of apparatus are crowded with sight-seers. These rooms are more than well lighted by means of electricity, although in some cases the lights will not bear the test of careful examination, in that they have been—especially the arc lamps—rather hurriedly put up and flicker. It may be a token of supreme ignorance of all that concerns electrical societies when it is said that we have been unable to find the reasons which have led to this Exhibition. One friend was good enough to say that an analogy—only that it lasted but for one night—was to be found in the *conversazione* usually held once a year by the Society of Telegraph-Engineers. It is customary to exhibit a few instruments at such *conversazione*, and to in some way or other obtain a pleasant place of meeting. This *conversazione*, if it may be so called, extends over a week, and, in addition to the Exhibition, each evening there are one or two more or less popular lectures. From a scientific point of view we have nothing to say about these lectures, the visitors to the Exhibition crowd into the lecture room to overflowing, but it was conspicuously noticed that many whom it would have been thought would have been supporting the lecturer did not enter the lecture room. We fear that the life and work of the International Society, unless a considerable alteration takes place in its organisation, are destined to be short. What has an International Society of Electricians to do with a popular display? Such displays are mere advertisements, very good in their way—in fact, excellently so; but the work of such a society as this claims to be should be of a somewhat higher character than that we have described.

The steam-power used in driving the dynamos and the dynamos themselves are placed in a temporary building, which is to the right of the main entrance to the Observatory, and the leading wires of the various dynamos are carried to the points from whence the currents are taken. The dynamos are principally of the Siemens, Mcritens, Jablochkoff, and Gramme type. It was owing to the backward state of this machine room that the opening of the Exhibition was delayed for a week, and this delay, we believe, kept a good many English electricians from the Exhibition. The horse-power employed is obtained from six or seven steam engines, one of 60 horse-power, by Messrs. Chaligney and Co., which firm also supply a portable engine of 15 horse-power. The Société l'Eclairage Electrique has engines of 20 horse-power. Messrs. Triponé and Sons will have ready towards the end of the Exhibition a fast-speed engine, while Messrs. Weyher and Richemond have two engines respectively of 25 and 35 horse-power.

The yard inside the gates is lighted by means of Jablochkoff lamps, while from the summit of the Observatory are two projectors, and in various parts of the building are to be found arc lamps of the Siemens type and of the Cance, while the principal display of incandescent lamps is that of Gerard, who claims to exhibit a very economical lamp, of which more hereafter. Edison and Swan lamps are also exhibited in several rooms, and on the whole the incandescent lighting is very good, while, as we have said, the arc light is subject to annoying fluctuations. It is impossible to find anything new to say about the arc lights, or much that is new about the incandescent lights. With regard to the claim of the Gerard Company that their lamps are very economical, a 50-light lamp requiring 75 watts and being a low resistance lamp—that is, requiring E.M.F. of 30 volts, and taking a current of $2\frac{1}{2}$—there is still one fact wanting, namely, the life of the lamp. It will be seen that this claim is a candle per $1\frac{1}{2}$ watts, which after all is not a singular claim. The lamp shown by M. Aboilard, for example, gives, according to the exhibitor, a similar output.

Leaving for the present the electric lighting and coming to the ordinary exhibits, we notice that the only English house which can be said to be represented is that of Messrs. Elliot Bros.; their agent, Mr. Aylmer, exhibits a good selection of their instruments. The exhibit includes Thomson's galvanometers, condensers, resistance boxes, various ammeters and other of their well known instruments. Close to this exhibit is that of M. Menier, who is the only exhibitor of cables. Close by is the exhibit of Messrs. Maiche and Co., where will be found the micrometer for measuring very small resistances. This has already been alluded to in previous issues, and we intend to illustrate it. There is no doubt the instrument will be found very useful in many factories where the measurement of small resistances is a necessity. Another instrument which has attracted some attention is the modified Morse instrument of M. Estienne. The receiving position of this instrument prints the Morse symbols vertically instead of horizontally. Our readers will recollect that this has already been done in England by Mr. Herring. M. Estienne claims that his instrument is more simple than that of Mr. Herring, otherwise the advantages put forward for the use of such an instrument, such as the clearness of impression, the saving of the paper, and the impossibility of making any error between the dot and the dash are just those claims which are put forward by previous inventors. Messrs. Radiquet and Sons show a bichromate battery, for which they claim certain advantages. The porous jar forms on side of a W-shaped tube; when not in use this tube is thrown over by means of a hinge, and the liquid in the porous jar runs into the other arm, leaving the zinc out of contact with the liquid, and in throwing over the porous jar itself is also brought out of contact with the liquid in the other part of the cell. Thus, when not in use, the zinc is not in contact with the acidulated water, and the two liquids are isolated from each other.

(TO BE CONTINUED.)

PRIMERS OF ELECTRICITY.—These Primers (by Prof. Houston and others), which had a large sale at the recent Philadelphia Exhibition, can now be obtained at the office of *The Electrician*, price 1s. the set of twenty-seven.

LETTERS.

A letter awaits S. J.

OVERHEAD WIRES.—A NEW REMEDY.

It has often been a matter of surprise to us that the inhabitants of London have so long endured without active protest, though not without manifest impatience, the encroachments on private property, the violations of public decency, and the imperilling of public safety of which the telephone companies have been shamelessly and increasingly guilty during the past three or four years. That everybody's business is nobody's business seems peculiarly true of overhead telephone wires. At all events, whilst several parish authorities have been protesting in a half-hearted, disunited, and ineffectual way, it has been reserved for a private firm to take the first step which really promises some hope of an abatement of this crying evil.

According to the story told in the correspondence just published by Messrs. J. Travers and Sons, of 119, Cannon-street, London,—and we have no reason to suppose that their case is a peculiarly exceptional one,—the telephone companies have managed matters so that their own customers are beginning to revolt against the arbitrary and high-handed indignities to which they are subjected at the hands of the purveyors of public telephony. The firm just mentioned is not the first to have protested, but they appear to be the first to have gone the length of protesting with a purpose and determination to clear the company, their emissaries, and their fixtures off the premises, appealing to the public and to the Postmaster-General to come to the firm's assistance.

This is the interesting story as told by Messrs. Travers and Co. In March, 1880, they entered into an agreement with the United Telephone Company to supply the use of a telephone connected with their Exchange on the usual terms. Very soon the company discovered that the roof of Messrs. Travers' wholesale warehouse offered splendid facilities for erecting an almost unlimited number of additional poles, wires, and appliances; and that theirs was a convenient route for wires to take on the way to more distant regions. In spite of the continual complaints of Messrs. Travers, and the warnings of the ground landlords, the company's servants invaded the premises at their own sweet will, and erected a network of wires over the roof and glass skylight, sometimes doing actual damage, always jeopardising the safety of the customers below, and in the opinion of legal advisers were rapidly establishing a right of user which, if not resisted soon, might be difficult to upset.

The company took next to no notice of these complaints, but at length deemed it advisable, not for this case alone we may be sure, to alter the terms of their agreement with their customers as the old agreements fell through. Consequently in January last it was intimated to the refractory wholesale grocers and wine merchants of Cannon-street that a quite new form of agreement would have to be signed by them, or their use of the telephone would cease in the present month of March. The new agreement contained two clauses in particular which the Renter objected to. One clause requires him to give access to the company's agents, workmen, &c., at all times to the premises; and another clause covenants that the Renter shall give every facility "in the way of poles, attachments, &c., to the company for running his own wire"—a quite superfluous covenant we should think—but "*also those of other subscribers to the company's system whether exchange or private*"—a covenant which virtually compels a Renter not only to pay his subscription for the use of the telephone, but to provide free of cost and at his own risk wayleave and fixation for as many poles and wires as the company may please to establish on his premises. This, together with the right of way for the workmen "at all times," constitutes, we need hardly say, a virtual surrender of proprietorship, and, when the tenant is not the freeholder, as in the case of Messrs. Travers, a dangerous encroachment on the rights of the superior landlord.

On one occasion before matters came to this pass the renters, seeing the legal risks they were incurring, had threatened the company with legal proceedings if they did not remove all wires except the Renters' own. On this the company playfully retaliated by "severing our connection with the exchange"—we use Messrs. Travers' own words—"under pretence of altering our own wire, and kept us for three months without the use of our telephone, although we had paid you rent for that time, and there was no reason for not restoring the communication." Thus it would appear that when a customer shows signs of restiveness the company bring him to his senses, as grooms do rebellious horses, by reducing his provender. Failing this the brutes—we beg Messrs. Travers' pardon—are reduced by starvation. Trusting to these effectual methods the secretary of the United Telephone Company, Mr. Thomas Blaikie, wrote to 119, Cannon-street on January 29th, insidiously remarking, "We feel sure that on reflection you will see the reasonableness of the terms insisted on."

But here Mr. Blaikie's perceptions failed him. By that letter he not only lost Messrs. Travers as customers, but also the splendid roof and convenient resting place for a magnifi-

Digitized by Google

cent display of wirework in "a direct line between an Exchange and some of the most crowded parts of the City." Worse than this, the Postmaster-General is appealed to; and he has undertaken, if the rebellious grocers will find fifty subscribers, that an exchange system will be established by the Post Office at a rental something less than that which is paid to the United Telephone Company. As we gather from the terms of the Post Office Secretary's letter that the wires will be laid underground, it would appear that an underground system can be had by the public at the hands of the Post Office without any additional charge, and without any of the dangers and petty tyrannies of which the private company has been guilty, even though the guaranteed number of subscribers are to be counted by units when the company with its overhead system counts them by thousands.

This it seems to us is a conclusive answer to the oft-repeated assertion that the underground system is enormously costly. Some very misleading evidence on this point was tendered to the parliamentary committee on overhead wires at its sitting on Monday. It may be literally true that to erect a single wire overhead will cost thirty times less than to put it underground. But it is time this statement, which is only a partial truth, was explained away. Wire for wire the cost of the underground wires is not nearly so great, and the cost of laying them is mainly for the tubing; and when, as they always ought to be, they are submerged in large quantities, the comparative cost is reduced in proportion to the number of wires laid down. In other words, roughly speaking, while every additional wire erected overhead involves an equally additional expense, the cost of laying them underground is no greater for fifty wires than for one.

The object of Messrs. Travers in publishing this interesting correspondence is no doubt to obtain a sufficient number of subscribers to justify the Post Office in taking the matter into their own hands. We have always deprecated active competition between the Post Office and the companies; but we have always predicted that the time for it would sooner or later arrive, and we think this is the time for a Departmental interference. We hope that Messrs. Travers may succeed in their public appeal; but be this as it may we do not see how the Post Office can refuse to come to the rescue in a case like this. We agree that the Post Office, which derives a revenue from the granting of licences to these companies, "is the guardian of public rights" in this matter, and that in granting a special monopoly it is bound to see that the powers exercised under it are not abused to the injury of private property or the endangering of public safety.

CORRESPONDENCE.

THE BROOKS UNDERGROUND CIRCUIT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of February 21st, 1885, there is a description of the Brooks Underground Conduit, as exhibited at the late Electrical Exhibition in Philadelphia. So much of this notice as is copied from the examiners' report I desire to friendly criticise. "A number of experiments were made as to the effect of the Brooks system in reducing induction and other disturbing elements. One of these was a line through a Brooks conduit to the Broad-street station and a return through the earth." No wires whatever were worked to the Broad-street station. "A second circuit was metallic, *i.e.*, the message went and returned by wire, the distance between the station being about one and-a-quarter mile; the crackling noise was audible, but not loud or deep." We worked a metallic circuit to the Kensington station, seven miles, and also a single circuit the same distance, and endeavoured to show the difference between the metallic circuit and the single circuit. Remember the distance between the Exhibition and Kensington by the route of the wires is seven miles. "A line to Merion station and return by overhead wire, fourteen miles, worked nearly as well." As Merion station is only four and three-quarter miles distant, there is a very considerable error as regards distance, but a more serious error is the fact that there was nothing of the kind working to Merion station from the Exhibition. "No means were available for testing the amount of interference with each other of the several wires of telegraphic and telephonic circuits in the same tube, worked simultaneously." As the wires of the Pennsylvania R. R. Company for telephone and telegraph purposes, and three conductors of the Western Union Telegraph Company, operated by dynamos of high potential, were working it through the same tube during every hour of the Exhibition, all inductive disturbance came from those sources; and yet they say no means were afforded for observing the effect.—Yours, &c.,

H. C. FREMPT, Superintendent Brooks's Underground Conduit Company, Philadelphia.

THE TELEPHONE IN PARIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: *The Electrician* of the 24th January arrived this morning, and I beg to call your attention to the astonishing small number of physicians and lawyers who, as per your statements, are subscribers to the telephone in Paris, against the number of telephone subscribers of the same professions in Buenos Aires, namely:—Six physicians in Paris, against 113 in Buenos Aires; 21 barristers and solicitors in Paris, against 109 in Buenos Aires; notwithstanding the fact that the former town has nearly ten times the number of inhabitants of the latter.

The same number of *The Electrician* contains an article, headed "River Plate Telephone Company," which might convey the idea that the Gower-Bell is preferred here to the Bell-Blake, used by the United Telephone Company of the River Plate.

This is not the case. The number of telephones actually in use on the River Plate (in the Argentine and Uruguay Republics together) can be estimated to be as follows:—

Bell-Blake	3,210
Gower-Bell	2,120
Siemens	600
Breguet	250
Ader	130
Various systems	90
Total	6,400

As those numbers are changing daily, I could not guarantee their absolute correctness, but consider them to be a very fair estimate.—Yours, &c., AD. FELS, Director.

Buenos Aires, 26th February, 1885.

THE ELECTRIC TRAMWAY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I saw Mr. Holroyd Smith's system in action at Manchester. The arrangement for conveying the current to the tram certainly seemed very perfect; but in the case of continued heavy rain the water would be likely to partly or wholly fill up the channel the copper conductor slides in, reducing the resistance of the insulation considerably.

Would it not be better if this channel were in connection with the street drains at different parts of the route?—Yours, &c., W. S. H.

ORGAN-PLAYING BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should feel very much obliged if you or some of your readers would kindly give me a description of the devices for playing organs by electricity (command of stops, &c.), as frequently used in America for big instruments.—Yours, &c.,

FREDERICK DREXLER.

Vienna, IV. Mittersteig 17.

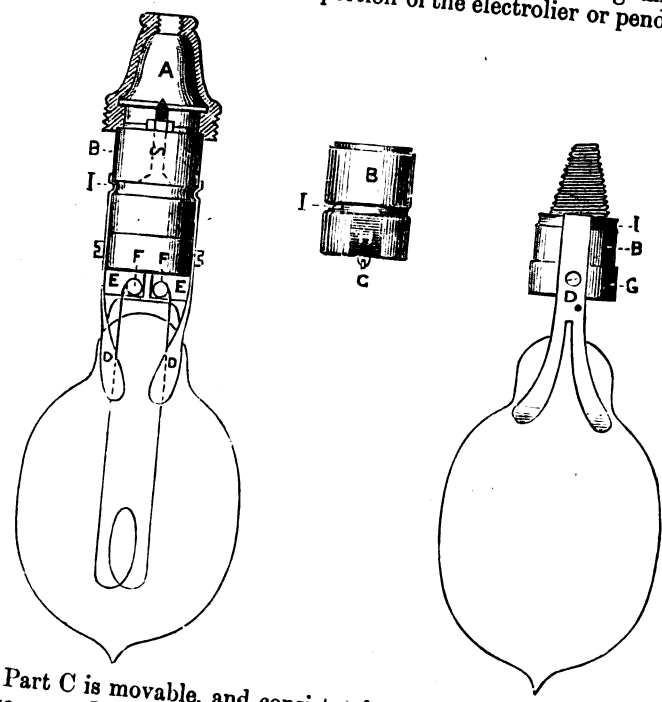
GRUNDY'S LAMP-HOLDER.

Fig. 1 is the lamp-holder as fitted at the Royal Courts of Justice. Fig. 3 is the same adapted to screw into an ordinary gas or other tube. Fig. 2 is the upper part of the holder, showing the electrical connections, which are identical in both cases. The insulating parts are different, inasmuch as the upper part of Fig. 1 is fixed to its socket by a screw through its centre, and has two holes for the leading wires, while Fig. 3 has to be screwed into the tube, and has only one hole through the centre for the two leads to prevent them being twisted in the operation.

A is the gun metal nozzle which is in use in the fittings at the Law Courts, for which these holders were originally designed. This nozzle terminates the pendant, tubular or flexible. If flexible the space of the tube is occupied by a plug of vulcanite or other insulator with two holes through it for the wires. The leads pass through two holes in part B, and are secured by the binding screws G in part B1, thus ensuring a good contact between the leads and the parts H, which extend up the sides of B as far af the groove I. S is the screw which secures B to A. The plates H, one on either side of B, now represent + and − of the circuit; and this part being unconnected is to remain a fixed portion of the electrolier or pendant.



Part C is movable, and consists of an insulating block, with two arms, D D, spread out in a fan-shape at one end, so as to partially encircle the neck of the lamp, and terminating at the other extemity in a shoulder made to fit the groove I in Part B. The lamp is connected by its legs to the arms D D by means of the split blocks E E being pinched between the two parts, then by the screws F F. A good contact is thus secured, as well as great rigidity in the lamp.

The parts of the arms D D which make contact with H H are about ½in. square, and the fact of their being so easily accessible, and their rubbing motion in switching off and on, ensures them being kept clean and bright.

As the lamp can at any leisure moment be fitted to the part C, and a few spare parts can be kept, the lamps can if necessary be replaced in a second, without any danger of fusing the lugs or lamp hooks, as is often the case in putting up a lamp with the current on. It is claimed for these holders that they are simpler and more reliable than any at present in the market. The construction of the holder and the security of its connections are such as to make it practically everlasting.

It can also be used as a switch whenever the lamp is within reach, and from the fact of both + and − being broken at the same moment no sparking is likely to take place. When required for this purpose a stop is provided to prevent overturning.

ON THE CHARACTERISTIC CURVES AND SURFACES OF INCANDESCENT LAMPS.*

BY J. A. FLEMING, M.A., D.SC. LOND., FELLOW OF ST. JOHN'S COLLEGE, CAMBRIDGE.

(CONCLUDED FROM PAGE 402.)

An attempt was made in the next place to endeavour to obtain an approximate empirical formula, connecting the efficiency of a lamp or the candles per horse-power and the electromotive force. On April 15, 1882, Professor A. Jamieson read a paper before the Society of Telegraphic Engineers and of Electricians (*Journal Soc. Tel. Eng.*, Vol. XI., p. 164), "On Tests of Incandescent Lamps," and he has there given a number of tables and curves for different lamps, giving the efficiencies and resistances for various electromotive forces.

These observations afford a convenient means of putting to the test empirical formulæ, because the observations seem to have been carried out with very great care, and being done with secondary and primary batteries as current generators. The observations are more likely to be accurate than when current from a dynamo machine is used; also because the observations for candle-power were entrusted to Dr. Wallace, gas analyst for Glasgow, and were therefore in the hands of an observer whose eye was probably more trained to detect minute differences of illumination than one not so familiar with such work.

Professor Jamieson gives one complete table of the constants of an Edison 8-candle lamp over a great range of candle-power. Selecting that portion of the table in which the electromotive force was high enough to illuminate the lamp, we have as follows:—

Tests of an Edison 8-candle Lamp, made by Professor Jamieson, March 8, 1882.

Resistance R.	E.M.F. in volts V.	Current in amperes A.	Candle-power K.
63·7	45·9	·722	5·2
63·3	46·7	·737	6·2
62·7	48·3	·77	8·2
61	51·9	·85	12·9
60·6	53	·874	14·3
59·3	56·2	·948	21·3
58·4	58	·995	25·3
57·8	61·1	1·06	35·8
57	63·1	1·21	43·8

If we take the logarithms of these numbers we have the following table:—

Edison 8-candle Lamp.

log R	log V	log A	log K
1·80414	1·66181	$\bar{1}$·85854	·71600
1·80140	1·66932	$\bar{1}$·86747	·79239
1·79729	1·68395	$\bar{1}$·88649	·91381
1·78533	1·71517	$\bar{1}$·92942	1·11059
1·78247	1·72428	$\bar{1}$·94151	1·15534
1·77305	1·74974	$\bar{1}$·97681	1·32838
1·76641	1·76343	$\bar{1}$·99782	1·40312
1·76193	1·78604	·02531	1·55388
1·75587	1·80003	·08279	1·64147

Let E be the watts of the lamp and R the efficiency or candles per horse-power. Then

$$R = \frac{K\,746}{A\,V},$$

and if we calculate the logarithms of the efficiency corresponding to each electromotive force value, and compare these with four times the value of the corresponding electromotive force, we have the following table:—

log *k*.	4 log *v*.	4 log *v* − log *k*.	
2·06839	6·64724	4·57885	
2·13834	6·67728	4·53894	
2·21611	6·73580	4·51969	
2·33879	6·86068	4·52189	
2·36229	6·89712	4·53483	mean = 4·52968
2·47457	6·99896	4·52439	= log 33860
2·51461	7·05372	4·53911	
2·61527	7·04416	4·52889	
2·63137	7·20012	4·56885	

Excepting the first and last values, which are the result of observations on the candle-power at extreme values, the intermediate figures are not very far from constant, and indicate, as a first rough approximation, that efficiency varies as the fourth power of the electromotive force.

At both high and low candle-powers the comparison of the light with a standard candle is difficult. In one case an excess of red, and in the other an excess of violet rays make the comparison of the naked lights much more difficult at extremes, and, as is well known, the efficiency for very high or low candle-power must be stated for a definite radiation. The only other comparison between these two variables attemped has been in the case of the experiments made by the committee appointed to report on the incandescent lamps in the Paris Electrical Exhibition, an abstract of which appears in the same volume of the *Journal* of the Society of Telegraph-Engineers. The committee condense

* Read at the Physical Society, 14th March, 1885.

Digitized by Google

these results on four varieties of lamps into the following numbers for the efficiencies, or candles per horse-power and electromotive force working them, taken at two very different values.

	Edison.		Swan.	
E.M.F.	89·11	98·39	47·3	54·21
Candles per horse-power	196·4	307·2	177·9	262·5
	Lane-Fox.		**Maxim.**	
E.M.F.	43·63	48·22	56·49	62·27
Candles per horse-power	173·6	276·9	151·3	239·4

If we take the logarithm of each number, and compare the difference of the logarithm of the efficiencies with the difference of the logarithm of the corresponding electromotive forces for each lamp, we have the following rates :—

Edison.	Swan.
$\frac{19428}{4302} = 4{\cdot}5$	$\frac{16895}{5922} = 2{\cdot}9$
Lane-Fox.	**Maxim.**
$\frac{20277}{4344} = 4{\cdot}6$	$\frac{19928}{4231} = 4{\cdot}7$

If, therefore, k_1 and k_2 be the efficiencies corresponding to two observed values v_1 and v_2 of electromotive force,

$$\frac{\log k_1 - \log k_2}{\log v_1 - \log v_2} = 4{\cdot}5,$$

or

$$k = C v^{4{\cdot}5}$$

represents an approximate formula for calculating the efficiency. If now approximately in the case of an Edison lamp the candles per horse-power vary, as the 4·5 power of the electromotive force, and the life varies inversely as the 25th power of the electromotive force, it follows that

$$l \propto \frac{1}{k^{5{\cdot}7}}$$

or, roughly that, the life varies inversely as some power between 5 and 6 of the candles per horse-power.

The writer was given in America an extensive series of observation on the relation between the candles per horse-power and the average life, which were as follows :—

Life.	Candles per H.-P.
11793	100
7150	110
4528	120
2974	130
2015	140
1403	150
1000	160
727	170
539	180
406	190
310	200
236	210
102	220

The length of life, 11793 hours, given as corresponding to an efficiency of 100 candles per horse-power, is nearly equal to four years of average burning in working hours, and could not have been the result of actual observation, but these numbers agree very closely with the law that

$$l \propto \frac{1}{k^{5{\cdot}25}}$$

where l represents life in hours and k candles per horse-power. It is most probable that this law has been deduced from observations on the life lying within an observed range and then extended by calculation to efficiencies below those actually observed. In any case these observations are not in great discord with the above deductions made from the numbers furnished by M. Foussat on the connection between life and electromotive force in conjunction with other observations on the relation of efficiency to working pressure in the case of Edison lamps.

It is, however, far more probable that the connection between the candles per horse-power and the working pressure is expressible by a formula of this kind

$$\log k = \alpha + \beta v + \gamma v^2 + \&c.,$$

where $\alpha\ \beta\ \gamma$ are known constants ; and in this case we should have then both the life-pressure, characteristic curve, and the efficiency-pressure characteristic curve expressed by analogous equations

$$\log l = a + b v + c v^2 + \&c.$$

$$\log k = \alpha + \beta v + \gamma v^2 + \&c.$$

We have seen above that such a formula does fit in with observed values for one pair of variables. Further examination of this point is desirable. Professors Ayrton and Perry have drawn attention* to a connection between the candle-power of a lamp and the working potential, and they find that in very many cases the cube root of the candle-power is proportional to the working potential minus a constant. Now, this is equivalent to saying that the candle-power of the lamp is proportional to the cube of the potential measured above a certain point.

* "On the Most Economical Potential Difference to Employ with Incandescent Lamps." *The Electrician*, March 7, 1885, p. 348.

I have examined some records of measurements of Edison lamps to put this law to further test, and the results are given below for two 16-candle Edison lamps measured by myself, and one 8-candle lamp measured by Professor Jamieson.

Edison 16-candle Lamp.—No. 1.

Candle-power = R.	Volts v	$\sqrt[3]{K}$	$v - 57{\cdot}17$	$\frac{v-57{\cdot}17}{\sqrt[3]{K}}$
16	105·27	2·5726	48·10	18·8
11·5	99·56	2·2572	42·39	18·8
8·25	94·32	2·0206	37·15	18·4
4·8	90·03	1·6869	32·86	19
2·8	85·74	1·4095	28·57	20
2	81·22	1·2599	24·05	19·08

Edison 16-candle Lamp.—No. 2.

R	v	$\sqrt[3]{K}$	$v - 50$	$\frac{v-50}{\sqrt[3]{K}}$
16	103·84	2·5198	53·84	21·5
13	100·03	2·3513	50	21·3
9·5	97·65	2·118	47·65	22·4
8·25	94·79	2·019	44·79	22·1
7	92·89	1·913	42·89	22·3
5·5	88·12	1·765	38·12	22·2

Edison 8-candle Lamp used by Professor Jamieson.

R	v	$v - 28{\cdot}7$	$\sqrt[3]{K}$	$\frac{v-28{\cdot}7}{\sqrt[3]{K}}$
5·2	45·9	17·2	1·7324	9·928
6·2	46·7	18	1·8371	9·798
8·2	48·3	19·6	2·0165	9·720
12·9	51·9	23·2	2·3453	9·892
14·3	53	24·3	2·446	9·937
21·3	56·2	27·5	2·772	9·921
25·3	58	29·3	2·936	9·981
35·8	61·1	32·4	3·296	9·831
43·8	63·1	34·4	3·525	9·759

In these cases we see that the cube root of the candle-power is very nearly proportional to the excess of the electromotive force above a certain point. Now, on examining a number of such cases it appears that this constant is the value of that electromotive force at which the lamp just begins to give signs of incandescence. In the case of the 8-candle lamp above, Professor Jamieson marks in his table against the E.M.F. 28·7 "filament bright red." It will be very interesting if further examination should give confirmation to this surmise ; but the above figures seem to indicate that the cube root of the candle-power is proportional to the electromotive force reckoned from the neighbourhood of that pressure at which the filament begins to give out light. If we call this excess pressure the "effective volts" then we can state the rule that the cube root of the candle-power is proportional to the effective volts. We have then, according to the observation of Professors Ayrton and Perry, in a certain number of cases an empirical law of this kind

$$\sqrt[3]{K} = a\,(v - b)$$

in which K is the candle-power measured at a pressure v–

This may be written

$$\tfrac{1}{3} \log K = \log a + \log (v - b)$$

By ordinary algebraic theory we have

$$\log a = \overline{a-1} - \tfrac{1}{2}\overline{a-1}^2 + \tfrac{1}{3}\overline{a-1}^3 - \&c.$$

$\therefore$ if $c = b + 1$ we can write $\log (v - b)$ as equal to the series

$$\overline{v-c} - \tfrac{1}{2}\overline{v-c}^2 + \tfrac{1}{3}\overline{v-c}^3 + \&c.$$

and

$$\log K = A + B\,\overline{v-c} + C\,\overline{v-c}^2 + D\overline{v-c}^3 + \&c.$$

If the supposition above made is correct that b is a value not far from that pressure at which the lamp becomes incandescent, then k is seen to be an exponential function of the effective volts of a kind similar to that which has been found to reconcile very well the values of observed life and corresponding working electromotive force.

Other observers have before now called attention to the fact, that within a certain range the candle-power of a lamp varies approximately as the sixth power of the current passing.*

In the case of the above-mentioned Edison 16-candle lamp, No. 1, the following values were obtained, connecting current and candle-power.

Candle power k	$\sqrt[6]{k}$	Current in amperes a	$\sqrt[6]{k} \div a$
16	1·5874	·7582	2·09
11·5	1·5024	·7065	2·12
8·25	1·4215	·6720	2·11
4·8	1·2988	·6203	2·09
2·8	1·1872	·5859	2·03
2	1·1225	·5514	2·02

The table shows that with considerable accuracy over a range from two

* At the British Association Meeting at Montreal, Mr. Preece read a note on this subject, confirming previous observations made in 1883, and showing, from observations of his own, Professor Kittler, and Captain Abney, that incandescence varies very nearly as sixth power of current.

Digitized by Google

to sixteen candles the incandescence varies as the sixth power of the current.

In those characteristics into which candle-power enters in any way there is a considerable difficulty in getting results with sufficient accuracy to determine the constants of the characteristic equations. There is, however, one pair of variables, namely, electromotive force and resistance, both of which can be measured with very high accuracy over a great range, and some very interesting examples of these pressure-resistance curves are given by Professor Jamieson in his memoir above alluded to.

A very short examination of the way in which an incandescent lamp behaves under increasing electromotive force shows that the resistance decreases with increase of electromotive force, but that it does not decrease without limit; it tends to a minimum value beyond which it appears to be constant. This is very strikingly shown for some of the Swan lamps tested by Professor Jamieson. In his paper certain formulæ are given connecting various lamp constants, and as a first approximation to a pressure-resistance equation is given the following :—

$$\log P = \log E + ar ;$$

when P is a constant E = E.M.F. and r = resistance.

It is not possible that such a formula should represent correctly the relation of resistance to pressure at high pressures, because it in no way expresses the fact that resistance tends to a minimum with increasing electromotive force.

An empirical formula can, however, be obtained, which will express this in the following way :—

Let R be the resistance of a lamp measured with any electromotive force, E, at the terminals. Let E_0 represent the electromotive force at which the lamp just becomes incandescent, and let R_0 the corresponding resistance. Let r be the minimum resistance to which the lamp approximates, as E increases until the filament breaks.

Then $$R = r + 10^{\log (R_0 - r) - A (E - E_0)}$$

is an expression which has the following properties :—

If $E = E_0$, then $R = R_0$,

if $E = \infty$ $R = r$.

The above formula is otherwise written

$$\log (R - r) = \log (R_0 - r) - A(E - E_0).$$

This formula has been tested for an Edison 8-candle lamp of which the resistance was measured over a considerable range by Professor Jamieson, and the resistance-pressure curve given in his paper. For this lamp luminosity commenced at 28·7 volts, and at this pressure it had a resistance of 73·4 ohms; its resistance gradually decreased with increasing pressure until it became apparently constant and equal to 53·5 ohms. Taking A equal to $\frac{1}{50}$ we have

$$50 \log (R - 53{\cdot}5) + (E - 28{\cdot}7) = 50 \log (73{\cdot}4 - 53{\cdot}5) = 64{\cdot}945.$$

Calculating R by this formula for various value of electromotive force E, we have the following table of observed and calculated resistances :—

Edison 8-candle Lamp.

E.M.F.	Resistance observed.	Resistance calculated by above formula.	E.M.F.	Resistance observed.	Resistance calculated by above formula.
28·7	73·4	73·4	48·3	62·7	61·57
32·7	71·1	70·05	51·9	61	60·34
36·1	68·1	67·65	53	60·6	60
39·7	66·4	65·49	56·2	59·3	59·13
43·1	64·7	63·78	58	58·4	58·66
45·9	63·7	62·51	61·1	57·8	57·98
46·7	63·3	62·19	63·1	57	57·58

The accordance between the observed and calculated resistances is fairly close. It seems very probable from an inspection of the values at very low electromotive forces that the resistance is a function of the electromotive force, reckoned from the pressure b, at which the lamp filament begins to be bright red, and that of R is the resistance corresponding to any electromotive force. E and r is the minimum resistance to which the lamp tends. Then

$$\log (R - r) = A + B (E - b) + C (E - b)^2 + \&c.,$$

when A B C, &c., are constants. If this should be the case, then it may be possible to express the life-candles per horse-power, candle-power, and resistance of a lamp, all as similar funcions of the electromotive force, knowing certain constants, and the two values of electromotive force at which the lamp becomes incandescent, and the resistance to which it finally tends to obtain. When, however, we are dealing with comparatively small variations of electromotive force, it is possible to calculate both life and efficiency from a simpler exponental function of the form—

$$l \propto v^x$$

$$R \propto v^y$$

when x and y are numerics. Assuming such an approximate formula, it becomes possible to deal with an interesting question, which has been discussed also by Professors Ayrton and Perry,* but which is capable of being investigated in a slightly different manner to that adopted by them in their paper. We shall take the warrant we have in the above figures for the assumption that for electromotive forces not far from those at which the lamp is intended to be used in the case of an Edison lamp, say 100 volts, that

Average life varies inversely as the twenty-fifth power of the electromotive force ;

Efficiency, or candles per horse-power, varies as the fourth power of the electromotive force ;

Candle light varies as the sixth power of the current, and therefore as the sixth power of the electromotive force, seeing that the resistance alters very little after the lamp has reached fair incandescence ;

And that therefore life varies inversely as the six and a quarter power of the efficiency, and also inversely as the four and a quarter power of the candle-power.

Let p be the price of a lamp in pounds, sterling, or fractions of a pound.

Let l be the average life in hours, c the actual candle-power, and k the candles per horse-power when run at a certain electromotive force v.

Then $\frac{p}{c\,l}$ is the cost of one candle light per hour as far as the lamp itself is concerned. Let P be the cost of 1 horse-power hour of electric energy expended in the filament. P will not be the same for all amounts, 1,000 p costs less than ten times 100 P, but for the small variations we are considering we shall consider P to be a constant. Then $\frac{P}{k}$ is the cost of the power in making one candle light for one hour, and the total cost of getting one candle light for one hour is $\frac{p}{a} + \frac{P}{k} = T$.

The first term is the expense of the translating device, and it may be called the cost of *lampage*.

The second term is the cost of the production of the energy which passes through the translating device or lamp filament and is converted into eye-affecting radiant energy, and this may be called the *machinage* ; hence the total expense of keeping going incandescent light is made up of lampage and machinage. Now, we can procure a given amount of light either by running the lamps very high, in which case lamps will cost a great deal, and power less in proportion, or we can run the lamps very low and save in lampage, whilst expending more in power in a greater number of lamps ; and the question arises, apart from capital expenditure, at what point is the greatest economy obtained, or, in other words, what proportion ought lampage to bear to machinage in order that the total cost may be a minimum? To solve this we shall assume, as is very probable, that for the limit of variation of E.M.F. employed, the average life of the lamp is an exponential function either of the candles per horse-power k, or of the candle light c, for the particular lamps considered.

Let $l = \frac{1}{k^{\alpha}}$

and $l = \frac{1}{c^{\beta}}$ be the functions,

α and β have definite values at a given E.M.F.

Then $$c\,l = l^{1-\beta} \qquad k = l^{-\frac{1}{\alpha}}$$

Substituting, we have $$\frac{1}{k} = l^{\frac{1}{\alpha}}$$

or $$p\,l^{\frac{1}{\beta}-1} + P\,l^{+\frac{1}{\alpha}} = T.$$

Now this expresses the total cost of working as a function of the average life at a certain E.M.F.

Let us also take that $l = \frac{1}{v^{\gamma}}$ where v is the E.M.F. at which the lamps are being run.

Then $$p\left(\frac{1}{v^{\gamma}}\right)^{\frac{1-\beta}{\beta}} + p\left(\frac{1}{v^{\gamma}}\right)^{\frac{1}{\alpha}} = T$$

or $$p\,v^{-\frac{1-\beta}{\beta}\gamma} + P\,v^{-\frac{\gamma}{\alpha}} = T$$

Let this be varied by varying v; to find at which value it becomes a minimum with respect to v, differentiate with respect to v, and equate to zero.

$$\frac{dT}{dv} = 0 = -\frac{\frac{1-\beta}{\beta}\gamma\,p\,v^{-\frac{1-\beta}{\beta}\gamma}}{v} - \frac{\frac{\gamma}{\alpha}\,P\,v^{-\frac{\gamma}{\alpha}}}{v}$$

or $$-\alpha\frac{1-\beta}{\beta}\,p\,v^{-\frac{1-\beta}{\beta}\gamma} = P\,v^{-\frac{\gamma}{\alpha}}$$

Hence, the total cost of working is a minimum when the cost of power, $P\,v^{\frac{\gamma}{\alpha}}$ is to the lampage $p\,v^{-\frac{1-\beta}{\beta}\gamma}$ as $\alpha\frac{1+\beta}{\beta}$ to unity.

* "On Potential Difference, &c."

Digitized by Google

Now the above investigations show that for Edison lamps α is a quantity in the neighbourhood of $6\frac{1}{4}$ and β near $4\frac{1}{2}$,

hence $$-\alpha\frac{1-\beta}{\beta}=\frac{19}{4},$$

and hence ratio of lampage to total cost is $\frac{4}{23}=17{\cdot}4\%$.

Hence we arrive at this curious result, that independently of the price of lamp or electrical energy we must run at such a pressure that lampage is about 18 % of the total cost. Now, if instead of employing these approximate exponential expressions for the values of l, c, and k in terms of the electromotive force we had introduced the more accurate forms of equation indicated above, we should have had an equation in terms of v to solve as the result of equating the differential to zero, which would, by the introduction of the proper constants, give the value of electromotive force at which the total cost becomes a minimum. In their paper Professors Ayrton and Perry have calculated to a fraction of a volt what this economical potential is. As, however, the characteristic equations are only approximate, it seems hardly necessary to do more than obtain a similar approximate expression for the economical working.

At the Edison lamp factory in America calculations were made on the assumption of a particular type of lamp, and length of life, and cost of power to ascertain the ratio of lampage to total cost, which made the total cost a minimum, and the result appeared to be to fix it at about 16 per cent. These observations are therefore in singular accord with the deduction of theory based on determination of the constants of the characteristic curves, and are arrived at both by graphic and analytical methods.

ON THE SEAT OF THE ELECTROMOTIVE FORCES IN THE VOLTAIC CELL.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

(CONTINUED FROM PAGE 378.)

It may be readily objected that what the soaking with gas accomplished was not the formation of a film of gas, but a film of actual chloride, oxide, or other combination. Against this is to be urged the fact that after removal from the gas the effect diminished with time, and the plates gradually returned to nearly their former state. He tried if he could remove the gas film from one of the plates by exhaustion under an air-pump, and the plate so treated exhibited a difference when taken out and compared with an ordinary plate; but he was cautious enough to repeat the experiment, leaving the plate under the bell-jar for the same time and not exhausting. The same difference appeared, so he attributes it to possible grease.

This is the right sort of way to make experiments; and if everybody experimented with proper care there would be vastly fewer papers published, and science would progress on the whole faster.

At present it feels to me overladen with a mass of publication, mostly of necessity by men of not absolutely the first order, much of it with no sort of clearness or insight, but rough, crude, and ill-digested. A man makes a number of experiments; he does not stop to critically examine and weigh them, and deduce from their meaning, nor indeed does he often take the trouble to examine whether any definite meaning can in their then shape be drawn from them; but he rushes with them into print, producing a memoir of wearisome length and sometimes extreme illiterateness of style.

Some one else then has the trouble of wading through the heap to see whether any fragments of value may perchance be imbedded in it, and probably he is unable to come to much definite conclusion, because he cannot be in so good a position for criticism of the experiments as the original author was. He therefore writes a paper pointing out defects and errors in the communication. Others take up the same line, the original man replies, and so there is a controversy, and nothing is really settled at all. Finally, some one else independently goes over the whole ground from some distinct point of view, makes a few well-planned, clear, and decisive experiments, describes them in a compact and readable form, and there results a definite gain to science. But how much better would it have have been if this last paper had been the only one published! Unless a man is an experimental genius of the highest order, it is necessary for him to think for far more time than he experiments, if he wishes to advance and not to lumber his science. If it be objected, as indeed it may with great truth be, that one man's life and capacity are not sufficient for this in the present state of knowledge, the objection constitutes a strong argument in favour of the proposition that the time has come for an organisation of science and a more definite division of labour.

To return to the experiments of Herr Schulze-Berge, one is not able to say after all that they are very satisfactory, for they do not distinctly settle any question. The general conclusion he draws from them is the apparently safe one that the contact-force between a metal and a gas is not in general the same as betweeen a metal and air. Even this is not absolutely safe, however, because it might conceivably be that an air/gas contact-force caused all the difference. Granting that this is unlikely, the experiments are in favour of a contact-force between metals and air or gas; but they do not establish the fact any more strongly than, if so strongly as, Mr. Brown's experiments had already done. The weak point in both is the possible corrosion of the plates and formation of films of alloys or compounds, which may be the real source of the observed difference of potential.

* Reprinted from the *Phil. Mag.* for March.

And against the existence of a contact-force between metals and various gases, the experiments of Pellat and others are to be remembered, which resulted in the conclusion that a condenser made of two different metals showed nearly the same Volta effect whether the atmosphere surrounding the plates was air or hydrogen.

If it be assumed that the experiments of Brown and Schulze-Berge establish their point, and that Pellat's apparatus for different gases (Fig. 9) is satisfactory (rather a large assumption), I am unable to reconcile the discrepancy, except by suggesting that Pellat did not take sufficient pains to remove the condensed-air sheet originally on both his plates. It is of course just possible that the *difference* between the potentials of the two metals might be the same in two gases though the absolute potential of both was different, but it is improbable.

In this connection I must notice also a rather long memoir* by Dr. W. von Zahn, published in 1882, which reviews the whole subject, and describes an elaborate series of measurements made with an apparatus something like what one might suppose Ayrton and Perry's to become if it were arranged for use in different gases and *in vacuo*. He refers with admiration to Pellat's work in the preface; and I do not suppose imagines that his own numerical determinations can compare with Pellat's for accuracy where they overlap, seeing that he only makes use of a sort of combination of Kohlrausch's and Hankel's methods, with a Hankel electrometer as a measuring instrument.† He has tried, however, a large number of substances as well as ordinary metals, such as powdered antimony, iron and nickel reduced by hydrogen, many kinds of carbon, Fe_3O_4, manganite, pyrolusite, copper oxide, lead "hyperoxide," iron glance, and other minerals. He has measured the Volta effect in various gases and at different pressures, and finds, like Pellat, that it does not appreciably vary.

He has also examined the effect of temperature on the Volta effect, though he appears to think that this ought to bear some close relation to the phenomenon of Seebeck, a natural mistake many years ago when made by Avenarius, whom it led most happily, though fortuitously, to the true, and by him experimentally verified, law of E.M.F. in a thermoelectric circuit.‡ However, Zahn finds that experiment lends no support to this view, and says that a larger series of results must be obtained before basing a theory on them. Von Zahn is a confirmed contact theorist, and he victoriously assails several experiments supposed to be distinctly in favour of a chemical view of the Volta effect. He says he publishes his results because of the extraordinary discoveries being propounded by Professor Exner (such as that a thermopile will not work in a vacuum)§, and because of the vague and unsatisfactory views of physicists in general on the matter (*e.g.* of Hart); but I am bound to say that, so far as I can judge, Dr. von Zahn's own experiments are not of that conclusive and decided character that one had hoped for from his start, and he signally fails to sum up the facts in a neat and crisp manner. He adheres to the contact view, but his adhesion scarcely seems to me to be based on strong evidence; and in fact his theoretical views seem a little superficial considering the date at which he writes; so that one may admit pretty well all he says about contact and not chemical action as the cause of the Volta effect without being deeply committed to any specially true or specially false position.‖ His best experiment, and a very crucial one if only it could be perfectly performed, is the attempt to measure the Volta effect in an absolute vacuum. A pair of zinc and platinum plates are sealed up in a brass and glass vessel in such a way that one of them is capable of moving up and down, and thus of varying its distance from the other. Gravity is employed to separate the plates, the whole vessel being inverted. The vessel is filled with dry nitrogen and exhausted for some days, occasional heat, P_2O_5, and melted sodium, being employed to improve the vacuum.

The result is that the Volta effect is very decidedly "too small," going down to half a Daniell, so far as the measurements made by his not

* *Untersuchungen über Contactelektricität*, von Dr. W. v. Zahn: Leipzig, Teubner, 1882.

† A Hankel electrometer is a modification of Bohnenberger's, in which a battery with middle to earth is substituted for the dry pile; the plates on either side of the gold leaf are minutely adjustable, and the motions of the gold leaf are read by a microscope. It is sometimes preferred to a quadrant for its small capacity and dead quick motion; it can be made very sensitive, but it can hardly be a satisfactory measuring instrument. Pellat used it, but only as an electroscope.

‡ Avenarius, "Die Thermoelektricität, ihrem Ursprunge nach, als identisch mit der Contactelektricität betrachtet," Pogg. *Ann.* cxix., 1863. See also Pogg. *Ann.* cxxii., where he proceeds to calculate Volta effects from thermoelectric data.

§ I have been unable to find this extraordinary statement in Exner's works, but it is quoted again by Ayrton and Perry, Phil. Mag., 1881, p. 49. Exner seems to have said that the thermoelectric power of bismuth-antimony is destroyed by immersing the pile in pure nitrogen; and Young of Princetown takes the trouble to examine whether it is so experimentally (see *Phil. Mag.* x. 1880, p. 450), and finds the thermoelectric power of metals the same at one millionth atmosphere as at 1. This, however, would be altogether inconclusive if experiment were needed to settle it.

‖ I am afraid this is not peculiar to Dr. von Zahn. It may be that the German writers on the subject are too busy accumulating facts to care much about their precise theoretical bearing; but I notice a very loose and unsatisfactory way of putting forward secondary matters as if they were the real points at issue, and of never really getting to the heart of the matter. It is singular that the four questions or heads under which that eminent writer, Professor Wiedemann, proceeds to discuss the attempts which have been made to settle the question of the seat of E.M.F. are such that if a categorical answer to each were, by supernatural means, vouchsafed to us, we should be, I believe, none the wiser (Wiedemann, *Elek.*, vol. ii, p. 985, new edition).

Digitized by Google

entirely unobjectionable method can be trusted ; but he does not seem to think that this is much of an argument either way, and, not finding any further change after some days, he did not pursue the investigation further by letting in some air and seeing whether the old value is restored, though he perceives clearly that this would be a crucial experiment. This abstinence is so remarkable that it seems necessary to quote his own grounds for it, and I do so in a footnote.*

Zahn goes on to describe an experiment with bright sodium *in vacuo* instead of zinc, the sodium having been long kept melted in a laterally connected bulb before being introduced into position. He finds the sodium strongly positive to copper ; but there can be nothing crucial about this experiment, I imagine, for metal in contact with glass may so easily give rise to disturbing electrifications.

I believe he must have employed the best vacuum of any experimenter on this subject, and that he has therefore gone most near to the proof of what I cannot help believing will be found to be the truth, viz., that the Volta effect in an absolute vacuum or perfectly inert gas (old air-sheets *et hoc genus omne* having been thoroughly removed) is very small. But if it be the case, as I believe it is, that the effect is almost independent of the *quantity* of oxygen present, so long as it is present, the difficulty of making the experiment so as to be sure of the absence of even the last few thousand or million oxygen molecules is almost overwhelming. The question of the dependence of Volta force on atmosphere remains thus undecided ; and all the evidence which I can adduce in favour of such dependence is this incipient decrease observed by von Zahn, the little too-mixed-up observation of Mr. Hart (described later), the measurements of Schulze-Berge, and the more decided experiments of Brown. It may, indeed, be readily held that the weight of experimental evidence tends the other way, since most experimenters on the subject (Pellat, Schulze-Berge, von Zahn, and I may add Sir W. Thomson) have left off just as pure contact theorists as they began. I would attempt an experiment myself, save that I am so profoundly impressed with the difficulty of making one in which no fault or loophole can be found, and which will by every one be deemed satisfactory and final ; so I prefer to base my views on a general survey and on fairly conclusive reasoning, rather than on a crucial but almost impossible experiment.

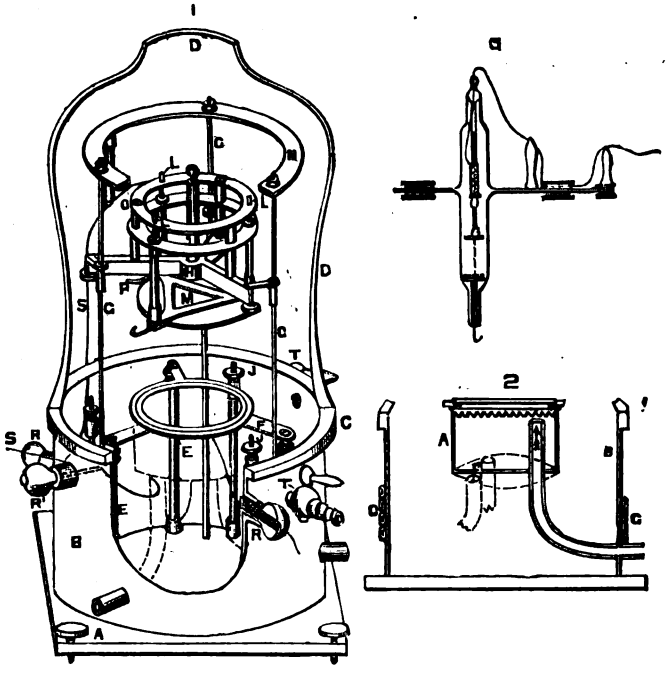


FIG. 11.—Von Zahn's Apparatus for experimenting in different Gases at different Pressures and Temperatures, and also in high Vacua.

The upper plate, M, is attached by glass rods to a sledge, H, which slides on vertical steel rods, G, being pulled up by a string. On reaching its highest point it comes into contact with an insulated platinum wire, S, which communicates with a Hankel electrometer through one of the insulated exits, R. The bottom plate is supported on the ring, E. T is the stopcock for exhaustion and change of gas. Fig. 2 shows the appendage to the bottom plate for warming it by a current of steam. Fig. 3 shows the apparatus used for high vacua. The two plates are zinc and platinum, and the platinum is arranged to fall by its own weight when the whole thing is inverted. The diagram shows it in its highest position, and just going to fall back into its dotted position. The friction of its guide-rod seems not wholly satisfactory.

5. Perhaps this is now the place to refer to the somewhat erratic series of papers by Professor Franz Exner, of Vienna*. He sets himself to disprove the existence of contact force in the most straightforward and obvious manner, and to establish the fact that there is no electrical evolution without definite and actual chemical action. To this end he announces the following propositions :—(1) that two metals in a chemically indifferent medium show no electricity ; (2) that the potential difference of two connected metals in air is exactly half the difference of their heat-combustion energies ; and (3) that two pieces of the same metal produce contact-electricity as soon as they are put into chemically different atmospheres.

The experiments by which he supports these assertions have, every one of them, been elaborately and severely criticised by Beetz, Horweg, Julius, Schulze-Berge, Von Zahn, Ayrton and Perry, Pellat, and Wiedemann ; and his numerical determinations of contact-force appear to be unique†.

It is not necessary for me to enter into a discussion on the merit of his experiments, inasmuch as the mere fact of the existence of so great a body of hostile opinion is sufficient to show that they are not of a kind best qualified to produce conviction. The theoretical views which led Professor Exner to formulate his second statement above, that the potential-difference of two connected metals is equal to half the difference of their heats of combustion per equivalent, are, I am sorry to say, quite unintelligible to me. They depend on the hypothetically necessary existence of films of oxide, between which and the metal there is supposed to be a considerable difference of potential. Perhaps a few quotations from Professor Exner's first paper on contact-electricity will render his position clearer‡. His views are but little really different from those of De la Rive and other older "chemical theo-

* "Andere etwas bessere Beobachtungsreihen gaben ähnliche Werthe. Bei allen war die Kleinheit von C. (the apparent Volta effect Zn/Pt) auffallend. Nun stellt ja dieser Werth, wie oben besprochen, nicht die Potentialdifferenz Zink-Platin dar, für seine Kleinheit muss aber eine anderweite Ursache vorliegen. Dieselbe kann ich zunächst nur darin finden, dass die Zinkplatte bei Anfertigung und weiterer Behandlung des Apparates sichtbar angelaufen ist (auf der einen Hälfte sogar blaue Färbung angenommen hat).

"Es liesse sich allerdings vermuthen, dass diese offenbar zu geringe Differenz in der wirklich wesentlichen Verminderung von Feuchtigkeit und Sauerstoff gesucht werden müsste, so dass der Apparat nach dem Oeffnen eine stärkere Spannung zeigen würde. Dies wäre dann wirklich ein *experimentum crucis* zu Gunsten der chemischen Theorie. Diese Entscheidung vorzunehmen wird aber erst dann nothwendig sein, wenn nach längerer Zeit, wo das eingeschmolzene Natrium noch mehr alle Reste von Sauerstoff beseitigt haben wird, eventuell noch Wiederhitzen und dergl. der jetzige Zustand des Apparates unverändert wieder gefunden sein wird."—*Von Zahn's Memoir*, p. 48.

‡ I quote from Mr. J. Brown's translation (*Phil. Mag.*, Oct., 1880) of a paper in Wiedemann's *Annalen* of the same year, with some abbreviations :—"An investigation concerning the nature of galvanic polarisation has led me to a quite distinct view of the origin of the so-called contact-electricity, a view which will be supported by experiments following. I have shown that the original cause of the polarisation-current is to be sought for, not at the contact of the electrodes with ions liberated on them, but in the recombination of the latter ; and the E.M.F. of the current so produced is measured by the heat-value of this combination, just as the E.M.F. of any galvanic cell is measured by the heat-value of the chemical process going on in it. With a so-called contact-action the existence of the polarisation-current, and obviously of every other current, has nothing whatever to do. The idea then suggested itself to seek for the cause of the production of electricity in the experiment of Volta, not in the contact of two metals, but in previous chemical actions of the surrounding media on their surfaces. I have expressed the opinion that so-called contact-electricity is produced by the oxidation of the metal in contact by the oxygen of the air, just as in galvanic cells it is evolved by oxidation of zinc. If the supposition prove true, and it has proved true, the E.M.F. of his metal in contact in air must be measured and expressed by their heats of combustion."

He then points out how all Volta tension series are in oxidation order, and relates approvingly De la Rive's view that metals in air were attacked not only by water-vapour but by dry oxygen, and that electricity is produced by any kind of chemical action in proportion to the intensity of the chemical affinity. Then he gives his numerical theory and supporting experiments ; and finally concludes : "I believe we are entitled to say that no *Scheidungskraft* exists at the contact of two metals." The following must take the place of Volta's law of the evolution of electricity :—"The difference of electric potential between two metals in contact is measured by the algebraic sum of the heat value of the chemical action going on at each."

In his theory and experiments, and all through the rest of the paper, he considers the difference of potential equal to *half* the difference of heat-values, so the above last statement must be a slight numerical slip.

The above extracts are among the most favourable. It would be easy to select passages from this, and from his other memoirs on the subject, of a more surprising character.

rists;" but they are (especially in later papers) expressed in so definite and decided a manner that they have excited a sharper controversy than vaguer and more hesitating writings could. This, indeed, may be regarded as their special merit. The main objection which can be taken to them relates to the quantitative statements; these are vigorously made, but they seem unwarranted by facts accumulated by all other observers, though, indeed, some of his own experiments certainly seem to support them. It has also been objected that he misinterprets some of his experiments.

He has got hold of the notion that the heat of combustion has some sort of relation to the Volta effect, and there I am heterodox enough to agree with him. But what the relation is, and how it acts, and what sort of potential-difference you ought to expect in accordance with theory, concerning all these things I am utterly at variance with him; and I deem it prudent not to attempt to represent views which I am unable to understand, because it is unlikely that I should do them justice.

Professor Exner, to strengthen his position, adduces a large number of very simple experiments (such as connecting first one Daniell and then two Daniells to an electrometer, and observing that in the second case the deflection is double the first), and from them he obtains equations proving algebraically that Zn/Cu = 0. Considered as conundrums these equations are ingenious, but it is a waste of time seriously to discuss them as Herr Julius has done in an elaborate manner. To suppose that such everyday experiments as these are in direct contradiction of the contact theory is scarcely complimentary to the great men who have held, and who still hold, that view.

Dr. C. G. Knott, in 1879,* examined the contact force between plates of the same metal at different temperatures, using the condenser or Kohlrausch method. He found that iron, copper, zinc, and probably tin, were negative when hot to the same metals cold; and the effect increases uniformly with temperature. But it is permanent, remaining after the hot plates have cooled down; hence it must be due to oxidation.

A slow oxidation proceeds with time alone. Time-curves are logarithmic like cooling-curves, and the most oxidisable metal varies most quickly both for time-variation and temperature-variation. There seems to be a surface-condition of a metal proper to each temperature which no polishing can change, for it establishes itself in a few seconds after cleaning, and only changes with temperature.

Mr. S. Lavington Hart, in 1881†, describes a mercury-dropper where the mercury is contained in a funnel, and is connected with an electrometer by an iron rod dipping into it. The drops form inside an iron inductor, and they fall negatively charged. Mr. Hart so far ignores any Volta force that he considers the arrangement as an inversion of Lippmann's electrometer, the advancing drops being oxidised. It can plainly be regarded, however, as a mere Fe/Hg contact arrangement; and that is what I suppose it to be. He makes two interesting modifications; the first is to replace the air round the dropping mercury by coal-gas; the electrical effect is then zero. This is interesting, because the exuding drops of mercury, unlike most pieces of metal, expose to the coal-gas a virgin surface which has probably contracted no condensed air-sheet; only coal-gas is a rather sophisticated substance for it to be first exposed to. If the experiment is regarded as sufficiently direct and simple, this fact lends support to the view that Volta forces depend on the medium surrounding the metals.

The second modification is to bring an earth connected iron bar close to the drops, and to show that it reduces the deflection. Mr. Hart thinks it reduces the oxidation by proximity; and certainly, provided the obvious action of a mere electrostatic screen has been considered and provided against, the action by proximity is very remarkable. A similar effect has been observed and more fully worked out by Pellat, in a paper published in 1882.‡ Pellat says that if he places two metallic surfaces parallel to one another and very close together (say half a millimetre more or less, variations from 12 to ·1), each metal undergoes a slight alteration of the properties of its superficial coat. The alteration takes some minutes to produce, increases with time, but tends to a limit. When the influencing metal is removed the other returns gradually to its primitive state. Lead and iron produce the largest influence effects; copper, gold, and platinum give smaller but distinct effects; zinc produces hardly any, unless it be put within a hundredth of a millimetre or so. Pellat does not attempt to account for this interesting phenomenon further than by suggesting some possible connection with the smell of metals.

Mr. Hart's theoretical views are at first sight somewhat analogous to my own, though they are by no means the same. He considers the case of two metals immersed in liquid electrolytes, and dismisses air by calling it a gaseous electrolyte. He believes zinc and copper in contact to be at the same potential, and throws the variation of potential on the air between them.§ He considers the electrical effect brought about by the electro-negative ion oxygen combining with the zinc and charging it negatively, while some electro-positive ion combines with the copper and charges it positively, "though not unless the two metals are in sufficient proximity to overcome electrolytic diffusion" (whatever that may mean as applied to this case). He thinks his mercury-dropping experiment in coal-gas is conclusive as the equality of potential of metals in contact. This, I fear, is rather rapid induction. I do not see how it follows on his own hypothesis that his arrangement is virtually a reversed Lippman electrometer.

Sir W. Thomson's dropping arrangements, or voltaic cells, in which gravity does the work instead of chemical action, are so well known that it is scarcely necessary to do more than refer to them. Mr. Hart's mercury dropper is scarcely a modification of the copper filing dropper shown in Fig. 12. Sir William also shows how to couple up such cells in series,*

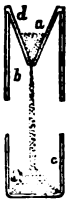

FIG. 12.—Thomson's Gravitation Voltaic Cell.

a copper filings. *b* inductor—zinc. *c* receiver. *d* copper funnel.

The copper filings drop negatively charged against electrical forces. If you join *c* and *d* by a copper wire, you can get a current flowing wholly through and with copper.

and how to construct a mechanical replenisher on the Volta principle (Fig. 13).

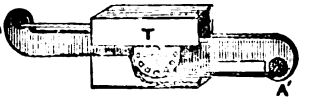

FIG. 13.—Thomson's Voltaic Induction Machine.

One of the inductors, T, is lined with one metal, the other with another, and the two connected. The carrier wheel is rotated, and the contact springs, A, A', become oppositely charged. By afterwards charging the inductors with a Daniell cell, and comparing the deflection now produced in an electrometer connected to A, A' with what it was before, measurements of Volta effect can be obtained; or of course it can be made a null method.

6. In order to give this historical sketch more completeness, it may be as well to record rapidly such other memoirs as I have been able to get acquainted with: it is in the highest degree probable that several are omitted, but I hope no very important ones. Professor Wiedemann's collection of views and memoirs bearing on the subject is at the end of the second volume of the new edition of his *Elektricität*.

Edlund has published a long paper† in which he investigates experimentally the Peltier effect; he points out clearly at the end that there is no relation between the Peltier and Volta effects; and he suggests that this is because of the contact-force between the metals and the gas or air in which they are, the fact of such contact force being, he thinks, sufficiently established by gas-batteries and galvanic polarization.‡

Majocchi, in a paper printed in *Phil. Mag.* xxx. p. 97, regards the E.M.F. of contact as due to the "adhesion" of the two metals for each other: pretty much the same idea as Sir W. Thomson's chemical action at a distance, an idea which makes the energy of the Volta effect Zn/Cu depend on, and be calculable from, the combination-heat of zinc and copper in making brass. I must return to this matter later, because it is important in itself and crucial as regards theory.

Gassiot§ made an experiment intended to show that there could be a difference of potential excited between metals by proximity without actual contact, or at any rate without metallic contact. Grove‖ also made a similar experiment.

Hoorweg¶, and also Nobili**, have a theory that all galvanic currents are really thermoelectric.

‡ Sundell investigates the E.M.F. of alloys in contact with copper, employing Edlund's method, and finds, like him, that for alloys as well as for simple metals the Peltier corresponds with the Seebeck force. The peculiar language used in this and the preceding paper may easily cause it to be imagined that they have found Volta force to agree with Peltier. In fact, Sundell is so quoted in Watts's 3rd Suppl., p. 708. Von Zahn quotes Edlund in the same sense; and indeed it is probable that Edlund himself at first thought he was investigating Volta forces thermoelectrically (Pogg. *Ann.* cxlix., p. 144).

In the article "Electricity" in the *Encyc. Brit*, p. 99, Professor Chrystal gives some clear general considerations regarding the seat of E.M.F. and the opposing views which are held with regard to it. He is judicial in his attitude with regard to them; but the mere statement of the position in so clear a form is in itself a powerful argument for the views held by Maxwell.*

Professor Fleeming Jenkin, in the last edition of his "Electricity and Magnetism," p. 216, endeavours to reconcile the contact and chemical theories. According to the chemical theory, the E.M.F. of a cell $= \Sigma(J\theta\epsilon)$; according to the contact-theory it is $C/L + L/Z + Z/C$. On these undoubted facts he proceeds to found a number of statements which are true†, though scarcely simple; in fact, they perhaps rather tend to complicate what may be held to be a simple matter.

Schönbein, in a letter to Faraday published in the *Philosophical Magazine* for 1838,‡ throws out a remarkable suggestion with regard to "chemical tendency" as the possible source of a current, or rather of "force electromotive." His language and ideas are in many respects old-fashioned and erroneous; he uses such phrases as "a current of tendency," he supposes currents with no electrolytic power to exist, and of course is not troubled about energy considerations. But I feel little doubt, that had he lived later he would have held that while *currents* were due to chemical action, *electromotive force* was due to "chemical tendency;" and this is pretty exactly my own view of the matter.

I have only just discovered this Schönbein letter; and I have also found some paragraphs in Faraday which more in detail and with fair distinctness express what I believe to be the true view. (See §§ 893—900, Exp. Res. vol. i.§)

Various observations regarding the E.M.F. of different cells are made in the series of papers still appearing in the Philosophical Magazine by Dr. Alder Wright and Mr. C. Thompson, "On the Determination of Chemical Affinity in terms of E.M.F."

For much discussion of contact-electricity and for some interesting statements of the views of Marianini, Davy, and others, refer to 'Experimental Researches,' vol. ii. p. 20, &c. From what is there said, it appears that Karsten and Marianini held a modified contact theory, placing the E.M.F. at the metal-fluid junction; and that Becquerel admitted as a possibility the efficiency of chemical attraction, as distinct from combination, something in the same way as Schönbein.

Professor Tait in his 'Thermodynamics' lends his powerful support to the contact view of the activity of the pile as taught by Sir W. Thomson.

Some work has been done in the direction of observing reversible heat-effects at metal-liquid junctions, notably by Joule, Thomson, and Bosscha. We shall have occasion to refer to this work later.

Joule in 1841 sent currents through several dilute acid voltameters with different electrodes, and measured the excess or reversible heat $H - RC^2$ generated in the whole cell; with the result that the excess of heat observed is that due to the observed back E.M.F. of the cell, minus that concerned in the decomposition of water. A table of his results is given by Chrystal, *Encyc. Brit.*, p. 91. For Maxwell on the same subject see "Elementary Electricity," p. 146.

Thomson (Math. and Phys. Papers, pp. 496, 503) says that, of two decomposition cells, one with zinc cathode, the other with platinum cathode, the former showed the most heat when the same current was sent through both. Separating the electrodes by a porous cell, zinc cathode showed more heat than zinc anode, but platinum anode more heat than platinum cathode*. He speaks of the local heat developed at a tin surface, and shows that it is greater where hydrogen is liberated than where tin is dissolved; and suggests thermal observations on four dilute-acid voltameters in one circuit with zinc and platinum electrodes, arranged according to the permutations—zinc-zinc, zinc-platinum, platinum-zinc, and platinum-platinum. Thomson attributes the extra heat at an electrode to opposing chemical affinities which have to be overcome—a doctrine of "chemical resistance."

Bosscha examines and develops all these matters in a series of interesting papers published about 1857.† He attributes the development of local heat, at a cathode against which hydrogen is liberated, to the change of hydrogen from the nascent condition to the ordinary one—in other words, to the energy of the molecular combination H, H. He finds the electromotive forces exhibited by this local generation of heat at the surface of different metals in acid to have the following values in volts:—

Pt	Fe	Cu	Sn	Hg	Zn
·45	·49	·64	·86	1·2	1·2

One more memoir I must mention before closing this historical sketch and discussion thereon, a valuable communication by Bouty to the *Journal de Physique*‡, "On Thermoelectric Force at Contact of Metals and Liquids, and on the Peltier Effect thereat." He finds the Peltier coefficient at a junction of copper with salts of copper eighty times as great as at an iron-zinc junction, and eleven times as great as bismuth-copper. He also

---

tricität, ii., p. 985, and Nobili, *Bibl. Univ. de Genève*, xxxvii., p. 118. But Prof. Hoorweg seems bitten with the same idea in recent times, and in 1879-80 writes long papers in proof that all current-energy is due to absorption of heat at junctions!

* Although this article is, or ought to be, easily accessible to everybody, there is one important suggestion in it which it is as well to quote, viz., that contained in the following sentence:—"We are so ignorant of the nature of the motion which is the essence of the electric current that the very form in which we have put the question (as to the locality of E.M.F.) may be misleading. If this motion be in the surrounding medium, as there is great reason to believe it to be, it would not be surprising to find that speculations as to the exact locality of the E.M.F. *in the circuit* were utterly wide of the mark." Prof. Willard Gibbs suggested something of the same sort at Montreal, though in a rather vaguer form. I do not myself feel any doubt that a precise location can be given to the E.M.F., notwithstanding that much of the current energy exists in the medium. The most complete attention to the distribution of energy in circuits which has yet been bestowed on the subject has been given by Prof. Poynting in his remarkable memoir (*Phil Trans.*, 1884), and he therein locates the E.M.F. of a battery exactly where I do myself.

† Except, indeed, a doubtful statement at the end of No. 2 and an erroneous bit of reasoning at the end of No. 4, though the conclusion drawn is correct.

‡ Schönbein, *Phil. Mag.*, vol. xii., pp. 225 and 311. The two most striking sentences are here extracted:—

"Before closing my letter, allow me to communicate to you in a general manner the view which I have taken of the subject in question. In the first place, I must tell you that I am by no means inclined to consider mere contact in any case as the cause of the excitement of even the most feeble current. I maintain, on the contrary, in accordance with the principles of the chemical theory, that any current produced in a hydro-electric voltaic circle is always due to some chemical action. But as to the idea which I attach to the term 'chemical action,' I go further than you and M. de la Rive seem to go; for I maintain that any tendency of two different substances to unite chemically with one another must be considered as a chemical action, be that tendency followed up by the actual combination of those substances, or be it not; and that such a tendency is capable of putting electricity into circulation."

And on page 314 he explains this last phrase, which he has elsewhere called a "current of tendency," thus:—

"As what I term a current of tendency is no doubt in some cases nothing but that electrical state which the Voltaists consider to be the effect of their 'force electromotive,' or of contact, it appears to me that, from some of the facts above stated, a specific and most important conclusion regarding the theory of the pile can be drawn. Even if we grant to the Voltaists our current of tendency to be the effect of mere contact, the facts alluded to prove that such a current does not possess a sensible degree of electrolysing-power; consequently that the chemical effects of the common voltaic arrangements have nothing to do with current-electricity excited by contact."

§ Extract from Faraday's 'Experimental Researches,' vol. i.:—

"(893) The use of *metallic contact* in a single pair of plates and the cause of its great superiority above contact made by other kinds of matter, become now very evident. When an amalgamated zinc plate is dipped into dilute sulphuric acid, the force of chemical affinity exerted between the metal and the fluid is not sufficiently powerful to cause sensible action at the surfaces of contact, and occasion the decomposition of water by the oxidation of the metal, although it is sufficient to produce such a condition of the electricity (or the power upon which chemical affinity depends), as would produce a current if there were a path open for it; and that contact would complete the conditions necessary, under the circumstances, for the decomposition of water.

"(894) Now, the presence of a piece of platina touching both the zinc and the fluid to be decomposed opens the path required for the electricity. Its *direct communication* with the zinc is effectual, far beyond any communication made between it and that metal (*i.e.*, between the platina and zinc) by means of decomposable conducting bodies, or, in other words, *electrolytes*, as in the experiment already described [that of decomposing iodide of potassium without metallic contact by interposing it on blotting-paper between the platinum and the zinc of a simple voltaic cell], because, when *they* are used, the chemical affinities between them and the zinc produce a contrary and opposing action to that which is influential in the dilute sulphuric acid; or if that action be but small, still the affinity of their component parts for each other has to be overcome, for they cannot conduct without suffering decomposition; and this decomposition is found *experimentally* to react back upon the forces which in the acid tend to produce the current, and in numerous cases entirely to neutralise them. Where direct contact of the zinc and platina occurs, these obstructing forces are not brought into action, and therefore the production and the circulation of the electric current, and the concomitant action of decomposition are then highly favoured.

"(895) It is evident, however, that one of these opposing actions may be dismissed and yet an electrolyte be used for the purpose of completing the circuit between the zinc and platina immersed separately into the dilute acid; for if in the above experiment the platina wire be retained in metallic contact with the zinc plate, and a division of the platina be made elsewhere, then the solution of iodide placed there, being in contact with platina at both surfaces, exerts no chemical affinities for that metal; or, if it does, they are equal on both sides. Its power, therefore, of forming a current in opposition to that dependent upon the action of the acid in the vessel is removed, and only its resistance to decomposition remains as the obstacle to be overcome by the affinities exerted in the dilute sulphuric acid.

"(896) This becomes the condition of a single pair of active plates where *metallic contact* is allowed. In such cases, only one set of opposing affinities are to be overcome by those which are dominant in the vessel; whereas, when metallic contact is not allowed, two sets of opposing affinities must be conquered (894)."

* Showing, I suppose that while zinc attracts oxygen much and hydrogen not at all, platinum attracts hydrogen more than oxygen.

measures the metal-liquid thermoelectric E.M.F. at different temperatures, and shows that Thomson's thermodynamic formula

$$\Pi = \frac{T dE}{dT}$$

is perfectly true and in agreement with experiment in these cases also. He endeavours to see if this Peltier, or, as we had better call it for distinction, Joule or Bouty effect, can be calculated from the energies of combination. After tabulating his results alongside of heats of oxidation and heats of solution, he decides that it is hopeless, and that we must give up trying to establish a relation between these quantities. Chemical action, he concludes, only disturbs the effect by altering the surfaces, and by developing parasitic heats. They may mask, but they do not produce, the true Bouty phenomenon, which he believes is probably physical.

The difficulties of making these measurements are exceedingly great; and, notwithstanding the ingenuity and skill displayed, it seems to me possible that some error or unexpected source of disturbance may have modified the results. So far as I know, they have not yet been repeated; and I can hardly regard the experimental method used as perfectly safe.*

[TO BE CONTINUED.]

THE INSTITUTION OF CIVIL ENGINEERS.

At the meeting on Tuesday, the 24th of March, Sir Frederick J. Bramwell, F.R.S., President, in the chair, the paper read was on "The Electrical Regulation of the Speed of Steam Engines and of other Motors for Driving Dynamos," by Mr. P. W. Willans.

The author referred first to the necessity for electrical governors in arc lighting, and other cases where a constant current was required, and where the resistance of the circuit was variable. He then alluded to the irregularities in incandescent lighting caused by the resistance of the armature, the resistance of the leads, the material of the field magnets, or to these causes combined. He went on to say that there were cases in which the length of the mains, the cheapness of the power employed, and the necessity for economy in first cost, would make a reduction in the section of the leads desirable, were it not that such a reduction introduced serious irregularities in the lighting. What was required in such cases was an electrical regulator which would ensure a constant difference of potential where the light was used, rather than where it was generated. The error due to the resistance of the leads was of the same nature as, and must be added to, the error due to variations in speed when a centrifugal governor was used; and it was pointed out that centrifugal governors in no way compensated for the loss in electro-motive force due to the heating of the dynamo either from within or from without. Attention was directed to the difficulty of winding compound dynamos for each circuit, and to the fact that subsequent changes in an installation might upset the most careful compounding. The author then alluded to the well-known difficulty of ensuring that each of several machines connected to the same mains did its fair share of work, and he pointed out that a shunt machine combined with an electrical regulator effected a reduction in the loss due to the mechanical friction of the motor when the load was not at its maximum. Many of the earlier electrical governors had been designed with a view to the maintenance of a constant speed of engine, but, so far as the author was aware, none of them had had any extended practical application.

After alluding to the governors of Lane-Fox, Sawyer and Man, Andrews, Richardson, Carns-Wilson, and Westinghouse, the author stated that the older forms of governor might be broadly divided into three classes. 1st. Those in which a centrifugal governor was used in conjunction with an electro-magnet, and he observed that these were necessarily complicated, and that they combined some of the disadvantages of both classes of governors. 2nd. Those in which the electro magnet did the whole work of moving the throttle valve. These, the author considered, could not be depended on, because the electro magnet had too much to do. 3rd. Those in which an intermediate relay of power was used, which he considered had the necessary power, but had not the necessary control over it. He next referred to Mr. Jamieson's and Mr. H. S. Maxim's governors, and expressed surprise that Mr. Jamieson in his paper on the electric lighting for steamships insisted on the necessity of a self-regulating dynamo.

The author did not claim to have been the first to recognise the advantages to be expected from electrical regulation; but he believed he had been the first to secure a practical success, as his governor had been adopted in more than fifty instances. He then proceeded to describe in detail governors in which he employed a differential connection between the core of the regulating solenoid and the relay mechanism, so as to ensure that the former should move in perfect unison with the throttle-valve or expansion gear. He explained by diagrams the experimental governor made two and a-half years ago, and showed the governor itself in action, so far as its hydraulic mechanism was concerned. He described the difficulties encountered at first, and explained that these were mainly due to the core of the solenoid not moving in unison with the regulating mechanism of the engine. The two got, as it were, into cross time, and the result was hunting, and consequent serious fluctuations in the light. He explained how these difficulties were eventually overcome, and went on to describe the ordinary form of the governor as used for regulating the position of the throttle-valve. This governor was fitted with a safety arrangement, in case of the belt breaking or the main lead being severed, and was much more simple in its action than the original experimental governor. He gave figures showing the expenditure of power in the core of the solenoid, which, in the case of a 60 horse-power engine, was not more than one-half that absorbed in a 20 candle-power Swan lamp. He showed graphically, by means of diagrams, the method adopted for balancing the core by a spring, and explained how the governor could be made either more sensitive to minute changes in current, or more stable, so as to avoid oscillation in the case of sudden variations in the load. The results were given of various experiments made with cores of different proportions, with a view to determining the best for the purpose; and the action was explained of a particular form of reducing-valve, which could be used in connection with the governor where absolute accuracy was required. The author next described the governor now in use at the Edison and Swan Company's installation at Victoria Station, and gave a chart of its performance, which showed great accuracy, a variation in electromotive force of one volt being the greatest observed during four hours, although the variations in steam pressure and currents were very considerable during that time. He then described a governor suitable for controlling the expansion gears of powerful engines, and stated that the friction of the regulating mechanism in this governor did not exceed one-fifth of an ounce, and that the power available for the work was upwards of 500lb. acting through six inches. He mentioned that in addition to their application to the regulation of the speed of motors these governors might be applied with advantage to insert resistance in a circuit, where the speed of the engine could not well be varied to suit the exigencies of the lighting. He then proceeded to describe a duplex governor suitable for one of the units of a large installation, which not only determined the difference in potential in the mains, but regulated the currents generated by each unit. In conclusion, the author alluded very briefly to the use of electrical relays. These, he stated, had not yet been used, but had in many cases considerable advantages. He showed several governors, and the promptness of their action was seen as they were connected to the water main. He also exhibited some of the governors in pieces, and their details were fully explained by the aid of diagrams.

At the ordinary meeting on Tuesday, March 31st, at eight p.m., the discussion upon Mr. Willans's paper, "The Electrical Regulation of the Speed of Steam Engines and of other Motors for Driving Dynamos," will take place.

* I find that a method exactly like that used by Bouty was suggested by Clerk Maxwell, "Elementary Electricity," p. 146.

COMPANIES' MEETINGS & REPORTS.

German Union Telegraph and Trust Company (Limited).

The fourteenth ordinary general meeting of shareholders of this Company was held at the office, 66, Old Broad-street, under the presidency of Sir James Anderson.

The SECRETARY (Mr. Wm. Payton) read the notice calling the meeting and the minutes of the last ordinary meeting, which were approved as correct by the present meeting.

The CHAIRMAN then said: Gentlemen, before moving the resolution that the report be adopted, I have one or two remarks only to make. The first is one that is satisfactory in the extreme. The Berlin Company have, as you will see by the accounts, £50,000 of reserve, and in addition £18,000 of unissued capital; that is, 68,000 sovereigns in hand upon a capital which the Berlin Company represents of £300,000. That is, I think, a very satisfactory statement, for in the absence of a reserve fund no telegraph company can in our opinion be solvent. The next remark I would make to you refers to what is stated in paragraph 5 of the report. We there say that the traffic has shown a small increase in the number of telegrams, but there has been a decrease in the average number of words in each message. The decrease in the number of words has produced a diminution in the receipts which is not compensated for by the increase in the number of telegrams sent. Now, that means something that is coming to the front very fast in telegraph companies. The fact is you are aware the Telegraph Conference allows eight languages for telegraph purposes, and those languages are to be employed according to the usages of the languages. Merchants may use all the words of these eight languages for coding purposes in any manner they please, and no exception would be taken by the companies on that account. But I am sorry to say that, within the last few months especially, there have come out a number of codes utterly defiant of all language, having no relation at all to language except that they are syllabate combinations of two letters, thus making a great difference in the receipts of every telegraph company of this country. The Anglo-American Company are feeling it, the Direct Spanish Company cannot pay a dividend very much on account of this cause, and their receipts are going down, and in the German Union Company you find that the receipts are going down, and that there is no improvement by the increase in the number of messages. The merchants are taking every advantage, and I think we shall see in the course of a short time that the companies will have to cry out against such a system. I have ventilated this matter now for the first time because we all considered it, and the Indian Government and the Post Office have also the matter before them, and I dare say at the next conference in August this subject will be discussed in the interest of every telegraph administration, both foreign and English. I do not think there is any other point, happily, worth referring to. I would mention there is a decrease in our expenses of some £27, and the dividend is some 4 per cent. less than last year. Considering the opposition of the Atlantic cable, the reduction of the tariff, and the depression of trade, I think that is a very

Digitized by Google

satisfactory result. The German Union Company, with its well-placed cables between Germany and England, stands as good a chance of being a permanent telegraph property of value as any I know of. I now propose "That the report and accounts for the year ended 31st December, 1884, submitted to this meeting be and they are hereby received and adopted, and that a dividend of 5s. 6d. a share be declared, payable this day, free of income tax, making, with the previous distribution of 5s. 9d. per share, a total dividend for the year of 11s. 3d, or at the rate of £5 12s. 6d. per cent. per annum."

Mr. H. G. ERICHSEN seconded the motion.

Mr. GRIFFITH acquiesced in what the Chairman said that the report was of such a satisfactory character that it did not offer much ground for discussion. He had only one question to ask, which he did to obtain information on the point, namely, whether the new cables laid between this country and the United States were likely to affect beneficially or adversely the submarine cable from Germany to Valentia by which the Germans had direct communication with the United States? The point to which the Chairman had especially called the attention of the meeting was a most important one. If telegraph companies did confer so much benefit on commerce, he thought merchants ought to do only what was fair, and if merchants increased their profits, the profits of the telegraph companies ought to increase at the same time. He was sure that any measures which the Board thought fit to take for protecting the shareholders' interests would meet with their co-operation. Union was strength, and it might be suggested that the companies should act together in discussing such a question. He was glad to hear that the Post Office were inquiring into the matter, for it was a subject that affected imperial as well as individual affairs. He thought with such a combination, and with the talent which the shareholders had the advantage of on the telegraph Boards, their interests would be fully protected.

The CHAIRMAN, in answer to Mr. Griffith's question, said: I may perhaps refer to the Berlin Company's report, in which they say that the Mackay-Bennett Atlantic cables, "have deprived us of a fraction, though a very small one, of the traffic." They point out that the Valentia cable, which is laid from Valentia in Ireland to Emden in Germany, gives such very rapid communication that we are able to retain practically the whole of the traffic, and no doubt we should do our best to continue to do so. Still, competition and low rates cannot always be good.

The resolution was then put to the meeting and carried unanimously.

On the motion of the Chairman, seconded by Mr. John Denison Pender, Count Oscar von Reichenbach was re-elected to his seat at the Board.

Mr. FORD next moved and Mr. GRIFFITH seconded the reappointment of Mr. Henry Dever as auditor for the current year, and the motion was unanimously agreed to.

The CHAIRMAN: That is the end of the business, but I may add, in reference to what Mr. Griffith said, that I find that the average time occupied in transmitting a message from Germany to New York is one hour.

Mr. JOHN PENDER, M.P.: I think before we part that we ought to pass a vote of thanks to the Chairman and Board of Directors. The question which the Chairman referred to just now in regard to this coding is one which I am sure will require to be looked into by all the different companies. While the public as a rule are entitled to do the very best they can to cheapen the system of telegraphy, on the other hand the Directors of the companies must take care that their shareholders' interests are duly and properly protected. I am quite sure that in the hands of Sir James Anderson and the other gentlemen connected with submarine telegraphy the matter will receive the most careful and impartial consideration.

Mr. FORD seconded the motion, which was carried unanimously.

The CHAIRMAN: We are obliged to you for this vote expressing your confidence in us, and we will do the best we can to deserve it.

The proceedings then terminated.

Montevidean and Brazilian Telegraph Company (Limited).

The ordinary general meeting of this Company was held at the offices, Tokenhouse-buildings, Moorgate-street, on the 25th inst., under the presidency of Sir Thomas Gore Browne, K.C.M.G.

The report of the Directors for the year ended 31st December last stated that the Company's percentage of the gross earnings of the Western and Brazilian Company for the year were estimated at £1,860—a reduction of £380 as compared with the preceding year, or of about £900 as compared with 1882. The Directors were informed that this serious diminution in the Company's income arose mainly from the great reduction in rates which competition had compelled the Western and Brazilian Company to adopt. The balance to the credit of revenue account amounted to £582, out of which £500 had to be set aside for redemption of debentures, leaving a net balance of £82, which would not admit of the payment of any dividend, and would be carried forward to next account.

On the motion of the CHAIRMAN the report was adoped, and the retiring Director, Mr. Charles Cameron, M.P., and the auditor, Mr. W. S. Ogle, were afterwards re-elected.

Direct Spanish Telegraph Company (Limited).

By the report of the Directors ended 31st December, 1884, to be presented at the general meeting of shareholders, at the Cannon-street Hotel, on Monday, the 30th inst., the accounts for the half year ended 31st December, 1884, show a balance to the credit of profit and loss of £4,486 0s. 9d. The traffic receipts show a falling off of £318 17s. 4d. as compared with the corresponding half year of 1883. This decrease is principally due to the quarantine regulations in Spain during the prevalence of cholera in the Mediterranean. The original Bilbao cable, as mentioned in the last report, broke down on the 17th July, and continues interrupted. The new Bilbao cable and the Marseilles-Barcelona cable have continued in perfect working order. After applying £335 14s. 7d. to close the preliminary expenses account, there will remain a balance of £4,150 6s. 2d., of which it is proposed to put £4,003 14s. 2d. to the reserve fund, which will then amount to £5,000, and to carry £146 12s. to the next account. On the 14th of January the Directors issued the following circular to the shareholders; since then another break has occurred in the original Bilbao cable:—"Since the last half-yearly report was issued, in which it was stated that the Directors did not contemplate restoring the original Bilbao cable at present, another break is known to have taken place in it, and the Board have, after careful consideration, come to the conclusion that a thorough examination of the whole cable is necessary. This, therefore, will be undertaken as soon as the season permits, and it is hoped that the exact amount required for the re-instatement of the cable may be known before the half-yearly meeting in September. In the meantime the reserve fund being practically exhausted, the Board are advised by eminent counsel that no dividend can properly be paid upon either class of the Company's shares until adequate provision has been made for the re-instatement. While they much regret to announce that the usual dividend cannot, under the above circumstances, be paid next March upon the Preference Capital, the Directors would remind the Preference Shareholders that their dividend for the past half year, and any further dividends which may have to be withheld from them, will be payable (under the terms on which the shares were issued) out of the first available profits of the Company. The new cable continues in perfect working order, and the revenue for the past half year was, as nearly as possible, the same as for the corresponding half of 1883. Since the last general meeting Mr. Bannatyne and Mr. Scott, in consequence of engagements with other companies, have resigned their seats at this Board." Sir James Anderson and Mr. Etlinger are the Directors retiring by rotation, and, being eligible, offer themselves for re-election. The auditor, Mr. Herbert R. Duke, retires, and offers himself for re-election.

Business Notice.—We are asked to state that Mr. Henry Edmunds has retired from the firm of Messrs. Edmunds and Goolden, electrical engineers, of Westminster and Halifax, and that Mr. A. B. Trotter, B.A., Cantab, the inventor of the Trotter Dioptric system of light distribution, has entered into partnership with Mr. W. T. Goolden, M.A., Oxon, and, with him, will continue the business of the late firm under the style of Goolden and Trotter.

NOTES.

NOTICE OF REPAIR.—The cable between Maranham and Para is repaired.

THE ELECTRIC LIGHT IN TOURS.—Advices from France inform us that the town of Tours is about to be lighted by electricity.

THE ELECTRIC LIGHT IN SPAIN.—The next installation of the electric light in Madrid will be laid down in the Theatre de la Princesse.

PRINCE BISMARCK'S BIRTHDAY.—On Tuesday last, in Berlin, the end of the procession was brought up by the men of the Berlin Chemical Factory, carrying electric lights instead of torches.

THE TELEPHONE IN THE PHILLIPINE ISLANDS.—Telephonic communication is about to be established at Jolo (Phillipine Islands) between the outlying forts and residence of the Military Governor.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 20th March amounted to £3,258. The traffic receipts for the week ended 27th March amounted to £3,307.

CORRECTION.—In our report of the last meeting of the German Union Telegraph and Trust Company we stated, by a typical error, that the dividend was some 4 per cent. less than that declared last year. It should have been ¼ per cent.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 27th March were £2,623, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE WEST AFRICAN CABLE.—The Chamber of Deputies, at Lisbon, sanctioned on the 30th ult., the contract concluded by the Government on July 9th last year, for the laying of a cable establishing telegraphic communication with the West Coast of Africa.

ELECTRIC TRAMWAYS IN AMERICA.—The Daft Electric Light Company has shipped to Baltimore a fifty horse-power dynamo, which will be used for generating power for running cars for the Baltimore and Hamden horse-car line, about two and a-half miles in length.

RECKENZAUN'S TRAMCAR.—As will be seen in another column, a trial was made on Tuesday last of Reckenzaun's electric tramcar, on the line of tramway the property of the South London Tramways Company, with satisfactory results. Except in a few matters of minor detail, the trial proved a great success.

THE ELECTRIC LIGHT IN GUATEMALA.—Since the commencement of the year the Government of Guatemala have installed the electric light in that town. Two turbines of 100 horse-power each, established at a distance 4,500 metres (2·79 miles) from the centre of the town, supply the necessary driving power.

THE SOUDAN TELEGRAPHS.—On Tuesday evening the third Air Line Section Telegraph Battalion Royal Engineers received a sudden order to proceed by train immediately to Gravesend, and embark on the "Ghoorka," for Suakim. When the order was received the men were engaged in bidding farewell to their friends in various portions of the town, and men of the Pontoon Troop had to be sent in all directions to apprise them of the intelligence.

THE SS. "DACIA."—The steamship "Dacia," belonging to the India Rubber, Gutta Percha, and Telegraph Works Company, left on the 2nd inst. for Key West, Florida. She is chartered by the International Ocean Telegraph Company, of New York, and has on board some heavy cable for the part renewal of the 1869 Havana-Key West cable. The new cable is of a type specially manufactured to resist the destructive chemical action of the bottom met with off Key West.

THE IMPORTATION OF RUBBER AND GUTTA PERCHA.—In 1884 there were imported into the United Kingdom 198,000 cwts. of caoutchouc, valued at £2,266,870, as against 227,422 cwts., valued at £3,618,276 in the previous year, and 179,907 cwts., valued at £2,729,298 in 1882. Imports of gutta percha are also less in amount, and were as follow :—62,713 cwts., valued at £462,746, in 1884; 63,073 cwts., valued at £468,388, in 1883; and 72,681 cwts., valued at £537,396, in 882.

THE TELEPHONE AND THEFT.—A tramp at Lismany, in Ireland, recently walked off with a coat belonging to one of the *employés* of Mr. Pollok, of Sycamore-hill. Intelligence was at once telephoned from the house to Ballinasloe. Policemen were set to watch the different entrances to that town from Lismany, and in the evening a stranger, who appeared to be carrying something bulky upon his person, was arrested, when the coat described by the telephonic message was found upon him.

MILLAR'S PATENT COVERED RIBBON WIRE.—We are in receipt of some specimens of Millar's patent covered ribbon wire, No.'s 8, 10, 12, 14, and 16, for the coils of dynamos, motors, &c. It is claimed that the ribbon wire, being nearly rectangular in section, may be coiled into a smaller space than round wire, giving thus a higher efficiency ; also that its great flexibility permits of its being coiled up with only a fraction of the strain required for round wire, and that a saving of labour and risk of damaging the insulation is thus arrived at.

THE ELECTRIC LIGHT IN GERMANY.—Although the Edison Company have now obtained a favourable decision against the Swan Company in respect to the use of the filament lamp, they are not without competition in Germany. In a case of interference between Edison and Bernstein the hollow carbon of Bernstein was declared independent of the Edison claim, and Bernstein lamps are now sold in Germany as usual irrespective of any claims of the Edison Company. We understand that the Bernstein Electric Lamp Company are about to commence manufacturing in England.

THE ELECTRIC LIGHT IN BRUSSELS.—The Administration of Posts had proposed to light electrically the offices of the Temple des Augustins, as the heat thrown out by the gas very greatly inconveniences the *employés* there. It appears, however, that for the accommodation of the dynamos and engines it was necessary to obtain the sanction of the Communal authorities for the erection of an annexe, and this sanction has, up to the present moment, been withheld. The electric light will enter largely into the illuminations on the occasion of the birthday of the King of the Belgians on the 9th instant.

ELECTRIC LIGHT AT A SHALE MINE.—Messrs. Young's Paraffin Light and Mineral Oil Company have adopted the electric light at their Newliston mine, near Edinburgh. Two powerful 16-hour arc lamps are used, hoisted on poles 50ft. high, and give a very brilliant light over the whole working space above ground. The dynamo is driven by the workshop engine, and is arranged to slide on its seat so that the belt can be tightened or slackened when running. The work was carried out by Messrs. Henry Bennett and Co., electric light engineers.

Glasgow, to specification by Mr. Alexander Morton, consulting engineer.

THE SS. "MAGNETA."—We regret that grave doubts are entertained as to the safety of the "Magneta." The vessel left the Thames nearly a month ago on her voyage to Singapore, but has not been seen nor heard of since leaving the Channel. The underwriters on Wednesday were offering 70 per cent. premium on the insurance, which indicates the feeling of a total loss. It is feared that a collision has occurred, both vessels being totally wrecked. We trust that this surmise may prove unfounded, and that even if the vessel be lost the crew may be on board some sailing vessel that as yet has not touched port.

THE TELEPHONE IN FRANCE.—The public are recognising, little by little, the advantages offered by the telephonic system. The number of new subscriptions tendered last week was 32, as against 19 for the previous week. There are now 56 call stations in successful operation in Paris. The municipal council have not yet decided upon the renewal of the agreement with the Société Générale des Téléphones. This agreement will expire on the 1st of next month. The question will probably be brought forward during the extraordinary session about the middle of April. M. Villard will then, we are informed, propose to the council the prorogation of the agreement in order that other arrangements may be entered into with a view to the abolition of monopoly.

UNIVERSAL READING OF TIME.—Mr. Parker-Rhodes has favoured us with his views on the subject of a universal meridian. To accomplish this he proposes to take a line from a centre point between south and north in the east, to meet a similar point in the west, to encircle the earth, and establish a true prime meridian for all scientific routine and international work, under a universal designation of the day of twenty-four hours. Electricity would be the agency to denote the instant to regulate the observatory clocks of the different nations, and by them the railway clocks could be set. There is nothing very new about this proposal. It is an extension of the principle of universal notation and nomenclature, about which so much has been said of late.

THE ELECTRIC LIGHT ON TORPEDO BOATS FOR THE SPANISH GOVERNMENT.—It has been decided to fit the two torpedo boats which are being built at Messrs. Thorneycroft's for the Spanish Government with the electric light, both for search light purposes and for lighting the interior parts of the boats, using the same machine for both circuits. The Anglo-American Brush Electric Light Corporation are supplying for the purpose one of their special slow speed Victoria dynamos, and are fitting the cabins with their Victoria incandescent lamps, in specially designed mountings, which have proved to be suitable for the service on board of several of Her Majesty's ships. The dynamos are to be driven by Messrs. Brotherhood's three-cylinder engines, coupled direct to the dynamos.

ELECTRIC SEARCH LIGHTS FOR OUR GUN BOATS.—The necessity for supplying our war ships with the electric light is now thoroughly recognised, and the furnishing of gun boats with the requisite dynamos and engines is now being rapidly pushed forward. Amongst the latest additions to the list of ships provided with electric search light apparatus are the "Leander," the "Racer," and the "Mariner," each of which has been fitted with a special slow speed Victoria dynamo, manufactured by the Anglo-American Brush Electric Light Corporation. These compact dynamos are coupled to 3-cylinder Brotherhood engines; and, in addition to providing the current for the search lights, some of them are also used to furnish the current for the Victoria incandescent lamps which are used for below-deck illumination.

ELECTRIC LIGHT IN BARNSLEY.—The New Oaks Colliery has been lighted electrically. The installation comprises 150 Muller incandescent lamps. The whole of the surface, including manager's house, offices, engine houses, mechanic and lamp shops, waggon ways, yards, pit bank, screens, loco. shed, coal washers, boiler houses, and brick sheds, including the pit bottoms and principal roads, were lit and gave great satisfaction. Each lamp is controlled separately, switches and safety fuses are inserted into each main branch and lamp circuit. The dynamo machine is driven from the fan engine, and is of a self-regulating type. This is the largest electric light installation that has ever been put into a colliery. It was erected and lighted by the Simplex Electric Light Company, Valley Mills, Eccles, Manchester, under the superintendence of their electrician, Mr. F. F. Bennett. The installation has given unqualified satisfaction.

DEFENCE OF SUAKIM BY MEANS OF THE ELECTRIC LIGHT.—The electric light having been found to be so useful in protecting our troops from surprises, and enabling them to watch the movements of the enemy even on the darkest night, it has been determined to provide the garrison at Suakim with two powerful search light projectors, and the requisite dynamos for generating the feeding current. These will shortly be supplied from the works of the Anglo-American Brush Electric Light Corporation. The work on the Suakim-Berber railway will also have the advantage of an electrical plant for enabling progress to be made with it both by night and by day. Groups of Brush arc lamps, to the number of 32, supplied with current by four Brush dynamos, and connected in circuit by means of insulated cable sheathed with iron wire, have been supplied from the Brush Corporation's works for this purpose. Parson's engines, manufactured by Messrs. Kitson and Co., of the Airedale Foundry, Leeds, will supply the necessary driving power.

PRESENTATION AT THE CITY AND GUILDS OF LONDON INSTITUTE.—On Thursd ay, the 26th ultimo, the day students of the Technical College, Finsbury, presented to Mr. T. Mather, assistant in the Electrical Department, a non-magnetisable silver chronograph on the occasion of his leaving the college to proceed to his new appointment at the Central Institute. The chronograph is keyless, reads to small fractions of a second, and is so arranged that it can be started, stopped in any position, or have both hands brought back to zero as occasion requires. On the outside the monogram T. M. is engraved, while inside the case is the following inscription:—"Presented to T. Mather by the day students of the Technical College, Finsbury, as a mark of their appreciation of his uniform kindness and attention." The presentation took place at an entertainment (the first of its kind) given by some of the students, Professor Ayrton presiding. Professors Armstrong and Perry, the demonstrators, assistants, and staff, together with nearly all the students, attended to do honour to Mr. Mather, and one and all united in wishing him health and prosperity in his new sphere of work.

THE BUDGET—POST OFFICE TELEGRAPHS.—The telegraphs decreased in the Christmas quarter of the past financial year by £5,000, which was exactly what they had increased in the earlier part of the year. The increase is now £15,000. The service has not realised the hopes of the Chancellor of the Exchequer. He anticipated a receipt of £1,800,000, as against £1,745,000 in the year before. But he has only got £1,760,000—an increase of £15,000 on the year before and £40,000 under the estimate. This want of elasticity in the

Digitized by Google

telegraph revenue, says the *Daily News*, is due in all likelihood to the competition of telephones to which Mr. Lefevre alluded on Monday night in introducing his Bill for cheapening telegrams. In some ways the telephone is superseding the telegraph, and for many kinds of business communication it will continue to do so. The cheapening of telegraphic communication will encourage its adoption by larger sections of the public as a means of correspondence, and may eventually result in its familiar use by multitudes who still regard the receipt or despatch of a telegram as an exceptional and even alarming event.

THE VAN RYSSELBERGHE SYSTEM IN FRANCE.—Having regard to the alleged breaking off of the negotiations between Messrs. Mourlon and Co., *concessionnaires* of the Van Rysselberghe system of simultaneous telegraphic and telephonic transmission, we notice the following in *L'Etoile Belge* of the 24th ultimo:—In the last issue of *La Lumière Electrique* there is a statement to the effect that many of our contemporaries, and more especially *L'Etoile Belge*, have contradicted the news given by us relative to the rupture of the negotiations between the French Government and M. Van Rysselberghe. We are in a position to state that our information was exact in all its details, and it it is with some surprise that we find ourselves contradicted. We confine ourselves (says *L'Etoile Belge*) to replying that if we have ventured to question the accuracy of the assertions of a French journal it is only because we have had in our hands the actual correspondence addressed by the Administration of the French Telegraphs to M. Van Rysselberghe, as well as to the holders of his patents, Messrs. Mourlon and Co. That correspondence shows that the negotiations were not for an instant interrupted, and that their conclusion was not delayed by the departure of M. Van Rysselberghe for Spain. By advices from Madrid we are informed that the experiments between Madrid and Burgos, a distance of 250 kilometres (155 miles), have resulted in a perfect success.

THE ABSOLUTE VALUE OF THE SIEMENS MERCURY UNIT, AND THE LENGTH OF THE MERCURY COLUMN EQUIVALENT TO AN OHM.—Mr. H. F. Weber corrects the value obtained in 1876-7; according to this correction the mercury unit is equal to $0{\cdot}9529 \times 10^9 \frac{\text{cm.}}{\text{sec.}}$ (not 0·9550). In 1880 and 1882 the author used the so-called Kirchhoff method of observing the current induced in a second coil on making and breaking the circuit of another coil near it. One coil, A, was laid horizontally on the top of a stone pillar, and the other, B, was supported co-axially just above it on three legs. Both coils were wound on bronze frames, A with 644 turns, and B with 643 turns of wire 1·86 mm. in diameter. The width of the coils was 4·30 and 4·31 cm. respectively, and the radius of the outside layer 17·618 and 17·670 cm. The induced current was measured by means of a galvanometer specially constructed for the purpose. The mean of the experiments of 1880 gave the mercury unit equal to 0·9498 ohm, and the mean for 1882 0·9500 ohm, or about one-quarter per cent. less than the former determinations. The mean of 50 observations with a similar but larger apparatus in 1883 gave the mercury unit equal to $0{\cdot}9496 \times 10^9 \frac{\text{cm.}}{\text{sec.}}$, the highest and lowest values being 0·9509 and 0·9486. Hence, 1 ohm is the resistance at 0° C. of a column of mercury 1 mm.^{2} in section and 105·32 cm. long.

OVERHEAD TELEPHONE WIRES.—A small pamphlet, price one penny, has been issued by Unwin Brothers, 71A, Ludgate-hill, E.C., giving ample and valuable information on the subject of overhead wires. From it we quote the following:—"A Select Committee of the House of Commons is now investigating the subject of overhead wires; but Select Committees are slow and not sure, and those who desire to check the ever-growing nuisance and danger of those wires must not relax their vigilance. One of the chief offenders, the United Telephone Company, not deterred by its failure in 1884, is to the front again with a Bill which may be properly described as 'a Bill to relieve the United Telephone Company from the necessity of paying for the rights which it acquires over other people's property.' Railway and other companies have to pay for all the rights and easements they take over private property; but this company is to have them gratis. Its main object is, of course, to get the widest possible powers for increasing and multiplying its overhead wires. And this is just the thing which it must not be allowed to have. For these two things are quite certain: that overhead wires in towns are a source of great danger, increasing as the number and weight of wires increase; and that telephone wires can be carried underground without any danger and without any loss of working power. The only possible objection to taking them underground is the larger preliminary expense; and it is simply to save themselves this expense, and, at the same time, to escape the necessity of purchasing consents, that the company is promoting this Bill."

VALUES OF THE E.M.F. OF A DANIELL CELL.—Dr. Von Waltenhofen, with a cell in which the zinc was immersed in sulphuric acid diluted in the proportion of 1 of acid to 15 of water, has found the value D = 1·088 volt. The values which are given in old text books are all less than this. Amongst these are the values found by Müller and by Poggendorff, which are expressed in arbitrary units; but, recalculated in absolute units, they come out 0·971 and 0·922 respectively. The next group of values were determined in absolute measure, but the determinations were made by Ohm's method, which, owing to polarisation, would lead to too small a value. They are—

Von Beetz	D = 0·936	volt.
„	D = 0·887	„
J. Regnauld	D = 1·016	„
Buff	D = 1·054	„
Bosscha	D = 1·026	„

The author's determinations of the E.M.F. of the Daniell cell were the first which were made by Poggendorff's second compensation method, and also the first in which Siemens' original resistance apparatus was used. H. F. Weber found the value D = 1·0954 volt, on the assumption that one Siemens unit equals 0·956 ohm. Recalculating this value on the basis of the Congress ohm, which is equal to 1·06 Siemens' unit (or 1 S. U. = 0·943 ohm), we find D = 1·080 volt. Reynier has found D = 1·079 volt, and Alder Wright the same value. It is, however, to be noted that the last three experimenters used a solution of sulphate of zinc in the zinc cell. Kittler has found the E.M.F. of a gravity form of Daniell without partition higher than that of a cell with a partition, 1·195 volt in the former case and 1·111 volt in the latter. The author's value, 1·088 volt, was arrived at from experiments with nine different cells, the internal resistance of which varied from 0·38 S. U. to 4·1 S. U.—*Zeitschrift für Elektrotechnik.*

THE NEW TARIFF.—The *Pall Mall Gazette* remarks that the reason why the charge for addresses has not been introduced before is that the telegraph officials had maintained that the increased trouble of delivery caused by inadequate addresses more than runs away with all the profit gained by curtailing the number of words sent. Mr. Shaw-Lefevre calculates that

Digitized by Google

40 per cent. of the telegrams now sent for one shilling will, in future, go for sixpence. There will be an immediate increase of business of 30 per cent. The average receipt for telegrams, which is now 1s. 1d., will in future be 10d. The average cost of transmission will be reduced from 10d. to 8¾d., leaving a margin of 1¼d. profit on each telegram, which will yield a net profit of £180,000, as against a profit of £440,000 in the year 1881, £322,000 in 1882-4, and £225,000 in the current year. At present twenty-four million private telegrams are sent inland every year, and in future it is expected that there will be more than 30 millions. The profit will not pay much more than 1½ per cent. on the capital invested in the State telegraphs. *The Times* thinks that :—In itself it appears almost absurd that the Post Office should insist on being paid for the information without which it could not perform the most essential part of its own work. Naturally it must be the business of the Office, when it accepts the commission, to instruct its subordinates at its own cost how and where they are to execute it. In any case, if the Department repudiates the obligation and tries to shift it on the sender of the message, it incurs a manifest peril of perplexing its people and exposing itself and them to the odium of tardiness and unpunctuality. The most it can in fairness claim is that, while it continues to transmit the recipient's address unpaid, it shall be esteemed at liberty to prune at its discretion particulars of description unnecessary, in the judgment of its clerks, for the safe and prompt arrival of the missive at its destination.

A New Industry: Rubber Shoddy.—Stimulated by the enormous growth of the india rubber industry in the United States, a new article, called "rubber shoddy," of which little is known on this side of the water, is being manufactured in the States, and deserves particular attention. It is produced from " old rubber boots and shoes," which, by a mechanical process, have the fibre (cotton and wool) and other impurities removed. From this state (powdered) the rubber shoddy is devulcanised (desulphurised) by steam heat, and is brought back as nearly as possible to the natural state of crude rubber. Any one not conversant with this article will be astonished to learn to what magnitude the use of it has extended. "Old rubber boots and shoes" have become a regular mercantile article, and are quoted in the journals the same as crude india rubber. The price fluctuates according to the supply and demand, varying from 3d. to 6d. per lb. It is estimated that from 12,000,000 to 15,000,000lbs. are collected annually in the United States, and are used up entirely in the manufacture of rubber shoddy, which in turn is consumed in connection with crude rubber in the production of india rubber goods. But for the substitution of this material, the value of crude rubber would necessarily increase considerably, as can be seen by the foregoing figures. The proportion as to its admixture, of course, depends wholly on the kind of goods it is intended for, and can readily be ascertained by experimenting. For coarser grades of work as high as 75 per cent. is being used, causing an immense saving, the value of shoddy being only about one-tenth of that of crude rubber. The rubber shoddy made by the improved process is superior to any rubber substitute, because it retains the characteristic properties of india rubber. It is thereby adapted to being treated for vulcanisation in the same manner as crude rubber by all processes hitherto employed.—*I. R. and G. P. Trades Journal.*

The American Patent Laws.—The following decisions were arrived at on the 3rd ult. in America :—(1) When an applicant seeks to overthrow a patent granted to one who, though junior in date of conception, has yet shown diligence in filing his application and reducing his invention to practice, the former must show entire freedom from laches, and doubts should be resolved in favour of the patentee. (2) It is not enough for a party to show that he was experimenting in the direction of the invention, but he must have matured his conception so that it can be materialised into an operative device. The conception which the law recognises is not that of the result to be attained, but that of the means to produce such result. (3) The specification of an application for an alleged pioneer invention is addressed to those skilled in the art as it existed before the making of the particular invention therein referred to, and is not to be supplemented and aided by knowledge of events transpiring at a subsequent period, or derived from another's invention of the same thing. (4) An occasional accidental operation of a device, varying from its usual operation, and which is at war with the principle upon which it was designed to act, is not a sound basis for a claim as an inventor to a device capable of uniformly producing similar effects. (5) The declaration of an interference is made on the assumption that the application or patent put in interference covers an operative device, but it by no means follows that such presumption is conclusive; the question of operativeness may be raised and considered in determining the question of priority. (6) The controlling issue in this contest is, in howsoever many claims or subordinate issues it may find expression, a speaking telephone. The inventor of an art and apparatus for transmitting articulate speech cannot be defeated or put under tribute by those who claim to have invented certain constituent elements, but who certainly never produced the completed invention—a speaking telephone. Bell is adjudged the prior inventor of all the issues save D and No. 1, and upon these latter two, priority is awarded to Edison.

Life of Electric Cables Sheathed in Lead.—The following is an account of some tests made the 19th Dec., 1884, by Professors Weber and Wurstemberger, upon a Berthoud-Borel electric cable, supplied by the Kinetic Engineering Company, and laid underground at Cortaillod in September, 1880. This cable, one of the first manufactured under the Berthoud-Borel process, is composed of twelve conductors, formed each of a copper wire nine-tenths of a millimetre in diameter. The cable is protected by a single sheathing of lead. The length of the cable is about 360 yards. It is placed in a trench dug along the margin of the Lake of Neuchâtel, in ground partly marshy and partly gravelly. On account of its position on the border of a lake, whose level is variable, part of the cable is sometimes under and sometimes above the water, and during the winter the ground is frequently covered with ice. In examination the cable was first exposed by digging a wide trench so as to judge of the state of preservation of the lead sheathing. The coating of gas tar which had been applied at the time the cable was laid, in order to protect the lead, completely fulfilled its object. The lead showed no trace of alteration, and on scratching off the thin coating of gas tar which remained adhering to the lead the metal was found intact and in perfect condition. The result of the tests showed that the capacity of a conductor for a kilometre of length = 0·086 microfarad; and the insulation per kilometre gave a mean of 6,026 megohms. The results obtained on the same cable on 5th May, 1883, by Drs. Kleiner, Schneebeli, and Wietlisbach, of Zurich, were :—Capacity = 0·090 microfarad and 3,700 megohms insulation. In comparing these results with those obtained on 19th December, 1884, on the same cable, the insulation appears to have augmented. This probably arises from the fact that a year ago, after certain changes had been made in the signalling instruments, for which the cable was used, a small piece was cut off the cable,

Digitized by Google

and the opportunity was taken of placing a sleeve filled with paraffin on the extremity of the cable. The copper wires emerging from the paraffin now have a higher insulation on account of the better protection of the ends.

PROPOSED UNIT FOR GAUGING THE COMMERCIAL VALUE OF DYNAMO MACHINES.—We have recently received a communication from Messrs Thompson, Dowsing, and Rew, upon the subject of a rough and ready method of comparing the value of various dynamos on the assumption that all are equally efficient, and to thus enable the purchaser, by a simple calculation, to arrive at the cheapest machine suited to his purpose. The existing method of dividing the output expressed in watts by the value in pounds sterling $\left(\frac{\text{watts}}{£}\right)$ is not altogether satisfactory, inasmuch as the factor of speed is omitted. Undoubtedly any increase of speed must also mean increase in wear and tear both at bearings and commutator, which, after all, are the only wearable parts. It has been proposed, therefore, by this firm that a fictitious life should be apportioned in each case, bearing a direct relation to the speed, and determined by a sliding rate of depreciation. The standard of depreciation might be taken at 10 per cent. for a speed of 1,000 revolutions per minute, and would be proportionately more or less according to the speed. The life of a machine would then simply represent the dividend of the fraction $\frac{100}{\text{rate of depreciation}}$, or in other words, accepting the given rate of depreciation, the owner would in that time have repaid his machine. A depreciation charge of 10 per cent., at 1,000 revolutions, would therefore mean $\frac{100}{10} = 10$ years, of 15 per cent. at 1,500 revolutions $\frac{100}{15} = 6{\cdot}66$ years, and so on. This factor would of course be entirely arbitrary, and only intended to give a relative value. The expression would then stand $\frac{\text{watts} \times \text{years}}{£}$, that is, so many watt years per £ sterling, or so many commercial units. The writers inform us that these units are not intended to represent any absolute quality, and have themselves anticipated criticism in this respect. They think that some makers may object to a universal comparison in respect to the performance of their machines. That some machines would spark more than others, and that consequently the speed would be no criterion of their life; but in reply to this they affirm that the quality is only nominal, and as in the case of a steam engine, different makers will give more or less efficient results.

THE ALEXANDRA PALACE—ELECTRICAL FEATURES.—The Alexandra Palace, under new management, was formally opened on Tuesday last. The principal attraction provided by the new caterers would seem to be an International Exhibition, but it will be some time before the exhibits are fully arranged. The whole place bears an unfinished appearance, and, although we can quite understand the reasons which induced the management to make every effort to take advantage of the Easter holidays, it is to be regretted that a postponement was not both possible and convenient. The electrical exhibits are at present of the most meagre description. Messrs. Shaw and Connolly, of Alexandra Works, Oldham-road, Manchester, show a great variety of insulated electrical wires and cables, including some main leads of enormous size covered with anti-capillary cotton, and a new insulating compound, superadded upon india rubber, which has recently given excellent results; some kinds of the cotton-covered ribbon leads; and a number of others of large sectional area which are similarly treated in regard to their insulation. To one thing, now in its experimental stage, we must accord unqualified praise. The electric light installation—in reality, a combination of four installations—promises to draw large and appreciative crowds to the North London Eden, and to be eminently satisfactory from a scientific, as well as from a commercial, point of view. The installation has been carried out by the Gülcher Electric Light and Power Company, and consists of sixty-two 2,000 candle-power and five 3,000 candle-power arc lamps, and about 300 incandescent of 5, 10, and 20 candle-power, distributed as follows:—Forty-four arcs of 2,000 candle-power and one of 3,000 candle-power are used for the lighting of the main building, and four lamps of 3,000 candle-power are placed on each tower for the illumination of the grounds. The concert room is lighted by eight arc lamps of 2,000 candle-power, and two clusters of incandescent lamps. The orchestra in the conservatory is lighted by 140 incandescent lamps of varying candle-power placed in flowers and fountains. The fountain in the Winter Garden is lighted by forty 20 candle-power incandescent lamps, in ornamental glass shades, placed so that an artistic effect may be produced. The Forestry Exhibition is lighted by three 2,000 candle-power lamps placed inside the hall, and one 2,000 candle-power lamp outside, for the illumination of the entrance. The Grove and Japanese Gardens are lighted with 14 lamps of 2,000 candle power placed on poles; and the refreshment bar and band stand are lighted with about 100 incandescent lamps, placed in clusters and singly, with coloured glass shades, suspended from the roof. The installation is driven for both the Hall and Forestry by five No. 4 and one No. 2 Gülcher low-tension dynamos, and the motive power is obtained from a Robey semi-portable compound engine of 30 horse-power (nominal) capable of indicating 100 horse-power, by Messrs. Robey and Co., of Lincoln. The dynamos are coupled together by means of the Gülcher improved exchange switch, enabling any dynamo to be cut out of circuit whilst it is running, and another machine switched on without stopping the lights. In the dynamo house the switch-board, safety cut-outs, &c., are placed; and from the arrangement of the lamps—said to be only practicable with the Gülcher system—any arc lamp in the Palace or grounds may be extinguished or lighted from this board. The incandescent and arc lamps being run from the same machine constitutes one of the great advantages of the Gülcher system. In the Grove and Japanese Garden there are two No. 4 Gülcher low-tension dynamos, driven by two 10 horse-power Ransome portable engines. Leather bands are used throughout the installation. Wrought-iron pulleys for driving the dynamos have been adopted as being the lightest and strongest pulleys in the market. The Bungalow Orchestra in the conservatory is a novel feature. At its base are cavernous recesses, dripping wells, pools, and mossy streams, with miniature water falls; the ponds are studded with water lilies, the electric light and water combinations producing marvellous effects. The floor of the orchestra is supported by these cavernous structures, and surrounded by a rustic rail and fringe of exotic plants, ferns, and mosses. The thatched roof is supported by eight gigantic palm trees, which show fruit, illuminated by electric light. The stems of trees and caves are decorated with creepers, vines, and grapes, studded with innumerable electric lights, the grapes and fruits themselves forming illuminations, the whole producing a refreshing and picturesque effect, which may be pronounced a *coup d'oeil* such as one would expect to have presented in fairyland.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 369.)

The Mechanical Forces and their Potential Energy.

The expression for the magnetic energy T may be conveniently put into another remarkable form, thus: By (50), $\Sigma F\mu h = -\Sigma F\mu F$; then by (48) and (51) we obtain

$$\left.\begin{aligned} T &= \Sigma h\mu h/8\pi - \Sigma F\mu F/8\pi, \\ &= T_0 - M, \text{ say} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (53)$$

Here the magnetic energy T is expressed as the difference of two quantities T_0 and M, of which the first is constant, being the maximum value of T. Short circuit the magnet by an infinitely permeable skin, there will be then no induction outside the skin, and T will be the greatest possible consistent with not altering the interior permeability μ and impressed force h. But it will not in general be as great as T_0. This requires there to be no polar force, so that h at any place can produce the full induction μh. But if we imagine every element of volume surrounded by an infinitely permeable skin, T becomes T_0. Should the magnet be uniformly magnetised, and of uniform permeability, it is sufficient to coat the outer surface with an infinitely permeable skin to increase T to T_0, and in other cases no skin is needed.

For the same reason as before given for T, T_0 and M are both necessarily positive. The quantity M is the same as what Sir W. Thomson calls the "mechanical value" of the magnetic system, or the amount of work that would have to be done against repulsions to build up the intrinsic magnet if it were given in the state of infinitely slender filaments, magnetised parallel to their lengths, placed infinitely widely apart. Or, reversing the operations, imagine the intrinsic magnet to be divided into infinitely slender filaments parallel to the lines of intrinsic magnetisation, and the filaments cut up into short straight pieces (though infinitely long compared with their diameters). Then if the elementary parts thus defined be infinitely widely separated from one another, and from all matter susceptible to induced magnetisation, the work done during the separation by the polar forces would amount to M. But I am unable to verify the statement that M may be either positive or negative ("Electrostatics and Magnetism," Art 731, end of p. 565). The form $\Sigma F\mu F/8\pi$ (not given in the paper quoted) shows that it must be always positive. The following are the principal forms:—

$$\left.\begin{aligned} M = T_0 - T &= \Sigma h\mu h/8\pi - \Sigma H\mu H/8\pi = \Sigma F\mu F/8\pi = \tfrac{1}{2}\Sigma\Omega_1\rho_1 \\ &= \tfrac{1}{2}\Sigma\Omega_1\rho = \Sigma F F_1/8\pi = -\tfrac{1}{2}\Sigma I F_1 = -\tfrac{1}{2}\Sigma I_1 F \end{aligned}\right\} \quad (54)$$

to understand which, it is necessary to say that $I_1 = \mu h/4\pi$ is the intensity of intrinsic magnetisation, and I the actual, the sum of the intrinsic and the induced; F_1 the polar force of the intrinsic, and F the actual polar force; ρ_1 the density of free intrinsic magnetism, and ρ the actual density, Ω_1 the potential of F_1 and Ω of F, and lastly $H = h + F$. For the intrinsic magnetisation we have

$$F_1 = -\nabla\Omega_1; \quad 4\pi\rho_1 = \text{div.}F_1 = -4\pi\text{div.}I_1.$$

Similarly, if the number $_2$ refer to the induced magnetisation, we have

$$F_2 = -\nabla\Omega_2; \quad 4\pi\rho_2 = \text{div.}F_2 = -4\pi\text{div.}I_2.$$

Lastly, $F = F_1 + F_2$, $\Omega = \Omega_1 + \Omega_2$; $\rho = \rho_1 + \rho_2$; $I = I_1 + I_2$.

The connection between the induced and intrinsic magnetisations is

$$I_2 = (\mu - 1)(F_1 + F_2)/4\pi = (\mu - 1)F/4\pi,$$

which makes the induction B to be

$$B = F + 4\pi I_1 + 4\pi I_2 = \mu(F + 4\pi I_1/\mu) = \mu(F + h) = \mu H.$$

The various forms in (54) are got by application of the elementary potential property

$$\Sigma f\mu f = \Sigma p\,\text{div.}\mu f.$$

through all space, f being any "polar" force, whose potential is p, with the assistance of the various relations following (54). The forms in the first line of (54) in terms of forces are the most important.

Now return to the subject from the impressed force point of view. (Our language may be suggestive of our believing magnetic induction to be a purely static state, but such a conclusion is not meant to be conveyed). We suppose there to be impressed magnetic force in the intrinsic magnet, of strength h at any place, which is always present. The impressed forces try to do as much work as they can. They have in any configuration of the system (referring to the external arrangement of magnetisable matter) already done the amount T magnetically, in setting up the state of induction B, which $= \mu H$ everywhere, H being the magnetic force as ordinarily understood outside the intrinsic magnet, including inductively magnetised matter, and the same with the impressed force h added, where there is h, that is, in the intrinsic magnet, which is of course inductively magnetised as well, unless its permeability should be unity. The impressed forces take advantage of all displacements of the system to do more work, if possible. If parts of the system be free to move, move they will, in such a manner as to let the impressed forces do more work, and increase T. The generalised "force," assisting a displacement dx is expressed by

$$\frac{dT}{dx}, \text{ or, } -\frac{dM}{dx};$$

since, T_0 being constant, any increase in T is accompanied by an equal decrease in M.

Any increase of permeability increases the induction and T, unless there be counteracting decrease elsewhere. A sphere of soft iron has no tendency to move anyway when placed in a perfectly uniform field of magnetic force. T is the same for any position of the sphere. But if the field be not uniform it will move so as to increase T. Any small piece of matter inductively magnetised will move in the direction of fastest increase in the square of the force of the field if its permeability be greater than that of the medium in which it moves; and in the direction of fastest decrease when its permeability is less. This is irrespective of the direction of the force. Thus iron moves to, and bismuth from, either magnet pole, and in certain positions they may move straight across the lines of force. This also happens when a wire conveying an electric current attracts iron, the motion being across the lines of force. (This is not a case of intrinsic magnetic force, but the principle is the same.)

Imagine a uniformly intrinsically magnetised magnet to be wholly surrounded by imaginary impermeable matter to begin with. There is no induction anywhere, and $T = 0$. Let outside the magnet there be matter of all degrees of permeability with no retentiveness, and divisible as much as we please, all floating in the standard medium of unit permeability. If we remove some of the impermeable matter from the surface of the magnet, the impressed forces immediately act, and some induction comes out into the surrounding space; and with it there are mechanical stresses set up, which, if yielded to by the matter, assisted by suitable guidance if required, will have the effect of bringing the most permeable matter to and driving the least permeable matter away from the magnet. All the while the impressed forces h are working, increasing T the magnetic energy, and equivalently reducing M the "mechanical value," which was T_0 its greatest value at starting; all the while doing an equal amount of work mechanically, viz., on the matter set in motion, which we may conveniently dispose of by frictional resistance. In the end, supposing we have infinitely permeable matter to surround the magnet with, the whole work done by the impressed forces will be $2T_0$, half magnetically, half mechanically. The final magnetic energy is T_0, the mechanical value, or potential energy, *nil*. The distribution of T as it rises in value from *nil* to T_0 becomes ultimately confined to the magnet alone. For in the final state, the magnet is short-circuited by the infinitely permeable skin. It is only necessary for the ends of the lines of impressed force to be connected by infinitely permeable matter, and this is most simply done by the skin. To obtain the magnetic energy T_0 that is left locked up in the magnet the impressed force must be removed; then, the equations of induction show that T_0 of heat is generated by the induced currents accompanying the subsidence of the induction.

Digitized by Google

Regarding the before given definition of the mechanical value, notice that the more slender a filament (longitudinally magnetised) is, the less important is the effect of the polar force on the induction inside, which differs little from μh, except near the ends, μh being the maximum induction h can produce itself. Thus by slitting up the magnet into filaments as described, and separating them infinitely, we have a final state in which the impressed forces have done infinitely nearly the full amount of work they can do, the same amount as if the magnet, without any slitting and separation, were short-circuited, if it be uniformly magnetised.

When work is done by external agency against the mechanical forces, as in drawing soft iron away from a magnet, we reduce T by the same amount. There is, during the motion, magnetic current in the magnet opposed to the impressed force, and the work done against h is twice the decrease in T. Half of this is accounted for by the magnetic energy returned to the magnet (becoming latent, as it were), the other half by the work done mechanically in drawing away the soft iron.

2M might be called the potential energy of the impressed forces in any configuration, being at a maximum $2T_0$ when the forces are prevented from working by an impermeable skin, and zero when short-circuited (with necessary modifications for irregular distributions of h). There are so many senses in which the energy of a magnet may be understood that it is necessary to be precise in stating one's meaning. Therefore, I repeat that by the magnetic energy I always mean the quantity T, which has the value $H\mu H/8\pi$ (or $\frac{1}{2}$ force × induction $/4\pi$) per unit volume, both in the magnet and without (and also when there are electric currents, only then it will not be the magnetic energy of the magnet alone), the intrinsic force, where there is any, to be included in the reckoning of H the magnetic force. We are thereby enabled to make use of electro magnetic ideas without bringing in the hypothetical Ampèrean currents. The inclusion of h in the magnetic force, making $B = \mu H$ always, is specially useful in simplifying both ideas and formulæ, without loss of generality. The theory of magnetism is quite difficult enough already (owing to imperfect retentiveness and variable permeability) without additional gratuitous difficulties.

To return to the mechanical forces set up by a magnet. There is a very important reservation to be made when considering the forces and the variation in the value of T as they are yielded to. The motion must be sufficiently slow to not appreciably alter the force by electric currents set up. That is, the variation of T the magnetic energy (of the magnet) does not ever give exactly the value of the generalised force, and in rapid motions it may be something very different.

For distinctness, consider a round bar magnet (intrinsic) and a round cylinder of soft iron moving in a line with its axis. As the soft iron moves, the induction increases or decreases, both in the magnet and the soft iron, according as it approaches or recedes from the magnet. From the symmetry, the lines of induced E.M.F. are circles about their common axis, and as they are conductors there are currents set up in both (there are also similar circular currents in the dielectric, but not involving waste of energy); their directions are such as to retard the increase of induction on approach, and retard the decrease on recession; hence the attraction of the magnet and soft iron is reduced as they approach, and increased as they recede from one another. More work must be done externally against the attraction in drawing away the soft iron than is done by the magnet in the reverse motion. The difference is accounted for fully, according to the laws of induction, by the heat of the indnced currents. This will be greatest in the magnet itself, less in the soft iron, and a very little in surrounding conductors. This effect has nothing to do with any lagging or retardation of magnetisation in the soft iron, which, if there be any, requires separate reckoning, but is of the same nature as the resistance to the motion of a (practically) unmagnetisable conductor in the magnetic field. Substitute a cylinder of copper for the soft iron; there is no appreciable force now when the cylinder is very slowly moved, as there was no appreciable departure from the normal attraction of the magnet for the soft iron when it was very slowly moved; in both cases the currents set up by rapid motions waste energy, as heat in the magnet and in the soft iron or copper respectively, and this waste must be externally accounted for. Or, supposing the magnet to draw the soft iron from rest at a certain distance, the kinetic energy communicated to the soft iron mass after it has moved a certain length will be less than the increase of T during the motion, the deficit being wasted by the heat of induced currents.

The following brings into a strong light the connection between intrinsic force and intrinsic magnetisation. Suppose we double the permeability in every part of a magnetic system, how will it affect the magnetic energy? That depends on whether we keep the intrinsic force constant or the intrinsic magnetisation. If we keep the intrinsic force constant, we double the magnetic energy, since we keep the actual force unchanged as well, whilst we double the induction. On the other hand, if we keep the intrinsic magnetisation constant, we halve the magnetic energy; for we halve the force everywhere, whilst keeping the induction unchanged.

Similarly, any increase of permeability outside a magnet increases T and the induction. Also any increase of permeability inside the magnet increases the induction and T provided the intrinsic force at the place is unaltered. T_0 is also increased. But if, whilst increasing the permeability at a place inside a magnet, we keep the intrinsic magnetisation constant, we reduce T.

The conduction current analogue will make this plain. In any system of conduction current kept up by impressed E.M.F., any increase of conductivity outside the seat of impressed force will increase the current, and also the heat generation; the same is true if we increase the conductivity at a place where there is impressed force, if we do not alter the impressed force. But if, whilst, say, doubling the conductivity at a certain place where there is impressed force, we halve the strength of the latter, we decrease the current and the heat generation.

(TO BE CONTINUED.)

ON THE DESIGN AND CONSTRUCTION OF DYNAMOS.

BY GISBERT KAPP.

(CONTINUED FROM PAGE 391.)

The problem to be solved in designing the field magnets for a dynamo is how to obtain a maximum of useful lines with a minimum of iron and copper, for it is the number of lines running across from the polar surfaces to the armature which determines the electromotive force developed in the armature coils. The cutting of magnetic lines of force produces in the cutting wires a tendency for electricity to flow, and the current produced by this tendency is inversely proportional to the electrical resistance of the circuit. To find the current, we require, therefore, to know the resistance of the whole circuit (internal as well as external) and the internal E.M.F. Before entering into the question of how the latter can be calculated it will be useful to say a few words about the internal resistance of the dynamo. This consists partly of the resistance proper of the wires through which the current must flow on its way to and from the outer circuit, and partly of a force impeding the flow of current through the armature coils, which, although not of the nature of a resistance proper, can conveniently be represented as such, and is called the "resistance due to self-induction." In practice, this is either neglected altogether or only roughly estimated as a loss of so much per cent. of the total electromotive force, and as we shall be compelled to establish our formulæ without any regard to such secondary matters as the increase of armature resistance by self-induction or the influence of the armature current on the field, which also tends to slightly lower the electromotive force, and is intimately connected with the former; it will be necessary to inquire somewhat more closely into the subject, so as to be able to estimate how great is the probable error which we are forced to introduce into our calculation by neglecting these things, and thus keeping the formulæ simple enough for practical purposes.

The current passing through the coils of the armature, which to fix ideas we will suppose to be a Gramme ring, with brushes set on a horizontal and field magnet poles

Digitized by Google

on a vertical diameter, magnetises or tends to magnetise its core, as if it consisted of two semi-circular horseshoe magnets forming a circle with equal and therefore repelling poles in contact. According to our nomenclature the external lines created by the armature current will leave the ring (Fig. 10)on the side of its north pole N_2, and enter it on the side of its south pole S_2. We may call these the lines of the secondary field, and in the figure they leave the ring to the right, and enter into it to the left of the vertical diameter $N_1 S_1$. The lines from the primary field, which are those useful in producing electromotive force, enter the ring above and leave it below the horizontal diameter $S_2 N_2$. If there were no secondary field the number of lines from the primary field passing into or out of the ring would be the same in all the four quadrants, but as there are these secondary lines it is clear that the total number of lines passing into the ring in quadrant I. will be greater than in quadrant II., and similarly the total number passing out of the ring in quadrant III. will be greater than in quadrant IV. The combined field will no longer be symmetrical to the vertical line, $N_1 S_1$, but to get symmetry we must imagine this line tilted into the position $N^1 S^1$. The angle of tilt will be the greater the stronger the secondary field, and the brushes should be placed nearly at right angles to this new line of symmetry. We say nearly at right angles, because through the shifting of the brushes the secondary field has also been shifted, and this has the result of tilting the combined field still a little further. It might perhaps be thought that since the secondary lines enter and leave the ring at the same side, they can have no detrimental effect on the electromotive force, and this is no doubt true as far as these lines alone are concerned. But

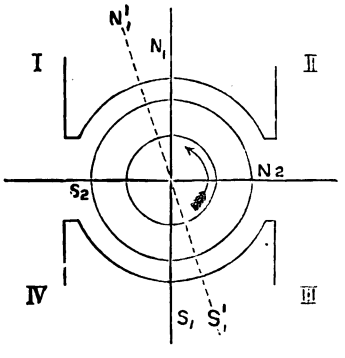

FIG. 10.

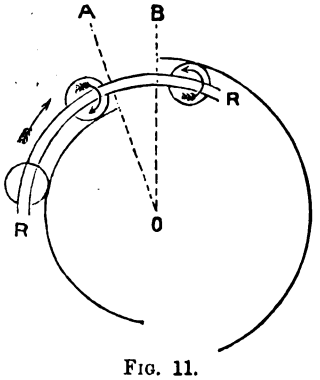

FIG. 11.

it must be remembered that, through the shifting of the brushes it becomes impossible to take full advantage of all the primary lines in each quadrant. Thus to the useful lines in quadrant I. a few opposing lines of quadrant IV. are added, and these have to be deducted from that quadrant, where they would have been useful had the diameter of commutation remained horizontal. The same takes place on the other side, and the general effect is that the shifting of the brushes results in a slight reduction of electromotive force. To minimise the evil it is evidently necessary to so arrange matters that the secondary lines find it difficult to cross the path of the useful primary lines; in other words, we must make the magnetic resistance of the secondary field as great as possible and the magnetising power of the current on the armature core as small as possible. Both these conditions are fulfilled by employing so strong a primary field that all the available magnetic conductivity of the armature core is monopolised by the large number of primary lines. As a necessary consequence of a strong field it follows that comparatively few turns of wire on the armatures suffice to produce the required electromotive force, and thus the magnetising power of these turns is only slight.

Every electric current has inertia—that is to say, it tends to flow on, even after the electromotive force which originally produced it has ceased. The flow continues until the energy contained in the current has been used up in overcoming the resistance of the conductor or other opposing forces, and if the circuit be suddenly broken this energy manifests itself in a spark. The energy of a current is proportional to its field, *i.e.*, to the number of lines surrounding the wire which carries the current. A coil has therefore more energy than a single wire, and if the coil contains an iron core, not otherwise magnetised, the energy is still further increased. This condition that the core should not be otherwise magnetised is of importance. We have seen that a given piece of iron can only accommodate a certain number of lines, and if the core be already saturated with lines from another source, it can offer no accommodation to the lines of our coil, and therefore no increase in their number can take place, in consequence of the presence of a piece of iron already magnetised to saturation. Now, the armature of a dynamo consists of a number of coils arranged all round the circumference, and enclosing an iron core. Each coil may have but one turn, or it may be composed of many turns, and the greater their number the greater will be the inertia of each coil. Any heavy body in motion may be considered as a mechanical analogue to a coil carrying a current, but for our purposes, perhaps the best and simplest illustration is that of a revolving flywheel. If started and then left to itself, the wheel will come gradually to rest in consequence of the opposing force of friction, in the same way as the current gradually ceases in consequence of the electrical resistance of the conductor. If the flywheel belongs to a steam engine with reversing gear, and we were to shut off steam suddenly and a moment afterwards open the valve again, with the valve gear meanwhile set for running the opposite way, we have the mechanical analogue of what happens when a coil, or, rather, the two sections of the commutator belonging to it pass under the brush. Whilst the latter bridges both sections the current flows on by its own inertia, in the same way as the engine keeps moving for a short time after steam is shut off. When the coil has passed the brush it has to carry the current from the foregoing coils, and this current flows in an opposite direction. This corresponds to the reversal of the valve gear and engine. This reversal of current can be represented by the mechanical model shown in Fig. 11. A circular ring, R R (only part of which is shown), is provided with heavy rollers which are made to touch and roll on an inner and outer segment, each somewhat shorter than a semicircle. Whilst rolling on the inner segment each roller revolves clockwise, and when touching the outer circle this movement is reversed. Each roller represents one of the coils of the armature. Its speed of rotation corresponds to the current, and its weight to that portion of the core which is not occupied by primary lines. When the roller passes the line O A, the force which made it rotate has ceased, but the rotation continues until stopped by friction in the journals. When the roller passes the line O B the motion is reversed, and at that moment a certain amount of friction and abrasion must take place, which in our dynamo corresponds to the sparking at the end of the brush. The angle A O B represents that part of the commutator which is covered by the brush. To facilitate the reversal of motion in each roller it will evidently be necessary to make them as light as possible, and if we could introduce somewhere between A and B a force (otherwise than friction) which would start the roller with sufficient speed, it might be made to enter the outer segment without any appreciable friction or abrasion. In our mechanical model this would be difficult, but in the dynamo it is simply done by shifting the brush so far that the coil cuts a few lines even while under the brush, and has a current started in itself a moment before it emerges from under it. These few lines are of course lost for the production of electromotive force, but the sacrifice is amply repaid by absolute freedom from sparking. The above also explains why the position of least sparking is always a little ahead of the position of maximum E.M.F. As already stated, the reduction in E.M.F. here explained can conveniently be expressed as the product of current and the so-called resistance due to self-induction. Several attempts have been made by various scientists to determine this resistance experimentally, the method being to revolve the armature in air whilst sending a current through it, and computing the increase of resistance from the difference of potential at the two brushes and the current. To eliminate the influence of the field of

Digitized by Google

the earth the direction of the current is reversed, and the means of the readings are taken. The author has himself tried this method, and after a great deal of care and trouble to exclude sources of error he arrived at the absurd result that in an armature designed for 50 volts not less than from 20 to 35 volts was required to overcome the resistance of self-induction. Evidently there must have been something wrong in the method, and on a little consideration it is easy to see where the fault lies. When revolving an armature in air, say between the centres of a lathe, its core is not traversed by any other lines of force than those belonging to the armature current, and is therefore entirely at the disposal of these secondary lines. As a natural consequence a far larger number of secondary lines is created than would be the case were the armature held in the tight grip of a strong primary field. Experiments made with an armature revolving in air are consequently quite valueless for practical purposes. The only way known to the author in which this question can be investigated is by separately exciting the field of a dynamo machine, and measuring the electromotive force created in the armature—first, when no current is taken from it, and, secondly, when currents are allowed to flow. We obtain thus the static and the dynamic electromotive force, and the difference between them (which difference naturally varies with the current) is the loss of E.M.F. due to the shifting of the combined (primary and secondary) field, and also to self-induction. From a number of experiments the author has found that the loss of electromotive force in modern machines rarely exceeds 5 per cent. of the total electromotive force, and generally averages between 3 and 5 per cent. If we now allow an average loss of 4 per cent. when designing a dynamo, the probable error will be within 3 or 4 per cent., which is a very satisfactory degree of accuracy, especially if we consider that through our as yet imperfect knowledge of the magnetic properties of different brands of iron much more serious errors are likely to creep into our calculations. In the following we shall therefore asssume that an allowance has been made for the secondary lines and for self-induction, and that otherwise these slight disturbing influences need not further be considered.

THE INTERNATIONAL SOCIETY OF ELECTRICIANS.

(FROM OUR SPECIAL CORRESPONDENT.)

(CONTINUED FROM PAGE 413.)

In continuing our notice of this Exhibition we must again put on record our surprise that the public attended in such numbers. The crush in the evening was very great, and barricades had to be erected. There is no doubt that wherever the electric light is exhibited in anything like perfection it proves very attractive. A feature worthy of consideration by our educators was the lecture explanations given by many of the exhibitors during the Exhibition to the attentive crowd that gathered around to listen, the professors from the schools and colleges taking their pupils and explaining to them the apparatus shown. One of the most interesting exhibits was that of Planté, who exhibited his apparatus for showing the similarity between globe lightning and electricity. The experiment was very attractive. A description of this will be found on p. 366 of *The Electrician*, Aug. 30, 1884. We may, however, briefly refer to it: "If a condenser, with very thin mica plate, be connected by its two armatures with the electrodes of a secondary battery of 800 couples, the condenser can be pierced, owing to the high tension of the current, and as under these conditions the quantity of current is far greater than with a source of static electricity, the effect is not confined to the production of a crackling spark; a small incandescent globule is formed, owing to the fusion of the matter of the condenser itself, and this globe moves slowly at the surface, following the points where the insulating plate which separates the armatures offers less resistance, and describing a most capriciously sinuous course" (Fig. 1.)

The experiment can be made to last for one or two minutes; it only ceases when the battery is so far discharged that the globule can no longer be maintained in a molten state between the two armatures. The slow motion of this little globule is accompanied by a strong crackling noise, and when the condenser is made to stick to the surface of a plate of hard caoutchouc a shrill and strident noise is heard, something like

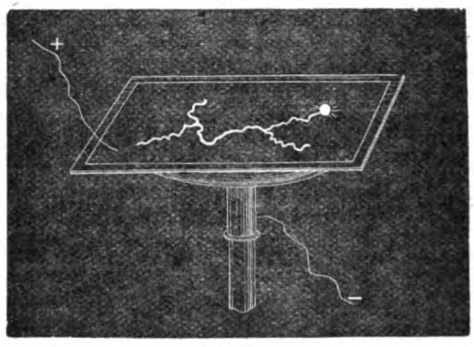

FIG. 1.

that produced by a fast revolving saw when cutting metal. The condenser is at the same time sawn and cut open over the whole course followed by the sparking globule.

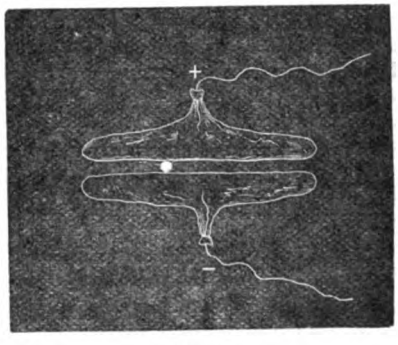

FIG. 2.

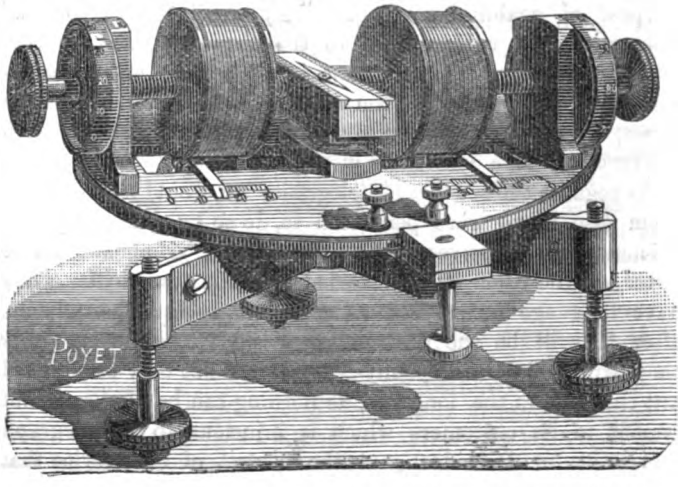
Fig. 2 shows a globe of fire travelling between the condenser plates.

The accompanying illustration shows the michrohm-mètre of M. L. Maiché, which was described in our issue of Feb. 28. It consists of a magnetised needle pivoted horizontally, placed between two parallel coils wound with wire of equal resistance. The winding is reversed in each coil, so that the influence of a current passing through the coils upon the needle is neutralised. According to the position of the coils in relation to the magnet, the magnet will remain stationary at zero or at some angle according as one coil exerts more influence than the other. The resistance to be measured is placed in the circuit between the coils, diminishing the current flowing through that coil, and hence the influence upon the needle, which, under these



conditions, moves from its normal position. The equilibrium is restored by adjusting the coil through which the stronger current flows by means of a graduated screw, and the needle may be again brought to zero.

ANSWER TO CORRESPONDENT.

T. H.—*The matter is fully explained in Dr. Fleming's article. As you say, the rules are very easy to remember and to apply.*

THE NEW TELEGRAPH TARIFF.

If the new tariff for inland telegrams, the chief features of which we were able to announce in our last issue, should be so fortunate as to be ratified by Parliament, there will be good reason to congratulate the Postal Telegraph Department and the general public on a settlement highly satisfactory to both. We say the general public, meaning the general tax-payer, who has no relish for such special burdens as, if certain persons had their way, would be imposed in this case, for the purpose of enabling a comparatively small section to send telegrams at a ruinous cost to the Treasury; and we congratulate the Post Office, because it will now enjoy a reasonable prospect of serving the public on fairly remunerative terms, or at all events on terms that will not saddle it with the certainty of a constantly increasing annual loss.

As regards the senders of telegrams, we would congratulate them also if we were permitted to do so by their noisy and officious representatives in the Press and in Parliament. These latter we know will not be satisfied with the new tariff. They have long ago forewarned us as to that. But their clients, after all, will be the final judges; and we venture to think they will find the halfpenny-a-word rate not only economical but the best in the long run, as nothing can be of permanent benefit to its customers which is injurious to the telegraph service itself. It is clearly to the interest of the service that short telegrams should be the rule; it is none the less to the interest of senders that their telegrams should be short, both on account of the greatly increased speed with which they can be despatched and the saving in the price paid for them.

These are matters which will very soon be discovered without the help of argument. For parliamentary and other advocates of cheap—very cheap—telegraphy arguments we fear will be thrown away. These gentlemen are actuated largely by motives of sentiment; but there is certainly a smack of selfishness about some of them—the selfishness which demands a Government subsidy to further special interests. The sentimental motives deserve a more respectful consideration. Mr. Alderman Lawrence, in July, 1883, gave notice that whenever the new tariff came on for discussion he would move that due recognition should be given to the fact "that much longer addresses are required by artisans and small traders than by merchants and bankers." And in a letter addressed to *The Times* in October of the same year Lord John Manners, an ex-Postmaster-General, argued very warmly for free addresses, mainly because "in proportion as the senders and receivers of telegrams are humble and unknown, will it be necessary for them, in order to secure the delivery of their telegrams, to be liberal in paying for the addresses." Mr. Fawcett, the late Postmaster-General, confessed to a preference for free addresses on similar grounds.

Now we shall not be suspected of any undue leanings in favour of the "merchants and bankers"—or, as we should prefer to call them, the professional senders of telegrams. But we are bound to say that this tenderness for the non-professional senders is quite as foolish and, if possible, rather more mischievous. If a tariff is of proved equity, and economically sound, it would be the height of folly and injustice to destroy these merits for the sake of a class which, though it may be very "humble," is certainly very small. If free addresses, as was shown in the Treasury minute of June 14, '83, would involve an annual loss of nearly £300,000, besides greatly adding to the original outlay, the sacrifice is in any case too great to be made for the problematical convenience of a very small minority. It would be far cheaper and quite as logical to let the "humbler" classes have a special rate all to themselves.

But in reality the supposed grievance is based on a misapprehension. Small tradesmen rarely use the telegraph; and a little reflection will satisfy anybody that small tradesmen will use the telegraph none the more for its being cheaper. Possibly, if local telegraphy—telegraphy within the limits of a town or city—were of much practical utility the case might be different; but we have shown over and over again that telegraphy for local purposes is not, and never can be, a satisfactory means of communication. The small tradesman has little business with the country, and sixpenny telegrams with or without free addresses will not make it for him. As to the artisan, what are the simple facts? His only need for the telegraph—and this, indeed, is a need that will be artificially created, if created at all—is in cases of domestic illness or bereavement. Telegrams of this kind may be, and in fact always are, of the briefest description; and that being the case, there is ample room for the addresses of the humblest and the most unknown.

We believe it to be a delusion to suppose that the community at large is going to be converted into a telegram-sending body when the charges are reduced. Two sixpences go to make a shilling; but for the poorer classes one sixpence is still six times more precious than a postage stamp, and twelve times better than a postcard. And, on the other hand, as regards the general public, the difference between sixpence and a shilling is not so important as to weigh very seriously when the question of telegram or no telegram is being debated. The users of the telegraph will continue to be a class, or a group of classes, who send telegrams pretty freely now, and who will

Digitized by Google

send them more freely still when the cost is lessened. These people will very readily adapt themselves to the new conditions, cutting down the addresses—especially their own—to the smallest dimensions consistent with safe delivery, and the text to the depth of their pockets. The saving, on the whole, will be so immense that the extra charge when a long message cannot be avoided will hardly be noticed.

For our own part we are not concerned to advocate one form of tariff in preference to another, so long as the free addresses are got rid of. They have weighed on the telegraph administration of this country so heavily that a reduction of the tariff has been postponed many years later than it ought to have been, because the existing system has been worked at a loss. In no other country have the addresses been allowed to pass untaxed, and we believe in no other country, consequently, has the minimum charge been maintained so high. The privilege is one that cannot be defended on any grounds whatever; and in actual practice it is grossly abused. It has been stated on several occasions by the crotcheteers of cheap telegraphy that free addresses was one of the boons conferred by the transfer of the telegraphs to the State. This is simply untrue. The companies gave free addresses, just as the State gives them now; but simply because they did not know any better at first, and, when they discovered their mistake, they were disabled from rectifying it by the competition of new companies. Attempts were occasionally made to limit the addresses; but the limitation neither pressed on the public nor relieved the companies. What the State did was to perpetuate a system which had been proved to be vicious, and one which every other state in Europe has absolutely disallowed. The new Postmaster-General has done well to follow their example by placing the English telegraphs on a business footing, which, it may be reasonably hoped, will prove a financial success as well as a public boon.

RECKENZAUN'S ELECTRIC TRAMCAR.

On Tuesday last, the first public trial of this car took place, on the lines of the South London Tramway Company. The object of the trial was to afford the members of the Battersea Vestry an opportunity of judging of the practicability of this system of working tramcars. It will be remembered by our readers* that Reckenzaun's system of propelling cars includes the use of accumulators placed on trays under the seats, and of two motors of specially light construction, placed on bogies under the car. The trays run on rollers, which greatly facilitates the changing of the accumulators, an operation which has to be performed about every two hours, when the car is worked to its full carrying capacity. There are 60 cells arranged in two rows of 30, and connected all in series. The current from these cells is led through a switch of special design, which enables the driver to put either motor into circuit alone, or both in series, or both parallel, thus providing a means for regulating the speed and tractive force according to requirements. All these operations are performed by one lever. The reversing gear is worked by another lever, which is set at the beginning of a run, but not touched during the run unless it be necessary to back on to a siding, and the current can be switched on and off by a third lever, which can also be left on during the whole time of a run. The driver has therefore only the lever for varying the power and the usual brake to look after. It is intended to add an electromagnetic brake, which will automatically come into action when the speed of the car from any cause whatever should reach 15 miles an hour. Each end of the car is provided with the controlling apparatus just described.

The weight of the car is 2½ tons, that of the accumulators 1¼ ton, and the two motors, with reversing and controlling gear, weigh just under 10½cwt. At the trial on Tuesday last, which we witnessed, the car was taken out of the depôt at 3 o'clock, and was run westward along Battersea Park-road, meeting on its way a strong contingent of vestrymen, who were taken on board, filling the car to overflowing. Thus loaded it was run up the heavy hill in Battersea Park-road, and everything went well until, on the return journey, through the shaking loose of a nut between the terminals of two cells, the current was broken, and the car stopped for a few minutes. After making the connection good again, the journey was continued up Victoria-road as far as Chelsea Bridge, and then back to the depôt. Just outside the depôt another mishap occurred, but this time not electrical. On account of a bad facing point being not properly set over the car left the rails. The front bogie was ultimately got back on to the rails by running the car backwarks and forwards over the paving, but owing to a sharp curve at that spot the hind bogie could not be persuaded to take the rails again until a straight piece of road within the shed was reached. Thus the last part of the journey was performed under as unfavourable conditions as could well be imagined, and it speaks well for the power of the Reckenzaun motor and gear that the car could be brought home by its own store of electrical power with the hind wheels bumping over the paving stones. Although the trial did not come off as smoothly as the advocates of electrical propulsion might have desired, it nevertheless proved that the scheme of working a tramcar by accumulators is perfectly feasible and practicable, and we congratulate Mr. Reckenzaun on the success already attained. There are certain matters of detail which will have to be looked after, especially a proper connection between the electrodes of the accumulators to prevent them from being loosened by the jolting of the car; and we would suggest that the lugs of all the thirty cells on one side should be soldered together and not screwed up, or if screwing be necessary that lock nuts should be employed. The accumulators, the motors, and the gear have been supplied and fitted up by the Electric Power Storage Company, of Millwall.

EXPERIMENTS IN INDUCTION AND RETARDATION.

The Director-General of the Royal Bavarian Public Works has made the following report on the tests conducted at Munich recently with the 27-core anti-induction aerial telephone cables supplied by Messrs. W. F. Dennis and Co., on behalf of Messrs. Felten and Guilleaume:—"The tests in question have in every respect given entire satisfaction. Each of the two cables that were tested is 1,300m. long, and is suspended to a separate supporting stand, which is spanned from the chief post office at Munich over the house tops to the hospital at the "Gasteig," and made fast to iron standards at intervals of about 100m. on an average. At each standard a good earth connection is provided, and made to communicate with the exterior lead covering of the two cables. For the purpose of testing the cables for induction and retardation a conducting wire of one of the cables was connected at each end with a telephone apparatus (microphone of the Ader system), and thence conducted to earth. The contiguous wire was connected with a telephone, and the two ends in same manner conducted to earth. The three earth copper wires in the centre of the cable and the unemployed 25 conductors of the cable were left unconnected. There was no trace of induction or retardation by the experiments that were made. By means of the microphone a conversation was conducted in a loud tone on the one wire, but not the least sound could be heard on the other wire, which was directly contiguous. For the purpose of comparing the clearness of tone, the same telephones were first connected with the cable wire, and then, with an open overhead wire of about the same length, but no difference could be discovered in the clearness and distinctness of tone. A cable circuit was next connected with overhead wires, under conditions just as they would be in practice, *i.e.*, the two conductors were provided with one and the same earth connection at the one end, but the other two ends with quite different earth connections, the latter

Digitized by Google

being about a kilometre apart. Under these circumstances there was also no trace of induction or retardation—not even when the twenty-five remaining conductors were all connected to earth. The earth wires in tbe cable were next connected to earth without any change being noticed. The two cables in the hospital at Gasteig were then joined together, so as to form one single cable 2,600m. long, both ends of which were in the chief post office. On repeating the experiments as described above, a conversation being conducted in a loud tone on the one conductor with the microphone, there were only disjointed and totally unintelligible sounds audible on the immmediately contiguous wire, so faint and low that they could never cause any interference with the working of a telephone. As regards the retardation, there was a diversity of opinion among those present; while some believed they noticed the tone was a little dull, others were unable to notice anything of the kind. On no account could this retardation interfere with the telephonic service. The transfer of sounds from one wire to another, however faint, was further sensibly reduced when one of the conductors, instead of being connected to the earth at the chief post office building (a water pipe), was provided by the intersection of an overhead wire one kilometre long, with an entirely different earth connection. There was then no difference as regards the clearness of tone discernible, whether the remaining conductors and earth wires were connected to earth or not. There are at present 12 conductors of one of the cables working to our entire satisfaction."

ON A PECULIAR BEHAVIOUR OF GLOW-LAMPS when raised to High Incandescence.*

BY WILLIAM HENRY PREECE, F.R.S.

1. During my recent visit to America (October, 1884) Mr. Edison showed me a very striking experiment with glow-lamps, the principle of which he had not threshed out, although he had attempted to apply it practically to the regulation of the current flowing in electric light circuits.

If *abc* be the incandescent filament of a glow-lamp, *de* a thin narrow platinum plate fixed between the limbs of a filament with an independent wire connection *ee'* sealed in the glass globe, then, if a galvanometer, G, be connected between *a*, the positive electrode, and *e*, a derived current will be observed to pass through G, and through the rarefied space *ec* when the main current is increased to a certain strength, and the filament reaches a certain degree of incandescence. The strength of this derived current will increase with the increased brilliancy of the glowing filament. Mr. Edison made for me several lamps of different forms and character to enable me to investigate the phenomenon more carefully in England, and I have the pleasure of submitting the results of those experiments to the society.

2. I used 60 Faure-Sellon-Volckmar cells freshly and fully charged up at each series of experiments. The current through the filament was measured by a specially constituted and calibrated Ayrton and Perry direct-reading spring ammeter. The galvanometer in the shunt circuit was a sensitive tangent galvanometer of the Post Office pattern. The current through the filament was regulated by varying the number of cells. The current and electromotive force through the shunt *ae* were calculated by the following method:—The resistance of the galvanometer G was 1070 ohms, and a variable resistance, R, was inserted in its circuit. When the current from a standard Daniell cell (1·07 volt) is sent through the galvanometer, we get a tangent reading, *d*, which, since $\frac{1{\cdot}07}{1070} = {\cdot}001$, is the deflection, or tangent reading corresponding to 1 milliampere of current. The deflection (d_1) given by the shunt current was first read without any resistance being inserted.

Hence

$$C = \frac{d_1}{d} \text{ milliamperes.}$$

Resistance was then added and a second reading, d_2, taken; then the resistance r of the shunt is obtained from the formula

$$r = R \cdot \frac{d_2}{d_1 - d_2} - G.$$

The electromotive force producing the current is

$$E = Cr.$$

The shunt circuit includes the rarefied space *ec*, and it is the resistance of this space that we desire to know.

All the observations were simultaneously made by different observers. While one observed the behaviour of the lamp, another read the current flowing through the filament, a third read the currents in the shunt, a fourth varied the electromotive force, and a fifth recorded the results. The electromotive force of the cells was carefully measured before and after the experiments. No photometric measurements were attempted.

3. *Experiment* 1.—The connections were made as shown in Fig. 1. The lamp (No. 4) was a short (75 mm.) filament lamp, with a platinum plate 30 mm. long and 5 mm. broad.

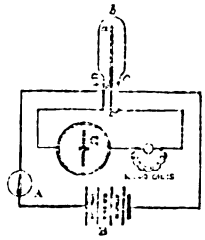

Fig. 1.

The variation of the current and the increase in the resistance of the filament towards the end of the experiment, together with the behaviour of the shunt, are very noticeable. It is quite clear that when the electromotive force attained 82 volts a critical point was reached. From that point the current in the filament remained very steady, but the resistance gradually increased. The shunt increased in resistance enormously, and the current through it diminished, although the electromotive force increased very largely. It is remarkable how steady the electromotive force in the shunt remained until the critical point was reached, when it suddenly increased, and only reached that of the main current at the point of rupture of the filament. Again the current, which steadily increased until the critical point was reached, then diminished, indicating a considerable increase in the resistance of the rarefied space *ec*. In one subsequent experiment, after the critical point was reached, no current could be obtained through the shunt.

The direction of the current is shown in Fig. 1.

Towards the end of the experiment, when the characteristic diffused blue effect in the globe was very marked, a bright arc was observed to be playing about the bottom of the limb at *c*, and it was quite clear that a bridge of conducting material was formed between *e* and *c*, which, together with the galvanometer, made a shunt to the filament.

This experiment was repeated upon different lamps, and the results were so similar that it is not necessary to reproduce the observations.

In all cases an intimate connection was observed between the blue effect and the appearance of the shunt current.

4. One of Mr. Edison's assistants showed me in Philadelphia that while the effect was very perceptible when the connections were made as shown in Fig. 1, *a* being in connection with the positive and *e* with the negative pole, no shunt current, or a very slight one, could be observed when the direction of the current was reversed. I did not find this invariably the case. One lamp (No. 8) only—a long filament lamp (150 mm. long)—which gave a marked shunt current and the blue effect when the connections were made as in Fig. 1 failed to give any current or blue effect when the current was reversed within the limits of the electromotive force at my command. Doubtless I should have got both effects if I could have raised the electromotive force. In all cases, however, the effects appeared sooner and were more marked when the connections were as shown in Fig. 1 than when the direction of the current was reversed. The effect of placing the galvanometer between *e* and *c* was the same as reversing the current.

5. As the effect might be due in some way to the material of the conducting plate (*de*) inserted between the limbs of the filament, Mr. Edison made for me lamps with copper, iron and carbon plates.

Experiments 2, 3, and 4 were then made, the connections being the same as Fig. 1.

No marked difference was thus observable.

If we examine the shunt current when the faint blue tinge appeared, it was: with carbon, 3·42; with iron, 5·85; and with copper, 3·80 milliamperes.

6. It might be affected by the extent of surface of the metal plate, therefore lamps were made with a plate of fine wire, and also of a very broad surface, but no difference was observable between these and the normal plate used.

7. Lamp No. 9 was made with a double platinum plate, thus:—

Fig. 2.

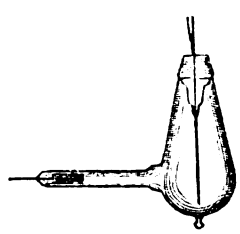

Fig. 3.

The experiment No. 5 shows that no perceptible difference was observable.

8. Although the maximum effect was produced by Mr. Edison when the plate was fixed between the limbs, he obtained a current when it was fixed in any part of the rarefied space. If the effect was due primarily to the Crookes effect, or to the projection of molecules from the carbon filament on to the metal plate, since this bombardmen takes place in right lines

we ought to have obtained effects when these lines were projected on the plate, but no effects when they could not strike the plate. Several lamps were made, which are shown in the annexed sketches.

9. The metal plate was taken from between the limbs of the filament, and placed at the end of a tube which had a portion of the filament exposed to the plate.

After the first portion of Experiment No. 6 I reversed the current through the filament. Returned to 90 volts, and repeated the experiments. Filament current readings the same as before, and also the blue effects. At 108 volts a slight blue effect was noticed in the open end of the tube.

Doubtless, if I could have increased the electromotive force, the results would have been more marked; but they were sufficient to show that the effects were evident, even though the rarefied space were greatly extended, as in the case of the tube attached to No. 5 lamp.

10. The tube was constructed so that no portion of the filament was opposed by right lines to the metal plate (Fig. 4). (Experiment 7.)

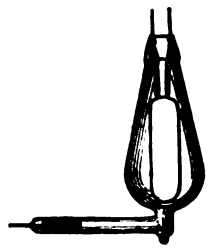

FIG. 4.

11. A lamp was constructed with three branches at right angles to each other, as shown in Fig. 5, and each metal plate taken in succession, but no results were obtained. (Experiment 8.)

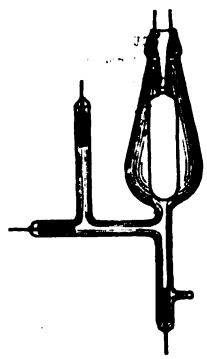

FIG. 5.

12. Professors Liveing and Dewar (*Proc.* Roy. Soc., March 9, 1882), observed a "sort of flame" during high incandescence, showing by its spectrum the presence of carbonic oxide. It was strongest about the junction of the carbon thread and the positive electrode. It was, according to them, the glow of the positive pole attending a discharge in rarefied gas.

It is a common thing with glow-lamps which have the heels of the filament close together to have an arc forming across when the electromotive force at the terminals is too high. Hence in recent lamps requiring 100 volts, Mr. Swan has considerably increased the distance between the electrodes. Moreover, whenever the incandescence of the filament is raised beyond a certain limit the interior of the glass envelope is blackened by a layer of carbon, which has been deposited by a Crookes bombardment effect. When the carbon filament is fixed on copper electrodes, the interior of the glass sometimes becomes coated with copper as well as with carbon, and the line between the two is perfectly marked, showing that the bombardment takes place in right lines. Experiment 1 shows how very high the electromotive force can be carried, if it be steadily and rapidly increased, before the filament is broken; but practice shows that when once the blue effect appears, destruction is only a question of time. Hence the blue effect is an indication of the advent of disintegration, and a very useful warning of danger ahead.

13. Now it is clear that we have a combination of the phenomena above described in the Edison effect. A continuous bridge of molecules is formed between the junction of the carbon filament and the metal plates inserted between its heels. They are found deposited on the metal plate. A shunt is thus formed whose resistance is measurable, and a definite current passes. This shunt is formed just where the negative metallic connection joins the heel of the carbon filament, as we should expect from the investigations of Mr. Crookes. The current is, however, weak and variable, and it is scarcely reliable enough to be useful for practical purposes, as was hoped by its discoverer. When the critical point is reached the blue glow and flame seem to pervade the whole bulb, and the arc-like effect, instead of playing about the heel, surrounds apparently the whole filament. The result is that the current passes through the galvanometer and through the rarefied space. This is clearly shown in Experiment 1.

14. It is quite clear that the critical point is reached when the filament commences to be disintegrated by the projection of its molecules from its surface. It is here that the resistance of the filament commences to increase, and the law of radiation and light emission (*Proc.* Roy. Soc., No. 229, 1884) commences to be departed from, as was shown by me in a paper read before the British Association at the Montreal meeting.*

15. It is very evident that this Edison effect is due to the formation of an arc between the carbon filament and the metal plate fixed in the vacuous bulb; that this arc is due to the projection of the carbon particles in right lines across the vacuous space; and that it makes its appearance earlier, and is more strongly marked, when the connections are as shown in Fig. 1 than when they are reversed, because, as Mr. Crookes has pointed out, the projection proceeds from the negative to the positive pole, and it would commence at the point of least resistance. Its presence is detrimental to the life of the lamp, and as its appearance is contemporaneous with the blue effect, the latter is a warning of the approach of the critical point, and a sure indication that the electromotive force is dangerously high. It is also clear that as the Edison effect is only evident when we are "among the breakers," it is not available for practically regulating the conditions of electric light currents as its ingenious discoverer originally proposed.

SIXPENNY TELEGRAMS BILL.

In the House of Commons on Monday last, Mr. SHAW-LEFEVRE, on resuming the adjourned debate for leave to introduce this Bill, said:—Hon. members will probably recollect that two years ago a resolution of my hon. friend the member for Glasgow was carried against the Government, calling for a reduction of the minimum charge for telegrams from 1s. to 6d. In view of this resolution the Government promised to introduce a new tariff with a sixpenny minimum. In the interval, preparations have been made for the increase of business which is expected from the reduction, and about half a million has been spent on increasing the plant and adding to the wires on some of the principal lines, and it has been decided that the new tariff shall come into force on the 1st of August next. My lamented predecessor, Mr. Fawcett, who took the greatest possible interest in this subject, had not come to any determination as to what the new tariff should be, and he left no indication what his views were on the subject, but he had appointed a departmental committee to report on the financial effect of various tariffs which had been suggested. In the interval, since the resolution I refer to, I regret to say that the financial position of the telegraph service has not only not improved, but it is very decidedly worse than it was. The profits on telegrams, which for some years had been very low, gradually rose till the year 1881; but hon. members who have examined the parliamentary account for the year 1883-4 recently laid before the House under the Telegraph Act, will see, on comparing it with the account for 1880-1, that in the former year there was a surplus profit of £325,000 out of which to pay the interest on the capital invested in the telegraphs, and in last year a deficit of £19,600. The comparison, however, is scarcely a fair one, as the account for the last year includes the sum of £175,000 expended in adding to the plant for the purpose of introducing the 6d. telegram, and is therefore capital expenditure. Both accounts also contain a considerable expenditure, which is necessary year by year for extending the wires to new places, and which is, strictly speaking, capital expenditure. If the annual accounts were made out on strictly commercial principles, it would appear that the profit in 1881 was £440,000, in 1883-4 £322,000, and for the current year ending on the 31st of March next it will be about £255,000, which would pay interest at the rate of not quite 2½ per. cent. on the capital invested by the State in the telegraphs. This reduction of profit since 1881 is due mainly to the increase of salaries made two and three years ago to the telegraphists and other officers in the service which were pressed on the Government by many members of the House, and which, in the opinion of my predecessor, were fully justified; in part also by the increased cost of maintenance during the last two or three years, owing to the wearing out of posts and other plant taken over by the department from the telegraph companies. The House will see, therefore, that the margin of profit at the present time is not large and does not pay full interest on the capital invested. I should also point out that owing to the depression of trade the receipts have been very stationary the last two or three years, and that we are now subject to the competition of the telephone. The next point I have to bring under the notice of the House is the effect of the present tariff for telegrams, and how far it leads to unnecessary and unprofitable labour to the department in the transmission of superfluous and unnecessary words. Under the Act of 1868 no charge can be made by the department for addresses, and for words in the text the tariff is 1s. for 20 words, and 3d. for every five yards after. There is therefore no inducement whatever to senders of telegrams to compress their addresses within reasonable limits or to compress or limit the words of their text provided

* In this paper I pointed out from experimental data that the light emitted by a glow lamp varied apparently as the sixth power of the current. I verified this law, not only by subsequent experiments of my own, but, which is much more satisfactory, by experiments of others. Professor Kittler, of Darmstadt, and Captain Abney made, independently of each other, most careful and exhaustive measurements in this direction. I tabulated and traced them out in curves. They fully confirm the law that $L = kC^6$, but within limits, and that these limits embrace the ordinary range of a glow lamp when used for artificial illumination. As long as the resistance and the current vary uniformly together the law holds good; but as the state of incandescence is increased, a point is reached, varying with each kind of lamp, when the resistance ceases to diminish at the same rate, and eventually to increase. When this occurs the law is departed from, and the light emitted increases much faster than the sixth power of the current. The filament speedily breaks. The point of departure from the law indicates a point when a change of state occurs in the carbon filament. Disintegration probably sets in. This point ought to be determined for each kind of lamp, and it should never be allowed to be reached, for it is from this point that decay commences and rupture follows.

Digitized by Google

they do not exceed 20. The average number of words in addresses is a little over 11, of which four are devoted to the name and address of the sender and seven to that of the addressee, and the average number of words in the text is 17—making a total average of 28. We differ in our method of charge from nearly every other country in Europe; almost without exception their tariffs are based on payment per word, including the addresses, and with some low minimum charge; the result is that there is every inducement to compress the words and limit the length of addresses and text. In foreign telegrams sent from this country, where the charge is a purely word rate, the average number of words used in addresses is five; in Germany it is only four. Under our system there is no inducement whatever to limit the addresses; many firms habitually stamp their telegrams with the full name of their firm where one word would be quite sufficient. I received myself a few days ago a telegram in which 26 words were used in the address and where six would have amply sufficed. It is the same with the text of the message. Very few people take any pains to limit their words within 20, and a great many purposely fill up to 20 because they like to have their money's worth. The result is that in a very large proportion of telegrams there are superfluous words, and the plant of the department and the time of staff are occupied in transmitting these unnecessary words without any benefit to the Government or to the public. If the tariff were such as to give inducement to compress the words and to cut off what is unnecessary it is certain that the same plant and staff would transmit a greatly increased amount of business. The present annual number of inland private telegrams is 24 millions, and the average receipt from them is 13d., showing how few exceed 20 words. A very careful estimate has been made of the cost of transmitting them, and we believe that 10d. may fairly be taken as the average cost of transmitting a telegram, without taking into account interest on the plant. It will be obvious to the House that if we were to reduce the rates all round by one-half, retaining free address, our receipts for the present telegrams would be reduced by one half, or about £50,000, and our expenses would remain the same, while the increased business due to the reduction would be carried on at a loss. If we were to retain free addresses and to allow five words in the text, it has been calculated that, assuming an increase of 30 per cent. in the number of telegrams, the difference to the department, as compared with the present tariff, would be £264,000, or considerably more than the whole of the present margin of profit on the commercial account. This tariff also would not be very favourable to the public, for while it would allow any number of words in the address, the words in the text would be very limited, and it would not be open to senders to economise their words in the address in order to add them to the message itself. The fact is that if only a small total number of words can be allowed for the minimum charge, it is the interest of the senders of telegrams that they should be allowed to economise words in the address in order to add to the text of the message. It becomes, therefore, the interest both of the public and of the Government that inducement should be given to limit the words of the address, and the only way of effecting this is to charge ratably for the words used both in the address and in the message. After careful consideration of all the various tariffs which have been suggested, I have come to the conclusion that, of those which are within financial possibility, the best both for the senders of telegrams and for the Department—the one which will bring in the best return while giving the greatest latitude to the sender—is the simple charge of 1d. for every two words, with a minimum charge of 6d. We believe that, under this tariff, the average number of words used in the address will be reduced from eleven to five, of which one word only will be the average of the sender's address and four of the address of the receiver. In a very large number of cases it will be unnecessary to insert any address for the sender. The text will show clearly from whom it comes; in nine cases out of ten one word will suffice, and in the same way, though not in the same proportion, there will be great economies in the address of the receiver. There will also be great economies in the text of messages; a careful examination of great numbers of telegrams has convinced the officers of the Telegraph Department that 30 or 40 per cent. of the telegrams now sent for 1s. will in future be compressed so as to be sent for the minimum charge of 6d. Of the new business attracted by this low tariff a very much larger portion will be at the *minimum* rate. It is estimated that there will be an immediate increase of business of 30 per cent. It is thus calculated that the average receipts for telegrams will be reduced from 13d. to 10d., and that the average cost of transmitting them will be reduced from 10d. to 8¾d., leaving a margin of 1¼d. in lieu of 3d. The difference to the Department, therefore, partly in the shape of reduced receipts and partly in increased staff, will be about £180,000, which the House will see will leave us but a very small margin of profit. The tariff I have thus proposed is very much that which was suggested two years ago by a large majority of the principal Chambers of Commerce, and, I think, by the hon. member for Glasgow. The only objection I have heard to it is that it may tell somewhat unequally upon the poorer classes of the community who live in our great towns and whose addresses require fuller description than others. I should be very sorry if this class should not receive full benefit from any change. At present a telegram costing 1s. is a rare luxury to people in this class. I have applied to the telegraph offices in those parts of London and elsewhere where the working classes mainly live, and out of 24,000 telegrams only 167 can be attributed to persons in this class, or less than one-half per cent. These telegrams have been carefully examined; 156 of them were sent for 1s.; of these 71, or nearly one-half, could be compressed without any difficulty and by the exercise of very ordinary intelligence within 12 words including their addresses, so as to come within the minimum charge of 6d. The fact is, that the great bulk of these telegrams are of the simplest character, reporting the death or illness of a member of the family, or reporting the movements of the sender, and require a very few words to tell their tale. I am convinced from a personal examination of these telegrams that the senders of them will derive at least their full share in the benefit which is to result from the tariff I propose, and that the 6d. telegram will be an immense boon to the poorer classes of the community, and bring the telegraph within the reach of large numbers who cannot now afford to send messages. I have in conclusion to say that the measure which I propose will repeal the provisions of the Telegraph Act of 1868, requiring that addresses should be transmitted free of charge, and will enable the Post Office to charge a word rate for addresses as well as for the text of messages. In adopting this tariff, we shall bring our system into harmony with that of every other country in Europe, we shall put ourselves in a position to meet on better terms the competition of the telephones, and we shall be doing the very utmost which the financial position of the telegraph service permits of.

Mr. STUART-WORTLEY entered a protest against the proposal to charge for the address, and expressed a hope that that part of the scheme would not be pressed. He asked whether the shilling rate would be continued side by side with the sixpenny rate.

Dr. CAMERON believed that in diminishing the cost of telegrams there would be a great accession of revenue. He expressed approval of the halfpenny per word rate, and insisted on the importance of maintaining the address of the consignee with sufficient fulness so as to be readily intelligible. On the whole, he thought the scheme very much that which was shadowed forth by the late Postmaster-General some years ago, and, as such, the House and the public could not expect anything better.

Mr TOMLINSON thought that the Post Office had missed a great opportunity in not taking up the telephones and working them on a large scale. The use of the telephone had enormously diminished the receipts from the telegraphs.

Mr. T. P. O'CONNOR expressed dissatisfaction with the scheme as a whole.

Mr. SEXTON thought there was considerable force in the objection that under the new scheme with the addresses charged for senders of telegrams would be placed at a considerable disadvantage as compared with those under the present system. He thought it should be optional on the part of the public whether they should select the shilling rate or the sixpenny rate.

Mr. SHAW-LEFEVRE thought it would not be possible to keep up the two scales of charge together. The receipts from the telegraphs had been very stationary during the last two years, partly owing to the depression of trade and partly from the competition of the telephone. He hoped, however, that by the reduction of the charge which he now proposed, a more favourable return would be obtained.

Leave was then given to bring in the Bill.

On Tuesday the Bill was read a first time, when Lord J. MANNERS gave notice, on the second reading of the Bill, to move an amendment for the purpose of retaining free addresses.

THE COMMITTEE ON OVERHEAD WIRES.

Many of our readers having expressed a desire to have this subject dealt with by us week by week, we, in deference to their wishes, publish the following:—

The Select Committee of the House of Commons, appointed to inquire into the law relating to the control of telephonic, telegraphic, and other wires, has held three sittings under the presidency of Mr. G. W. E. Russell. The Committee has now adjourned until the 16th inst. We append the evidence of the principal witnesses.

On the occasion of the first sitting Mr. ROBERT HUNTER, solicitor to the Post Office, gave evidence with special reference to the relative position and powers of the Post Office and private companies. He said that the rights of the Post Office were defined by Acts of Parliament, the Act of 1868 having transferred the telegraphs to that department, and the Act of 1869 giving the Postmaster-General a monopoly of the telegraphs, but conferring no special powers with regard to the laying of wires. Up to 1878 local road authorities possessed an absolute veto as to the fixing of overhead wires, but in that year another Act was passed, giving the Postmaster-General an appeal against such veto to the magistrates or the County Court, and a further appeal to the Royal Commissioners. At present the Post Office, when desiring to erect an overhead wire in a town, must obtain (1) the consent of the road authority; (2) the consent of the private persons upon whose buildings an attachment is proposed, or, if the line is a pole line, the consent of the occupier of every dwelling house within ten yards of a pole; and (3) besides this, in the country the consent of the persons owning and occupying parks and pleasure grounds along the route. With regard to attachments and the erection of posts within ten yards of a dwelling house, there is apparently no right of appeal from a refusal of a consent. Mr. Hunter offers these suggestions for simplifying the existing system: that there should be an appeal in every case, except as to attachments to private property; that the Postmaster-General should give proper notice of his desire to erect a line, and that all persons who have a *locus standi* under the Act of 1863 to veto or object—whether public authorities or the owners of property affected—should have an opportunity of sending in written ojections, and that the case should then stand referred to some one tribunal having the power to deal with the matter once for all; that this tribunal should be the County Court, which has hitherto disposed of cases in a simple and inexpensive way; that the appeal to the Royal Commissoners should be abolished as unnecessary, and causing delay and expense; and that the provision requiring the consent of the occupier of every house, within ten yards of which a pole is to be erected, should be repealed, or that at least the distance should be reduced; the right of such occupiers to object with other persons interested in property along the route seeming

Digitized by Google

to be sufficient protection. With regard to underground wires, Mr. Hunter does not consider any alteration in the law necessary, except as to abolishing the appeal to the Royal Commissioners. Private companies he would place in the same position as the Post Office in the matter of overhead wires. This much as to the Post Office and ordinary telegraph wires.

In the case of telephone wires, Mr. Hunter explains that telephone companies, as licensees of the Post Office, are not entitled to any of the statutory powers which the Postmaster-General possesses as to the erection and maintenance of telegraphs. They cannot interfere with public highways, or carry wires either over or under highways, and their position has been fixed by legal decisions upon several actions against the United Telephone Company. They may not interfere with a highway in order to lay an underground wire in such a way as to cause obstruction to the public, even though such obstruction exists only during the work of laying down the wire, either with or without the consent of the local authority. In towns the road authority is, under various statutes, the owner of the surface of the street, and any interference with such surface is a trespass; and both in town and country remedies are provided for the obstruction of highways within distances varying from 15ft. to 30ft. of the centre, and persons causing an obstruction beyond such distances may be proceeded against by indictment for creating a nuisance. But with regard to overhead wires, it has been laid down in a case by the Wandsworth District Board against the United Telephone Company, respecting a wire across High-street, Putney, that the road authority in a town in whom the streets are vested by Act of Parliament has no veto upon the erection of a wire across a street, provided that the wire is suspended from supports which are not fixed upon the road; that it crosses the road at a height above the ordinary user of the road; and that it does not threaten danger or damage to the public. Road authorities in country districts, where the surface of the roads is not vested in them, have no greater rights than urban authorities; and the position of the telephone companies, therefore, appears to be that they may erect wires across a highway unless they are likely to be dangerous to the public. But, on the other hand, there are some cases in which the soil of a street is vested in a corporation, or some other body or persons, not by virtue of Act of Parliament, but as an ordinary question of property, and in such cases the erection of a wire, apart from the question of danger or nuisance, must be treated as a trespass, and dealt with accordingly. Apart, however, from the general law applicable to telephone wires, several corporations have obtained Acts giving them special powers for regulating these wires. In some of these Acts the corporation is empowered to make bye-laws (to be approved by the Board of Trade) for the inspection, execution, prohibition (except by license), and removal of telephone wires, together with a right to recover penalties against offenders; and in cases where a wire may not be erected without a license, an appeal to a court of summary jurisdiction is given against an unreasonable withholding of assent. Over and above these restrictions upon telephones, the Post Office has the power to practically forbid their erection by refusing the license which every telephone company must obtain, and in so acting is subject to no check except by proceedings in Parliament, but control of that kind is not easily exercised or very effective. This being how the matter stands as to telephones, Mr. Hunter advises that all persons desiring to erect overhead telephone wires should have the same powers as the Post Office in respect to roads; and, further, that licensees of the Post Office, and only such persons, should also have the same rights as the Postmaster-General possesses as to laying down underground wires—both provisions, however, being subject to the condition that the Postmaster-General should have notice of every intended wire and that he should have a veto upon the proposal if he considers that the wire will injure any Post Office wire, or occupy space which he will require for Post Office purposes within a limited time. With regard to electric lighting wires, the Act of 1882 distinctly forbids the laying of wires along, over or across any street or road without the express consent of the local authority, and also gives a right of appeal to a court of summary jurisdiction to any person against an overhead electric wire, even though the consent of the local authority has been obtained.

Mr. GRAVES, engineer to the Post Office, put the cost per mile of underground wires at £368, and pointed out the great difference in mileage between overhead and underground wires, a difference which was altogether in favour of the latter. It was possible to lay a large number of wires in one pipe, which became, practically speaking, a cable, whilst the number of wires possible to be run in an aerial cable was much smaller.

During the proceedings the question was raised and negatived whether the committee should take into consideration the bill promoted by the United Telephone Company.

Mr. J. BOND MORGAN, Managing Director of the United Telephone Company, said his company was formed in 1880 by the union of the Edison and Bell Companies, and by this amalgamation the subscribers to the two companies were connected with one exchange system forming the Metropolitan Telephone Exchange. There were eighteen district exchanges, and 3,447 subscribers, excluding the 300 subscribers to the Stock Exchange. Subscribers to the Metropolitan Exchange paid £20 a year, and 10 per cent. of this amount was required by the Postmaster-General as royalty. Their license from the Post Office was for thirty-one years from January, 1881, and the Postmaster-General reserved power to purchase at the end of 1890, 1897, or 1904, at a price to be settled by arbitration. This license did not allow any written messages to be delivered, and the system was strictly confined to verbal communications. The United Telephone Company, under arrangements now being concluded with district companies, would not itself work any but the Metropolitan Exchange; all others were to be worked by the various district companies holding licenses to use the patents and working under licenses held from the Postmaster-General. Prior to the extended license granted by Mr. Fawcett last year, the extension of the business of the telephone companies had been much hampered, particularly in the connection of towns one with another. This and the limit of radius and the difficulty of getting way-leaves for the running of wires had much hindered the development of business. The whole of the United Company's wires in London (about 5,000 miles in length) were overhouse wires, except in a few places, where they were run in subways. The practice of constructing overhead wires was usual throughout Great Britain and America. The telephone companies had no compulsory powers and did their entire business on sufference. Like the Postmaster-General, they passed their lines over private property without permission; but they did not claim the right to do this, and where they could not meet the views of objectors or obtain formal permissions, they removed the wires. They did not ask the permission of local authorities to cross streets, and were advised that local authorities had no such property in the soil as would entitle them to interfere with wires passing over the streets, unless the wires were placed so near the ground as to interfere with the traffic, or were in a dangerous state. This view had been confirmed by the Court of Appeal in the case tried at the instance of the Wandsworth District Board of Works. The United Company made a point of keeping the wires at such a height above the street as to clear all possible traffic, even a fire escape, as Captain Shaw could prove. The company ordinarily used a 3-strand No. 16 gauge iron wire, weighing about 10lb. to the 100 yards, with a breaking strain of from 700 to 800lb. In some cases a phosphor-bronze wire, very much the same as a hard-drawn copper wire, was used. This was a 2-strand wire, weighing about 2½lb. to the 100 yards, and had a breaking strain of about 250lb. The company also used a good many aerial cables containing from twenty to forty wires, with a 3-strand No. 16 galvanised iron wire as a core. These were suspended upon suitable iron wires, but were quite sufficient to sustain their own weight. During the five years in which the company's overground system had existed in London there had only been three trifling accidents causing injury to persons, and none of these had been caused by the breaking of a wire. The fact that the Company, without any compulsory powers, had been able to construct so many overhead wires showed conclusively that the objection to these wires was not a general one. He was aware that the cost of running wires over houses was much less than the cost of running them on posts along the sides of the streets, and vastly less than the cost of putting them underground. In fact, it would be practically impossible to put the wires underground, and in connection with this question he asked the Committee to consider one very important point. The telephone brought electrical communication to the house or office of every subscriber, and there could be no collection and delivery of telephone communication as of telegrams. The company had therefore to run a separate wire into each subscriber's office; and although a considerable number of wires might start from an exchange in one direction, they began immediately to spread and scatter, and soon separated into ten or a dozen different routes, until finally there were as many routes as there were subscribers. The cost of a single overhouse wire was not more than £2 2s. per mile, and unless there were any exceptional difficulties as to way-leaves, the whole thing would not cost more than £10 a mile. Mr. Graves, engineer-in-chief to the Post Office, put the cost of a single underground line at about £368 a mile, and if a wooden pavement, or asphalte, with concrete, had to be taken up, the cost would be very much larger. In fact the cost of underground wires would be prohibitory, not to speak of the annoyance and inconvenience caused to the public by interruption of the traffic. The telephone was of immense advantage to the public, as was evidenced by the fact that the number of communications by telephone in London exceeded the number of messages sent by telegram. The telephone enabled persons to communicate very much more rapidly than was possible by telegraph, and had this further advantage that half a dozen persons in different places might carry on a conversation together just as if they were in the same room. Now that the limits of radius formerly imposed by the Post Office had been removed, towns could be readily connected. Brighton was in communication with London, and the large mercantile centres in the north were being connected up. This had been done without any adverse effect on the Post Office revenue, which had continued to grow, and at an increasing rate since the introduction of the telephone. Generally speaking, the companies had had little difficulty with provincial local authorities, the individual members of which found the use of the telephone in conducting their business. In the metropolis, owing to the great division of authority, no general regulations had been adopted. There were thirty-eight local authorities in London, and it would be quite impossible to have thirty-eight different sets of regulations, and thirty-eight different sets of inspections. Whatever regulations were made must be uniform. The telephone companies never objected to any reasonable regulations and control by the local authority, consistent with the maintenance of their existing right to pass wires over the streets. They had only objected where the authorities had sought absolute powers to take the wires down. He was of opinion that bye-laws might be framed by the local authorities, sanctioned by the Local Government Board or the Board of Trade, and enforced by a magistrate. The proposal of the Post Office would not, in his opinion, work satisfactorily, as the delays attendant on such a scheme would seriously interfere with business. The companies thought that having regard to the importance of their work and the increasing value of the system to the public, some facilities should be given to them for carrying on their work. With this object the United Telephone Company had introduced a Bill operating in the metropolis and a radius of 100 miles therefrom. The company asked powers to run lines above or under roads, subject to various restrictions. They also asked for power to pass wires over private property upon payment of compensation for any damage done, subject to the wire not being placed within a certain distance of the ground or of the roof of the building, and subject also to a provision requiring the company to remove the wire if the owner required to use the property

Digitized by Google

for any purpose with which the continuance of the wire would interfere. The company also asked that limited owners should be at liberty to grant way-leaves during their ownership, reserving to the reversioner full rights of removal. These powers would, in witness's opinion, much facilitate the operations of the telephone companies, and would not prejudice the rights of private owners.

Mr. SPAGNOLETTI, the telegraph engineer of the Great Western Railway Company, expressed his opinion that the telephone system could not have attained its present dimensions but for the convenience of running the wires overhead, and he estimated that such wires, including poles and other appliances, cost only about £70 or £80 a mile, while underground wires would cost nearer £480 a mile. Besides that great cost, the trouble and public inconvenience of breaking up streets would render an underground system quite impracticable; and, on the other hand, the experience gained, and the mechanical improvements made in recent years, enabled engineers to erect overhead wires with perfect safety, and without annoyance to anyone.

Mr. M. HUNTER (re-called) said he had made an analysis of the powers reserved to local authorities by private Acts of Parliament with reference to telephone wires. These provisions might be classified under three heads: First, provisions giving the corporation or local authority an absolute veto upon the erection of wires; second, provisions giving such a veto subject to an appeal to a court of summary jurisdiction; and, third, provisions enabling the local authority to make bye-laws for the prohibition and regulation of telephone wires subject to confirmation by the Board of Trade. In case of disputes the matters were decided in two ways. In one case it was made a judicial matter and went before a magistrate, and in the other it was made a municipal matter, but the corporation could not make an order without the assent of the Board of Trade. There was great objection to the Board of Trade deciding on a Post Office matter. They preferred a reference to a county court judge. They had no particular objection to an appeal to the Railway Commissioners, but thought it would lead to inconvenience and delay. They would have no objection to the appeal being made to the county court judge in the country and the Railway Commissioners in the London district, but in the case of an appeal being made from the country to the latter it was hard to bring the local authorities to London. There had been a few cases in which the Post Office had had to pay compensation for injuries by falling wires during construction, but there had been no compensation cases arising from the falling of wires which had been blown down by the wind.

Mr. J. S. FORBES was called, and, examined by the chairman, said that he was the deputy-chairman of the United Telephone Company. He said he had a great deal to do with the rights of the Post Office and telephone companies, having had litigation with them for a considerable time. They came to a compromise, and by an agreement the United Telephone Company became licensees of the Post Office. The development of telephonic communication had been impeded by the restrictions of the Post Office. Of course the Post Office had bought up at a very high price the telegraph companies, and they considered it their business to protect that business by every means possible. They foresaw that telephonic communication would interfere with their revenues, and telephone companies were tied up by restrictions, and at last the Postmaster-General agreed to give additional facilities to the telephone companies.

But, in spite of that, you have difficulties by reason of the want of legal status?—Yes, we are under great difficulty; in fact, we are only allowed to carry on our operations on sufferance, and that enormously cripples our operations and prevents us getting on as rapidly or effectually as the business requires. I doubt whether we are aware of the enormous extent to which this can be done, and the importance of it in a multiplicity of ways. For instance, one is with reference to fires. The diminution of fires has been traced to the extension of the telephone. I have a wire for my own use, fixed from Victoria Station to Beckenham Station. I live within three miles; there is no telegraphic communication, except from Bromley, and for that I am charged 1s. from London, and sometimes 2s., and sometimes 2s. 6d. for delivery. Well, I found that when I got my telephone to Beckenham a great many people wanted to make use of it. That sort of thing is growing, and there are thousands of merchants and clerks living at Ramsgate and Margate who would make use of the communication. I think that every railway station adjacent to a town ought to be connected with a telephone in the centre of the town. You cannot do that without a legal position, and certain facilities being assured to you outside the caprice of individuals or public bodies. I think that the time has come when the telephone, like other public enterprises of great moment, should have something like compulsory powers given to it having regard to certain interests.

There are other things, besides the difficulties of the Post Office, that you want removed, and the want of legal status. There is the nervousness of the public about overhead wires?—There are a great many people of that sort, and their nervousness is in proportion to their ignorance. There is a theoretical danger, but nothing to justify an impediment to a great public work. Cabs in London, and the parcels vans, and the butchers' carts are a source of danger; but still these things must be kept up.

The telephone cannot be continued beyond West Wickham and Edmonton because the local authorities won't allow wires to pass over their places?—Yes, there is a great deal of that sort of thing, and you are much at the caprice of individuals. We have 4,000 subscribers, and we have multifarious private wires. The question is, is it of sufficient public utility to justify its existence, and can it exist, or ought it to exist at the caprice of individuals? We do not think that it ought. We should therefore prefer to be under the Board of Works rather than under thirty-eight vestries. We should then have uniformity of treatment. The Board of Works would be the best authority for making bye-laws, and there should be an appeal on any matter of vital importance to some outside tribunal in case of serious difference. That appeal should be to a department of state, say the Board of Trade. The utility for a communication between the different railway companies that have their termini in London is very great. We cannot communicate by telegram, because it is too slow and does not answer our purpose. We do it by telephone, and the managers consult with each other as though they were in a room. It would be very useful in removing troops from Chatham or Dover to the north of England, and we could make our arrangements and come to conclusions as to what we were to do, passing the troops on from one company to another in a few minutes, just as though we were sitting in a room; in fact, the uses of the telephone in the future will be very great. There is no reason why every railway station half a mile or three-quarters of a mile distant from a town should not be connected with the centre of the town by telephone, and there are thousands of ways of utilising it at small cost. I use the telephone myself many times when I do not get time to use the telegraph. There are restrictions, owing to the state of the law and to the prejudice of individuals, which we want to remove.

In reply to Sir JAMES M'GAREL HOGG, the witness said that they would be sure to have uniformity of despatch if the controlling authority of the telephone companies was the Board of Works. The railway companies hold their rights from the Postmaster-General, and they are precluded from putting up wires, except with the consent of the Postmaster-General.

By Sir ALEXANDER GORDON: Do you seek the power merely to cross a man's field from two different posts, or do you seek to put a post on a ground or a house?—We should have compulsory power to do both and pay for any damage.

You do not recognise the right of appeal to the owner?—No.

If I have agricultural land, and you put the post in the middle of that field, do you claim the right to go on that crop whenever you think proper?—Yes, subject to payment for the damage.

Supposing I am an astronomer and I want to sweep the horizon with my telescope, what compensation will you give me?—I will put you in telephonic communication with Greenwich as compensation [laughter].

Is the feeling against wires the same as what you called a frivolous feeling against the ventilators?—It is about as sensible, but it is not so focussed.

By Mr. DICKSON: You think that the tenant should give permission to have the wire placed on his house?—Yes; that seems a sufficient protection to the landlord.

Are overhead wires necessary?—I have come to the conclusion that it is absolutely necessary to have overhead wires.

If overhead wires were not used, would it be possible commercially to develop the interest of the telephone?—No. Of course, the telephone costs £20 a year, and that is considered a very heavy payment for the convenience of some persons; but if that argument is to prevail and overhead wires are not to be used, it must cost more than at present.

Do you look forward to a reduction of the price?—I suppose in time, with simplicity of construction and efficiency, that would follow almost as a matter of consequence.

Ought you to have increased facilities for the erection of wires?—Yes; it is in consequence of the difficulties of way-leave that we have to make eighteen points of exchange where a much smaller number would suffice, and that means increased cost. Simplicity gives an efficiency of service, because every time you have a transfer there is a delay and irregularity.

It was said that between 100 and 200 wires were damaged in London in the late snowstorm. Is it your experience that the overhead wires are a source of danger?—You have wires falling, but I suppose the measure of danger is the loss to life or limb as the result, and these cases are marvellously few.

In answer to Mr. GRAY,

The witness said that the telephones would demand a night service, and they hoped to supply that.

By Mr. FIRTH: Are you anxious to have authority to place overhead and underground wires without consent of anybody?—No; I have said that I am willing to submit to an authority, such as the Board of Works.

You want to be enabled to carry your wires over anywhere without the consent of the owner?—Yes—the intervening ground between two necessary centres.

That is a power you have not now?—We are absolutely on sufferance.

Supposing you stretch a wire over a house, and there comes an exceptional snowstorm which causes the wire to break, would you be liable in damages to the person you injured, the snowstorm being possibly considered an "act of God"?—I have not had the advantage of being trained as a lawyer, or practised at the bar; but, still, I understand that an "act of God" would not generally be visited on an individual. If this telephone work is to go on there must be compulsion of a reasonable or rational kind, and that might be defined by the law.

Do you think that legislation should be enacted to give compulsory powers to telephone companies?—Yes. If this is to be a matter of public utility it should be carried out under reasonable conditions, and not be at the caprice of individuals.

By the CHAIRMAN: In case of danger to the occupying tenant would there be compensation to the landlord or to the tenant?—To the tenant if he were injured. I should not like to interfere with the common law. Those affected by the danger should receive the compensation. The going over premises as proposed by the Bill confers no right. The public utility of the telephone is so great that the companies will have to have compulsory powers sooner or later, and I think it would be the readiest and most economical way to recognise the necessities of compulsion which attach to it.

Mr. WINTERBOTHAM was the next witness. His firm were solicitors to the United Telephone Company, and he had personal charge of the evidence in this case. He understood the Telegraph Act of 1863 applied principally to the business of telegraph companies as then carried on. It then consisted of collection between town and town with one public office for the despatch of messages. The bulk of their work was therefore on railways

Digitized by Google

and public roads, and their run was longer than for telephonic communication. Therefore, the first thing was to obtain the consent of the railway authorities; and all the powers and regulations were for the purpose of protecting owners of property adjacent to or adjoining the roads in the case of the line running along these roads. There is a power under sec. 21 of the Telegraph Act, 1863, with reference to telegraph companies who pass over private property entirely. If they obtain the consent of the road authority, they may pass the wires over the property adjoining or near to the street, provided that it was not building land or a pleasure ground.

But you draw a distinction between the work that you describe and that of the telephone companies?—The Act hardly applies to the great bulk of telephone companies, whose principal business is to connect and exchange by a house-to-house line at some points not very far distant, going as nearly as possible as the crow flies. We do not use the streets in the ordinary sense of the term, and we have to get the wires over them. We do not use the streets in the way this Act contemplates their being used. Then our lines are being very constantly renewed and others taken away, and then lines are cut up. Assuming that we have got the attachments, our lines are connected very rapidly indeed, and any regulations, such as those provided by the Act of 1863, requiring a change in this would be quite inapplicable. When that Act came into operation it might take twelve months to run a line. First, the road authority's consent has to be obtained, and if they object they go to a County Court judge or a magistrate, from whom they appeal if necessary to the Railway Commissioners. But even assuming the consent of the road authority given, they have to publish notices, serve them upon the owners of property within fifty yards of the road, and advertise in the local papers, and wait twenty-one days for notice of objections, and refer these objections to the Board of Trade. The whole process is one which might be applicable on a traffic line of many miles in length but which would be altogether inapplicable to a short line over a house.

And such a system would be incompatible with the development of telephones?—Yes; we can hardly get on at all. In the country it takes us six or eight months or longer; in towns, when they obtain the consent of the road authority, they may run near the roads without further consent, but they have to give 21 days' notice, even in that case; and that seems to take a month before you can commence. The Post Office do as I do; they would get the necessary permission, and pass over people's houses without the 21 days' notice, and if objection is taken, they would arrange the matter, or try to arrange it, or get it round some other way.

On behalf of the telephone companies how would you sum up what you desire?—I agree with Mr. Forbes in saying that the business is a necessary one, and has become increasingly important, and that such facilities must be given as will enable us to connect subscribers by these wires as speedily as possible. What is necessary for that purpose is a matter on which there may be some difference of opinion, but we are quite agreed as to this—wherever we have permission to erect poles, we should have power to pass over intervening property without asking permission of the owner, subject to paying compensation, should any injury be done.

You limit the payment to injury; do you mean incidental or depreciation of property?—There was a case suggested of a person who wished to observe the stars. I could imagine the wires being thrown across would be a serious injury; but, except in such cases as that I cannot conceive of any injury being done by the passing of a wire over.

You would not pay for the compensation?—We should not pass within a certain distance from the roof, and if he requires it to be removed at any future time we should be bound to remove it, and we should obtain no easement or right by passing over. We should pay compensation if we did any injury—that would be sufficient to protect any public right.

If you paid anything at all in the recognition of right it would be a pepper-corn rent?—Such a recognition should be given, as it would give protection in every case.

You would pay for mere attachment where it was made?—Yes, I think that that ought to be properly made. I would claim the right of passing over property, and I would claim the right subject to restrictions and regulations similar to that of the Postmaster-General on passing along roads or under roads wherever it was feasible. Whether it would be necessary to ask for compulsory powers to make attachments, I am not clear. At the present time facilities have been granted readily in most cases, and the difficulty has chiefly arisen from the fact of passing over property. If we get permission from two persons to erect poles, we have to pass that wire over 100 people, and one of these objecting would prevent that wire passing.

Then you ought to have some compulsory power to override factitious opposition?—I think so. In regard to passing over a public road, any regulations for the purpose of preventing improper erections the telephone company would not only assent to but would be glad to see adopted.

Therefore, you would be liable to the regulations of some public body. Have you any choice of what that public body would be?—Of course, in most towns there is one municipal authority; in London it is not so, but we must have one body to look to in the metropolis instead of 38. The Metropolitan Board is the only general representative body at present. The Chelsea Vestry suggested that Board for this purpose. At any rate, it should be a representative body which should control us. Whatever body you have should control the whole of a town and the suburbs of that town. We want certainty and uniformity. Another point is despatch and rapidity—that is of the greatest importance.

Mr. FIRTH: Do you agree with the St. James's Vestry, that every wire should be registered?—I think that there would be a difficulty in keeping a registry of wires, but every pole is marked in such a way as to show what wires there are. I do not know how the wires could be registered unless they were marked. In practice it would be a little awkward. So far as getting a record of existing wires there would be no difficulty about it.

The Committee adjourned until Thursday, the 16th April.

COMPANIES' MEETINGS.

The Direct Spanish Telegraph Company (Limited).

The twenty-third ordinary general meeting of this Company was held last Monday, at the Cannon-street Hotel, Sir James Anderson in the chair.

Mr. CH. GERHARDI, the manager, read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: Before moving the adoption of the report I will, as usual, make such remarks as occur to me concerning matters that the shareholders ought to be cognisant of. The first remarks I will make will be rather against the Company perhaps, at all events they will show you the worst side; then afterwards I shall tell you what, in my opinion, are the prospects of the Company. I begin, then, by saying that since I became a Director of this Company we have found to our regret that the old cable is in such a bad condition that we cannot at present see how much it would take to put it in order or when it will be done. In the first place we have not money sufficient to spend upon any expensive inspection or overhauling of it. In the second place we have not at the present time a ship available. All the ships, owing to the present war, are taken up for telegraph purposes abroad, and nothing but a very expensive ship could now be had. For that reason we could very well afford to wait until another season, by which time I hope we shall have a larger revenue in hand, and one of the Eastern Company's ships will be able to effect the repair, at all events to effect the overhauling. Next, gentlemen, we have lost in our revenue considerably this year, owing to two causes; the first is that there has been cholera in the Mediterranean, which induced the Spaniards to put on quarantine at all the ports, and drive all the commercial men, who are our best customers, away from Marseilles and Barcelona. Next the land lines in Spain have been working very badly. Spain, I am sorry to say, has a deficit in its Budget to such an extent that they have been unable for the last two years to expend any money upon the repairs of telegraphs. The result is unfortunate to us, because the lines are so bad that telegrams are very slow either coming by this Company or by the Eastern Company. Now these are two causes of our present unfortunate position, but there is still another. Some few years ago we adopted what is called the word system, by which merchants can send one word to answer any purpose they think proper, and the Telegraph Conference of five years ago decreed that the public should have eight languages with which to form their codes, and make the words in those languages mean anything they like. At the same time the stipulation was that only words should be used which are common to the usage of those eight languages. Unfortunately there has arisen within the last year or two—especially the last twelve months—a number of enterprising gentlemen who manufacture the commercial codes, and they totally and entirely disregard the languages. They put odd syllables together and make such combinations as to lead us to a most disastrous result, the effect being we are carrying three messages just now for the price of two a year ago. These are the bad points, and I will now state what we are doing to overcome them. We are at this moment doing all we can at Madrid, with all the influence—diplomatic influence—that we can bring to bear upon the Spanish Administration to get the lines put in better order. I have had a long letter this morning—a telegram yesterday, and another on Saturday reporting progess—not so good on Saturday but better this morning, and I hope in the course of a little time—perhaps I should not say in the course of a little time—but in the course of some time we shall have the lines in Spain put in first class order. That alone will give us some increase of traffic. Then there is, as I daresay you all know from the papers, the commercial treaty just passed between Great Britain and Spain, which has long been in abeyance. That we think ought to make a large increase in our traffic. There has been a differential tariff against English trade for a considerable number of years; that is on the point of being removed. I think I read yesterday that it had passed the Cortes in Madrid. The next thing, gentlemen, is one which is the main reason for which I came on this Board, and it is the main reason for the Eastern Company having sought to get an interest in the affairs of this Company. Any one conversant with the map will see that the Eastern Telegraph Company have a land line through France, a land line through Italy, and through Austria, Germany, and Russia, and we have long thought it desirable that we should have one through Spain. Should we succeed in having a good line through Spain the same as we have through France, the Eastern Company then propose to take a new cable from Malta to Carthagena and Gibraltar, thus diverting a considerable amount of traffic to the Bilbao cable. We are trying with our agents in Madrid, and are backed up with the highest diplomatic influence in this country, to get that through line through Spain. It is the object with which the Eastern Company took an interest in this Company, and it is the sole reason for my being here. I hope to have a through line in connection with the Direct Spanish at Bilbao to work a large portion of the Eastern traffic. Now, that and the commercial treaty between Spain and this country should, I think, give a new phase to our traffic, and an improved condition of things. At all events, it is all that can be done. Then we have the Telegraph Conference coming off in August, by which the different telegraph administrations—by that I mean the Governments of Europe—will have their say about this abuse of code language, which is simply ruinous to commercial companies. I do not know that I have any other remarks to make. The accounts are simple, and any little increase or decrease here or there is not worth referring to, compared with the main object of getting this Company into a dividend paying state. Until our traffic increases, and until we get good lines in Spain, I do not see any specially encouraging features worth referring to. With these remarks, gentlemen, I beg to move "That the report and accounts now presented be, and they are hereby received

Digitized by Google

and adopted." Very likely some gentleman has some questions to ask, which I shall be very glad to answer if I can.

Mr. ETLINGER seconded the motion.

Mr. BIRKIN asked if one or two lines were in existence when the £10 preference shares were created.

The CHAIRMAN: Only one.

Mr. BIRKIN said that that being the case, upon what grounds did they suspend the payment of the dividend on the preference shares, seeing that there was only one line of cable in existence when the preference shares were issued, and according to the Directors' own report, the present line was in perfect order?

Mr. BEARD asked how much money had been spent over the old cable, and whether it would not be better to abandon it altogether. It seemed to be a halter round the company's neck, and to do a great deal of harm both to the preference and ordinary shareholders.

Mr. BAKER considered that the report was very unsatisfactory. On the 14th of January the news came upon himself and many of his fellow shareholders like a bomb that the dividend would not be paid on the preference shares, and the shares fell from 14 to 10. He thought the time had come when they should call up the remaining £1 a share on the ordinary shares to pay the cost of the repairs. If they were going to spend a lot of money on repairs, what was the use of having £13,000 uncalled? It seemed to him the time had arrived when it ought to be called up at once. He noticed on the register there was a large number of shares held by the Eastern Company, and possibly it was not in the interest of that Company that the call should be made; but the £1 call, with a portion of their reserve fund, would be ample to pay for any repairs that might be requisite, and then, instead of going on, as the Chairman had foreshadowed, with the expectation of getting a dividend in, perhaps, 10 years, they would be able to pay one at once on the preference shares. He suggested that the call should be made at once and spent on the overhauling of the old original cable of this Company.

Mr. COCHRANE thought they should be informed what was the amount of interest held by the Eastern Company. He also thought they should have the precise case on which the opinion of counsel had been obtained that they could not pay the dividend on the preference shares. The question of paying dividend when capital was not intact had come before other companies besides their own, and he thought it would be fair to the shareholders and Directors that they should be clearly informed as to the position in which this Company was placed. He was a holder of both classes of shares, but principally of the ordinary shares. Although he had asked this question, he did not look with great alarm at the non-payment of the dividend on the preference shares, because it was cumulative and would go on till such time as the Company was able to pay it, and the ordinary shareholders would not get a farthing. On a previous occasion the Board refused to hear criticism, and they were then assured by Mr. Neil Bannatyne that the course that was being adopted was one that was likely to bring them into smoother waters. He was afraid they had been listening too long to suave promises. He thought the Company had better be handed over bodily to the Eastern. There were two representatives of the Eastern Company on the Board, and possibly the interest of the Eastern was not compatible with that of this Company. He did not think that the majority of the Board should be representatives of the Eastern Company. He thought it would be desirable that some committee should be appointed to report as to the best mode of carrying on this Company.

The CHAIRMAN, in reply to the questions, said they had only one line to Bilbao, and that had never been a very good line. With regard to getting rid of the old cable, that might be brought before the shareholders at some future time, but he thought that first of all they ought to investigate it at two or three points and see if the whole of the cable was equally bad. It did not appear to have been a cable that was ever fit for the bottom on which it was laid. With regard to calling up the remaining £1 on the ordinary shares, they could not do that for the purposes of repairs. Besides, it would not bring in sufficient money, as he thought that anything short of £20,000 would be useless, even in making a trial. The Eastern Company held about £30,000 in ordinary shares, and were doing their best to obtain the line he had referred to. It would be no use for the Eastern Company to absorb the Direct Spanish, as another company would be formed at once. Whether he was re-elected or not, to him was a matter of perfect indifference. In the financial papers he was accused of being on too many Boards. He was willing to be on fewer. He was certain of this—it was immensely to the interest of the different telegraph companies that the Directors were the same persons, because if that were not the case the rivalry would be disastrous. It was by keeping together and knowing each other, and working amicably, that they were able to keep up a dividend somewhere. He thought they would very soon regret it if the present Directors were displaced, as it would break off a combination. The traffic of the Direct Spanish was far too small for the Company to stand alone or to fight. It would be very easy for the Eastern Company to find money enough to lay a cable to Spain in opposition to this Company, but they had never opposed any existing company, or entered into rivalry with any other company. For that reason they made a joint purse with the Direct Spanish years ago, and he did not think they would regret the connection between the Eastern. He thought he had explained all the points. There was nothing to hide and he had nothing to be afraid of.

The motion for the adoption of the report was then put and carried unanimously.

Mr. BAKER asked the solicitor's opinion as to the practicability of making the call of £1 a share on the ordinary shares.

The SOLICITOR replied that he had not considered the point, and could not give a reply without reading the prospectus.

Mr. BAKER thought they should make the call, as they were sadly in want of money.

The CHAIRMAN said it would not meet the case, as they could not use the money for the repair of the cable, and they only wanted money for that purpose.

Sir James Anderson and Mr. Etlinger, the retiring Directors, were then re-elected, and Mr. Herbert R. Duke, the retiring auditor, was re-appointed.

A vote of thanks to the Chairman and Directors then terminated the proceedings.

LEGAL.

Thornton v. The Electrical Power Storage Company (Limited).

In the High Court of Justice, Queen's Bench Division, on Monday last, before Mr. Justice Kay and a special jury, an action was brought by Mr Frederick Thornton, an electrical engineer, to recover damages from the defendant company for being dismissed from their service as works manager without notice or just cause. The defendants admitted that he was dismissed without notice, but denied that the dismissal was wrongful.

Mr. LOCKWOOD, Q.C., in opening the case for the plaintiff, said that Mr. Thornton became engaged by the defendant company to serve them in the capacity of works manager in the year 1882. Prior to that date he had been in the employment of Messrs. Latimer Clark, Muirhead and Co., and his attention was called to an advertisement which he saw in the *Engineer* of the 15th September, 1882, in the following terms:—"Wanted a thoroughly energetic man to conduct the entire management of large electrical works. One with a knowledge of French preferred. Salary £1,000 a year." The plaintiff accordingly made application for the appointment. At that time the chairman of the company was a Mr. Daniel Cooper, and a Mr. Volckmar the managing director, and the company was originally started for working the patents of the latter gentleman. After some interviews with the managing director, Mr. Thornton eventually received his appointment as works manager; but the salary was not £1,000 a year, as set out in the advertisement, it being arranged that he was to come for a probationary term of three months, his remuneration to be £500 for the first year, the engagement to last for three years, and the salary to be increased at the rate of £100. On the 30th September an interview took place between Mr. Volckmar, the plaintiff, and the then secretary of the company, when it was pointed out to him the kind of duties he would have to perform, and he was told that he would be the sole responsible person present at the works. On the 9th October, 1882, he entered upon his work, and all went on smoothly. In the early part of the year 1884 Mr. Volckmar, who was a gentleman who took a very prominent part in the management of the company, was engaged a good deal upon the Continent, and consequently was not able to devote so much time to its affairs as previously. Mr. Collett was therefore appointed to act as general manager, but he had no authority over Mr. Thornton at the works, and again everything went on in a satisfactory manner. One of the Directors of the Company was a gentleman of the name of Courtney. He had been a director at the time of the plaintiff's engagement, but was out of England, in America. After the resignation of Mr. Volckmar he took a very much more active part in the management of the company, and in fact from that time assumed the duties of managing director. Apparently Mr. Courtney did not entertain the same high opinion of the plaintiff as had been held of him by Mr. Volckmar, and in August, 1884, for the first time a disagreement took place between Mr. Thornton and the company, which, however, blew over. Shortly after that date a Mr. Drake, who appeared to have been a connection of Mr. Sellon's (another of the directors of the company), was appointed to the office of managing engineer. Mr. Drake's duties could of course in no way clash with those of Mr. Thornton, and nothing occurred to create suspicion in the mind of the plaintiff until the 6th of October, 1884, when a letter was received by him from the company to the following effect, viz., that, in accordance with his request and in view of the recent appointment of Mr. Drake as managing engineer, his duties should be defined clearly. In the first instance the writer thought it well to enclose a copy extract from Mr. Drake's agreement:—"The duties of the managing engineer were to well and faithfully carry out all the instructions given to him by the company or the managing director of the company. He was to be responsible for the quality of all articles manufactured by the company, and for those purposes to issue all orders to the works manager of their factories and staff . . . . as may seem advisable, and to supervise all installations. . . ." His (Mr. Thornton's) duties would therefore be of the usual kind appertaining to the post of works manager, and by his being constantly at the factory he would be able to give a rigid supervision to the manufacture of secondary batteries. Further details were to be settled at a conference. At the interview he was forbidden to correspond "direct" to parties as he had been in the habit of doing, and certain other of his duties curtailed. The plaintiff afterwards wrote further: "With reference to your letter of the 4th, I beg respectfully to inform you that the duties of the engineer conflict with those under my agreement for three years. . . . I mean to adhere to the terms of the agreement." On the 9th of October, before they could have received his letter, he got a memorandum instructing him to attend the Board meeting on that morning, and he accordingly went to the head offices for that purpose. Shortly after his arrival he was called in by the secretary (Mr. Dell), and informed by Mr. Courtney that he was summarily dismissed. The justification of the defendant company relied principally on the following pleas:—1st. That though he was on the 6th October told to write no letters excepting through head-quarters, he afterwards did correspond with the Swan and Edison Company "direct." 2nd.

Digitized by Google

That he gave an order for red lead after Mr. Courtney had told him he was not to do so any longer. 3rd. There were charges that he had not properly kept the books. With regard to that charge Mr. Thornton had not been able to have the books kept as he wished, owing to the fact that in consequence of the company not having been such a success as was anticipated, his clerical staff had been reduced to such an extent as to prevent it. After some trivial matters there was this suggestion, not made openly in the pleadings, viz., that he had received from persons with whom the company were dealing something in the nature of a commission, which suggestion would be denied by Mr. Thornton, and he would call in other persons to contradict it.

Mr. Frederick Thornton, the plaintiff, was then called and examined by Mr. Haigh. In the course of his evidence in chief, which bore out the the above opening statement, he positively denied having received any commission on any goods either bought or sold.

Witness was then cross-examined by Mr. Webster at considerable length as to the condition of the books. He stated that there was an old lead battery formerly belonging to the defendants. He had valued it in December, 1883, at £220. In July, 1884, he sold it to a Mr. Browne for £55. Mr. Browne carried on business in Wolston, and was a metal merchant. The battery consisted of 56 wooden boxes, lined with sheet lead, and filled with lead plates, one half positive and one half negative. His estimate of '83 was made up, as far as he could remember, as follows:—56 lead-lined boxes, at 30s. a piece, £84; 15 tons of lead plates, £9 a ton, £135; and 3cwt. of copper, at £2 a cwt., £16, making a total of £225. In the day book there was an entry "Old lead plates, terminals, &c., from the battery, as agreed, £55." He did not put down that it was the whole of the battery, because it was simply sold as old metal. In July, 1884, lead had dropped about £4 a cwt. He told Mr. Courtney that the battery had been sold some time at the end of July. Browne did some smelting at 30s. a ton, including carriage both ways. Did not know that Messrs. Eutolms did it cheaper. Had sold Browne some old copper wire at 30s. a cwt., and bought back old copper when cleaned at 70s. Could not have been used for their own purposes exactly as it was. Thought 30s. a cwt. a fair price considering the state it was in. He gave an order for ten tons of red lead, the value of which was about £14 a ton, but did not do so because he was unwilling that the order should go through the head office. It was wanted at the time. The works were in telephonic communication with the head office.

Mr. Arthur Browne, metal merchant, of Wolston, and two former *employés* of the defendant company, were then called, and the plaintiff's case concluded.

Mr. Webster then opened the defendants' case. He said that if the jury found the defendant company had been in the wrong they would then have to pay the plaintiff £700 for the year, reducible by what he had been earning since his dismissal, or was likely to earn, which would make it a sum of between £300 to £400. He had been struck by the point of the question which had been put to the plaintiff by the foreman of the jury as to whether he (the plaintiff) had to keep the books under his agreement. He did not complain and never had complained of the fact that particular entries were not made in a particular manner, for that he was not responsible; but he as works manager, like every works manager, had to direct what entries should be made as to matters which came under his superintendence, and in that respect he very grossly neglected his duties. Further, it was because he had simply grossly neglected his duties, quite apart from those of keeping the books, that he asked the jury to find that the company were justified in dismissing him. In the month of July some of the directors interviewed Mr. Thornton at the works, and told him that things were very unsatisfactory. He did not receive the communication as he ought to have done, and was very insolent; however, he afterwards apologised, and the matter blew over. But on the 6th of October the directors finding, as they had been finding for months past, that materials in vast quantities were being ordered at the works, and that they could get no account whatever—moreover, that the work turned out was out of all proportion—they determined to keep a check, and told the plaintiff that all orders were to be sent out through the head office. Notwithstanding that, on the 7th October, without the slightest communication with the head office, he ordered fourteen tons of red lead, of the value of about £130 or £140. That red lead was only delivered, it turned out, on the 22nd October, so that it was not urgently required, and the factory was in telephonic communication with the head office. The directors had the greatest difficulty in finding out how it was that their works were costing such an enormous sum to carry on. They had interviews with the plaintiff, who explained as best he could, but when they came to look at the books they found that from the beginning of the year 1884 no entry had been made of any sort of the cost of the batteries going out, or of the repairing those returned. The very first thing a works manager ought to be able to do was to give information as to what the manufacture of the goods was costing, and to show thereby whether his management were satisfactory or not. During the time of Mr. Thornton's management the cost of labour alone was 85 per cent., which, after his dismissal, was reduced to 45 per cent. Then what was the position of Mr. Browne? He would say a word or two as to that. Mr. Thornton at the end of 1883 valued the old works battery (it was in his own handwriting) at between £230 and £240. Mr. Sellon, who was no fool in these matters, would tell them that there was about 22 tons of lead in the old battery, that the plaintiff never said one single word as to that bargain, and that it passed out of the company's possession into Browne's for about £50, without an entry which they could trace, and, at Mr. Browne's own showing, he got about £150 for it. Then there was the copper wire which had been sold to Browne, and sold by Browne again to Messrs. Johnson and Matthie just as it was at a large profit. Mr. Sellon would tell the jury that it was perfectly untrue to say that it was unsuitable for their own use. That was not all. For a considerable time the company had been in the habit of getting their lead smelted at Messrs. Eutolms, and when Mr. Sellon was conversing with the plaintiff on the matter the latter mentioned the name of Browne. Mr. Sellon had never heard of it, and asked him why he had sent the stuff to Browne, and he told him that it was because his charges were much lower, which explanation perfectly satisfied Mr. Sellon; but on subsequent inquiry he found that the statement was simply an untruth. He asked the jury to defer their judgment until they had heard what the defendants had to say.

Mr. John Scudamore Sellon, examined by Mr. Moulton, said he was a director of the defendant company and a partner in the firm of Johnson, Matthie, and Co. As far as he could recollect he heard Browne's name mentioned in September, 1884. The dismantling of the old battery was determined on in accordance with the recommendation of Mr. Thornton. He asked the plaintiff in June, 1884, what it was worth, and he said between £200 and £300. Had not the slightest recollection of his ever telling him that it was worth about £80. Did not think it likely, as he knew the value too well. With regard to the smelting, Mr. Thornton told him that he had applied to Emptholden's and Lock, Lancaster, and Co., and their prices were too high. Thornton said Browne smelted lead on better terms than the well-known smelters. The proceeds given by Mr. Browne he should think were very much less than those given by the regular smelters. Browne's average return would be about 66 per cent. His returns should have been about 85 per cent. on the old plates. The lead linings in the boxes would yield more. The regular smelters' charge for conversion was about £1 a ton on what they took in. He calculated the loss on that particular transaction to the Company to be about £360, in comparison to what would have been obtained from one of the regular smelters. The quality of the cotton-covered copper wire was the best known. The cost of drawing it would be about 4s. to 5s. a cwt. Mr. Thornton had bought scrap copper from Browne at 70s. The copper wire would have been the very best thing possible for the purpose for which the scrap copper was required. He should consider 70s., the price given by Thornton to Browne for scrap copper very high. In July and August to September india rubber rings were purchased by Mr. Thornton at 5s. a pound; they ought to have been obtainable at 3s. a pound. They had done so since Mr. Thornton had left. Mr. Thornton had purchased at various times a considerable quantity, amounting to about 2,000 to 3,000 tons.

Cross-examined by Mr. Lockwood: He was also a member of the Anglo-American Brush Company, in which he took a great interest. Mr. Drake was formerly in the employ of that company. His calculations as to prices were based on the invoices. They ought to have been presented to the Board at their meetings. He could not say that they were not. It was the duty of two of the Directors to go through the invoices after the manager had ticked them. Colonel Stewart and Mr. Ladd were the two gentlemen. It was also their duty to call the attention of the Board to any excessive charges, &c. Did not know the battery was to be sold, or that it was ever brought before the Board. The company was formed for the purpose of working the patents of himself, Mr. Volckmar, and Mr. Swan. Mr. Volckmar and himself had differed as to the management of the company considerably. Mr. Courtney had agreed with him in most matters. Mr. Courtney was also a "Brush" director.

Mr. J. Irving Courtney said he was the managing director of the company. Was not a technical man; he was a barrister. The question of the sale of the battery was never brought before the Board. Mr. Thornton never complained to him that the clerical staff was insufficient for the keeping of the books. Once he had asked him to increase his staff for the purpose of taking stock, which he refused to do owing to the position of the company. Mr. Thornton offered the books for his inspection, but it was late, and he did not look at them.

Cross-examined: Remembered the Board being consulted as to the "breaking up" of the old battery.

Mr. F. Drake stated he was the managing engineer of the defendant company. Had seen some motors which had been sold by Mr. Thornton at £2 10s. each. They had since been priced at £5 5s. each. Considered too much had been given for the india rubber rings.

Cross-examined: No motors had been made since.

Mr. Justice Day: There is only a difference of 5s. in the two estimates.

Mr. Keen, chartered accountant, stated that he had examined the books of the company. The prime cost book had not been written up for the year 1884. They were not kept in such a way as to enable a person looking into them to get at the prices of various goods at once, without picking out the information from a number of books with a good deal of trouble.

Mr. Moulton and Mr. Lockwood then addressed the jury for their respective sides.

Mr. Justice Day, in the course of summing up the case, said there was no doubt that the plaintiff was dismissed one year before his time was up, and thereby he lost £700, but he had since, to his credit, been fortunate enough to obtain employment at a salary of £300 a year, and therefore the jury would have to take that into their consideration in fixing the amount of damages, should they be of opinion that the plaintiff was wrongfully dismissed. If they were of opinion that the plaintiff wilfully disobeyed the lawful orders given to him by his employers, the employers were then entitled to dismiss him; also, if his conduct as manager was not that which the defendants had a right to expect—that was to say, if he "substantially" neglected their interests. He used that word because it was not every act of negligence that would justify dismissal. Casual negligence would not justify a master in dismissing a servant; the law had to consider whether the servant had so misconducted himself as to render a continuance of the relations between master and servant unreasonable.

The jury retired to consider their verdict, and after a lapse of twenty minutes returned with a verdict for the plaintiff for £80.

Mr. Justice Day delivered judgment accordingly.

NOTES.

THE RISING IN COLUMBIA.—The telegraph between Aspinwall and Panama has been cut.

THE NEW FRENCH MINISTRY.—M. Sarrien has been appointed Minister of Posts and Telegraphs, in place of M. Cochery.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 3rd April amounted to £2,982.

THE WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ending 31st March amounted to £4,290.

THE ELECTRIC LIGHT IN BRUSSELS.—The lowest estimates for lighting the new Theatre Flamand in Brussels are:—Gas, £1,509; electricity, £1,846.

ELECTRICITY AND WARFARE.—Arrangements have been made at the Garrison Point Fort, Sheerness, for firing the 38-ton and 25-ton guns by electricity.

THE "GERMANIC."—During the recent gale in the Atlantic the electric light on board the ss. "Germanic" was extinguished in some parts of the vessel.

THE ELECTRIC LIGHT FOR BALLOONS.—A balloon ascent was recently made from Philadelphia, the aeronaut taking with him an electric light for use above the clouds at night.

ERRATUM.—In our issue of last week the paper of Mr. Preece was incorrectly described as being read at the Society of Telegraph Engineers. It was read before the Royal Society.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of March were £1,455, against £1,764 in the corretponding period of last year.

THE EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of March, 1885, amounted to £68,296, and to £67,285 in the corresponding period of 1884; increase, £1,011.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended the 31st March are £3,838, as compared with £3,543 in the corresponding period of 1884.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this company are as follow:—Receipts for March, £23,200; 1st January to 31st March, £64,400; corresponding months, 1884, £60,600; 1883, £57,200.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts for the week ending 3rd April were £2,394, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company, including Government subsidies, for the month of March, 1885, amounted to £46,193, and to £41,351 in the corresponding period of 1884; increase, £4,842.

CUBA SUBMARINE COMPANY.—The number of messages passing over the lines of this company during the month of March was 4,116, estimated to produce £3,500, against 3,852 messages, producing £3,296, in the corresponding month of last year. The traffic receipts for the month of December, estimated at £2,500, realised £2,553.

THE LIGHTING OF THE PADDINGTON STATION.—The arrangements for electrically lighting the general offices and hotel at Paddington Terminus, and the Royal Oak and Westbourne Park Stations of the Great Western Railway with incandescent lamps are approaching completion. It is expected that the work will be finished in about six weeks.

THE GINGERBREAD FAIR IN PARIS.—The correspondent of the *Daily Telegraph* says:—On Sunday night the fair was in full swing, and as the electric light beamed steadily down on the gaily-decorated booths, the bespangled and brawny *saltimbanques*, and the merry crowds of sightseers, the whole scene was interesting and picturesque to the highest degree.

AUSTRALIA.—An installation of the electric light has been successfully effected at the Eveleigh locomotive running sheds in Sydney. There are about 500 lamps in one bay of the shed, the light from each being reckoned to equal a 20-candle gas-burner. The Government of Tasmania intend laying a cable across the Derwent from Hobart to Bellerivie for the service of the battery on Kangaroo Point, and also the east coast districts.

THE EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY.—This Company notifies the interruption of the Zanzibar-Mozambique cable. Telegrams for places beyond Zanzibar will be sent on by a steamer which leaves Zanzibar for Mozambique on or about 25th instant. The company's repairing ship has been ordered to proceed to effect the necessary repairs. The manufacture of the duplicate cable to be laid between these points is well advanced.

COALING STATIONS AND THE TELEGRAPH.—Remarking upon England's naval defences in case of war, a Hong Kong telegram says:—"The public in the East demands the provision of torpedo fleets for all the coaling stations as an urgent measure of defence. The home yards could turn them out rapidly. A direct telegraph cable between Hong Kong and Singapore is also urgently required, the existing cables being in French and Russian hands."

PRODUCTION OF INDIA RUBBER IN BRAZIL.—The export of india rubber has increased rapidly in the past few years. From Pará and Manaos, the two principal ports in the Amazon Valley, the export during the five years from 1839-44 was 2,520,000 pounds, of the value of £79,000. In the five years 1854-1859 it had increased to 21,500,000 pounds, of the value of £800,000; and in the five years 1874-1879 to 66,000,000 pounds, of the value of £4,400,000. In 1882 the quantity exported was about 22,400,000 pounds.

THE ELECTRIC LIGHT IN ANTWERP.—The works at the central electric lighting station at Antwerp are being rapidly pushed forward, and it is hoped that everything will be in readiness by the opening of the Exhibition next month. The installation consists of 3,000 Siemens incandescent and 100 Gülcher arc lamps; four Naeyer generators of 150 horse-power each, two compound Cockerill engines of 400 horse-power, and four Gülcher dynamos, each giving, at a speed of 280 revolutions per minute, a current of 600 amperes and 65 volts.

THE ELECTRIC LIGHT IN VIENNA.—A valued correspondent, writing from Vienna, informs us that the Imperial Continental Gas Company have obtained the concessions for electrically lighting the Opera House and Burg Theatre, and are commencing work at once. The same company have the contract for the Bucharest Opera House, which is to be lighted on the Edison system in a few days, and have furthermore obtained a ten years' contract to light the New Royal Palace at Bucharest. The installations are going on well at Temesvar,

Digitized by Google

the life of the incandescent lamps averaging already about 1,800 hours.

TELEGRAPHIC COMMUNICATION WITH THE AFGHAN FRONTIER.—The *Daily Telegraph*, in a fourth edition, says:—We are able to state, from inquiry in the best informed quarters, that the gravity of the events already announced is not diminished by any particulars received at the Government departments. The explanation of the fact that the tidings have arrived from St. Petersburg, is that the wire by Meshed has been cut, consequently no telegrams have for some days reached the British Government. The Russian wire is continuous from St. Petersburg to Merv, and it is by this line that the intelligence has been brought.

MILLAR'S PATENT COVERED RIBBON WIRE.—Some of our correspondents are at a loss to understand the nature of Mr. Millar's patent, seeing that this class of wire has been manufactured by Messrs. W. T. Glover and Co., Messrs. Shaw, Connolly and Co., and other firms for many years past. We wrote our description from the samples forwarded to us by the patentees and manufacturers. They appear to us to bear a close resemblance to the anti-capillary wound wires shown to us by Messrs. Shaw and Connolly, being covered with a double strand of cotton wound in opposite directions, but for further particulars of the patent we must refer our correspondents to the manufacturers themselves.

ELECTRIC JEWELS.—The electric light has been introduced with extremely pretty effect in the pantomime at the Theatre Royal, Belfast. Miss A. Glover, who sustains the part of Electra, carries four lamps throughout the performance, whilst in the transformation scene thirty additional lamps are employed as head-dresses. The current is supplied by small accumulators, manufactured specially for the occasion by the Belfast Electric Appliances Company, who have charge of the installation, while the lamps used are Swan and Edison 4-volt, which are both reliable and economical for this purpose. We believe that this is the first time that as many as four lamps have been effectually run off one battery during a whole pantomime.

ELECTRIC LIGHTING FOR STEAMSHIPS.—The new Wilson liner, "Eldorado," which was launched from Earle's Shipbuilding and Engineering Company's yard on the 2nd inst., will be lighted throughout by electricity. The Anglo-American Brush Electric Light Corporation have received, from the Admiralty, instructions to supply at once two of their special slow speed Victoria dynamos, coupled to Brotherhood engines, to H.M.S. "Active" and "Shah" at Portsmouth Dockyard. The Union Company of New Zealand's steamer, which is now being constructed at the yard of Messrs. Denny Brothers, Dumbarton, will be furnished with a dynamo and engine capable of supplying the current to 300 twenty candle-power incandescent lamps. The dynamo, which is a very powerful one for its size, is being manufactured by the Anglo-American Brush Electric Light Corporation.

THE DANGER OF OVERHEAD WIRES.—One of the dangers of overhead wires has recently been illustrated in Chicago. A large fire occurred at the Langham Hotel in that city on the evening of the 23rd ultimo. Upon the roof of the hotel there had been placed a large structure by the telephone company, to which a goodly number of wires were attached. All who have handled aërial wires know the immense tension that is sustained by these frames, which are balanced by diametrically opposed forces, so that in a normal condition the strain is *nil*. In the case mentioned the wires leading in one direction were destroyed and disconnected by the heat, and the strain, coming upon the wall of the structure, pulled a section of it over, with the unfortunate result of burying nearly the whole of the fire patrol crew, who were at work, two of whom were killed and others badly injured.

THE ELECTRIC LIGHT AND WEATHER VANES.—We are informed that an enterprising firm of brewers at Vauxhall are about to erect an immense weather vane in the shape of a bottle, 20ft. long and 6ft. diameter, on the summit of their premises. It is proposed to light each end of the bottle with a powerful arc light of 2,000 candles—the one showing red, the other white rays, so that the direction of the wind may be ascertainable by night as well as by day. Such a mass, though built as lightly as possible, requires some skill to arrange for a free movement on its centre. Therefore, it has a stem of about 14ft., accurately and well fitted inside a tower, the top support being on rollers, while the base rests in a glycerine bath. The function of the latter is to ease the weight, which is 3½ tons, from its roller bearings. The idea is a novel one, and illustrates another of the many uses to which the electric light readily and effectively lends itself.

PORTABLE ELECTRIC SAFETY LAMP COMPANY. — This company proposes to adopt and carry into effect an agreement dated December 30, 1884, and made between Ernest Moreton, of 25, St. Margaret's-road, Brockley, Kent, of the one part, and Richard Shirling Ingall, of Palace-chambers, Westminster, as the representative of the company, of the other part, for the purchase by the company from Ernest Moreton of the letters patent, No. 7,439, dated 15th December, 1884, relating to certain inventions for electric lighting, and also any other electrical inventions of M. Gustave Trouvé, of 11, Rue Vivienne, Paris. It was registered on the 20th ult., with a capital of £100,000, in £5 shares. The purchase consideration is £70,000, £33,000 thereof being payable in fully-paid shares. The number of directors is not to be less than three, nor more than seven; the first directors to be appointed by the subscribers; qualification 100 shares, remuneration £1,000 per annum.

OUR TELEGRAPHIC COMMUNICATION WITH INDIA.—It is possible that our position in regard to telegraphic communication with India in the event of our engaging in a war with Russia is not generally understood by the British public. It is a significant fact, and an ominous one, that English telegrams cannot be transmitted to the East without passing through, if not a foreign administration, at least a foreign country. By the lines of the Eastern Telegraph Company the route is Vigo, Caminha, and Lisbon, thence to Gibraltar, Malta, Egypt (both by the desert line and cable through the Suez Canal), and Aden; with an alternative route from London, *viâ* Marseilles, to Gibraltar, and from Bona to Malta. The lines of other companies pass through Continental countries and Russian territory. Should the necessity arise, the cables to Vigo and Lisbon could be joined through direct to Gibraltar and Malta, leaving only the Egyptian route to be guarded.

THE COST OF GAS VERSUS ELECTRICITY.—Although our electric lighting companies, says the *Pall Mall Gazette*, have not yet managed to distribute much in the way of dividends, they have the continual assurance that they are on the right track to earn them. The substantial half-yearly dividends declared by our great gas companies and the price of their stock evidence the profitable nature of the business. But New York—Edison notwithstanding—is *par excellence* the great profit-yielding city for gas. A special gas committee has been looking into the details of the business, and it finds that for the past ten years a profit of over 4s. per 1,000 feet has been made, or, in other words, two-thirds of the cost of gas to the

Digitized by Google

consumer has been clear gain to the makers. Out of this it is computed that the gas companies have extorted from New Yorkers from six to eight millions sterling in ten years more than they were reasonably entitled to. No wonder there is ominous talk of imposing legislative control.

RECKENZAUN'S ELECTRIC TRAMCAR IN BERLIN.—We learn from the *Berliner Börsen Courir* that Herr E. A. Plewe, well known in Germany for the active part he took in organising the Berlin tramways, and also for being the sole *concessionnaire* of the Brush electric light system in Germany, is about to introduce Reckenzaun's electric tramcars in Berlin. Herr Plewe has recently visited England, and inspected the experimental car now running on the South London line, and having also received a favourable report on the system by Herr Zacharias, the engineer to the Berlin Electric Light Company, has ordered from the Electric Power and Storage Company the first of a set of motors, with gear and accumulators, intended for use on the line leading from the centre of Berlin to the Ausstellungspark, where a Japanese exhibition is shortly to be held. The line is 4½ miles long, and the cars are intended to perform twice the double journey, in all about 17 miles, with one charge. The accumulators will be charged from the electric light plant already existing at the exhibition.

THE BERLIN TELEGRAPHIC CONFERENCE.—The Victorian Government have been advised that the conference will take place on August 10. Amongst other things affecting the Colonies, the conference will be asked to consider the request of the recent Australasian Postal Conference, that a reduction might be made in the rates charged for press messages on Indian lines. It appears from communications which passed on this subject that there was no disinclination on the part of the Indian Government to meet the wishes of the Australian Conference, and no objection was raised by the telegraph companies interested, but Germany, as one of the Administrations interested in the telegraphic route to India, objected to any considerable reduction in the rates charged. As already stated, Mr. Murray Smith has been appointed to represent the colony at the conference, but, in the event of his inability to attend, the services of Mr. Cashel-Hoey, the secretary to the Agent-General, or Mr. Cameron Corbett, one of the Board of Advice to the Agent-General, will be sought.—*Colonies and India.*

LIGHTHOUSES AND THE TELEGRAPH.—A correspondent of *The Times*, recommending the connection of Eddystone Lighthouse with Plymouth by telegraph cable, writes as follows:—"All the arguments that have, in a measure successfully, been advanced to secure such communication between certain lightships and the shore apply with increased force to the Eddystone Lighthouse and Plymouth. We have recently had exemplified near Suakin the danger of the want of a ready means of ascertaining the approach or movements of an enemy. Major Templer's balloon now supplies the want. As the balloon is to General Graham's force so is the Eddystone to Plymouth. Plymouth is also an important mail packet station. The mail and other steamers from the East will shortly be bringing to the port many of our brave warriors in various stages of disease and bodily injury, whose friends, hitherto strangers to the port, will await with much anxiety tidings of the vessel's arrival. With the suggested telegraphic communication, under ordinary circumstances, some two hours' warning could be given in Plymouth, affording to anxious friends at any hour of the twenty-four ample time to get on board the steam tenders that communicate with incoming vessels. The advantage to our mercantile marine of such cable communication is so obvious that I need not occupy your valuable space by dwelling upon it at length."

A CORRUPTED METER.—Some amusement has been afforded the New York newspapers, says our American contemporary, the *Electrical World*, by the refusal of an electric light customer here to pay his bill, on the ground that he had not used any lamps. The Edison meter showed, or was said to show, that he had taken so much current, and he was therefore charged such and such a sum for it. It would be interesting to know if the particular electric meter which made a false charge of $9.29 had ever been associated with a gas meter. If it had spent any time in a cellar in the society of a gas meter it was quite possible that it was corrupted by the vicious influence and degrading example of the latter. That the gas meter does exert a most demoralising influence upon those who associate with it is sufficiently proved by the character of the managers of gas companies, not one of whom declines to profit by the false testimony of meters. Persons using the electric light cannot be too careful to remove their gas meters from the cellar before introducing the electric meter. The probability is that the electric meter is honest when left to itself, but that it is weak and easily led away by bad companions. If, on the other hand, it should turn out that the electric meter is as inherently vicious as the gas meter, the electric light will become as unpopular as gaslight, and the public will burn nothing but oil and candles.

A DIFFUSION PHOTOMETER.—M. A. Crova has designed a photometer for measuring luminous sources of high intensity. It is based upon the principle that when a translucent screen is placed in a uniformly illuminated field, in a direction normal to the incident rays, each point of the screen may be regarded as a luminous source and transmits light, the intensity of which depends upon the nature of the translucent material, in accordance with a law which also varies with the material, but in every case the rays diffused in a direction closely approaching the normal are equal in intensity. If there is placed behind the diffuser an opaque screen with an opening, the size of which can be varied at will, the intensity of the light normally emitted by this opening is proportional to the intensity of the luminous field on which the diffuser is placed, to a coefficient which depends on the nature of the translucent substance, and to the area of the opening, and varies inversely with the square of the distance. M. Crova employs a Foucaults photomometer, one half of the screen being illuminated by a standard light of one Carcel lamp placed at the end of a blackened tube one metre in length, whilst the other half is illuminated by the light to be examined. The latter passes down a tube which is movable on a graduated circle fixed at right angles to the axis of the first tube. At the further end of this tube there is a rectangular opening, the breadth of which remains constant, whilst the length can be varied by means of a micrometer screw. This opening is placed against the diffuser, and the size of the opening is altered until the two halves of the screen of the photometer are equally illuminated. For intensities up to 400 carcels the diffuser is made of ground glass, whilst for higher intensities opal glass is used.

THE ELECTRIC LIGHT AT THE GENERAL POST OFFICE, GLASGOW.—The Postmaster-General has entered into a new contract with Messrs. Muir and Mavor, of 140, Douglas-street, Glasgow, for electrically lighting the General Post Office buildings in that city. The installation at present consists of about 460 glow and 10 arc lamps. The currents are produced for the glow lamps from two 14-unit Crompton compound dynamos, while those for the arc lights are derived from three 4-unit Bürgin dynamos. The driving power consists of a pair of horizontal engines by Messrs. Marshall, of Gainsborough,

Digitized by Google

each indicating 40 horse-power, steam being supplied at 80lb. pressure from two multitubular boilers by the same makers. The engines are connected with the driving shaft by means of double-friction clutch gear, which enables the engines to be interchanged or worked simultaneously without any interruption to the light. The dynamos are driven through Hoyt's short-lap leather belting, which was supplied by Messrs. Balderston and Co., of Glasgow. An ingenious arrangement is provided for each of the spare dynamos. This is a centrifugal friction clutch, consisting of a loose pulley with two radial arms, keyed on to the shaft, and pivoted to a boss. When the machine is required these arms are released by the withdrawal of a wedge, and the centrifugal force presses the leather shoes on their outer ends against the inside rim of the loose pulley and sets the machine in motion. Should one of the working machines become disabled, a spare one could thus be substituted in a few seconds. The whole of the post office is served by two circuits, one for the arc and the other for the glow lamps. The arc lamp machines are so arranged that the extinction of any group or groups of lamps does not affect the remainder. The glow lamp machines are arranged to work in parallel circuits by a board specially designed by Messrs. Muir and Mavor, which provides against the reversal of the current in one machine by the other. The test of the capabilities of the electric light in the post office is a severe one, as, of course, it is necessary that it should be not only reliable, but constantly available and steady. During the winter months the greater portion of the lights have frequently been required to run for 100 hours consecutively, and in every respect the working is stated to be satisfactory.

THE TELEGRAPHIC SIGNAL.—There is an interesting little story in *Scribner's Monthly*:—"John Mills, the hero of the sketch, was a railroad engineer, and had been for a long time in the company's employ. When the new engine '59' was completed and placed on the road John was given charge of it, and he evinced a natural pride in his preferment. At one of the stations there was a young girl, a telegraph operator, between whom and the engineer there had sprung up a mutual attachment, and whenever '59' came along Kate generally managed to be at the door and exchange signals with her lover. One day the train was detained at the station, and the locomotive detached and sent up the road to do some additional work, and Kate went along for a ride. As she listened to the sharp, shrill notes of the whistle, it occurred to her that she might teach John to sound her name in the Morse telegraphic characters, so that she could distinguish his signal from that of the other engines, whenever his train approached. The plan worked to a charm, and far and near the whistle shrieked K-a-t-e, until one day, as the operator stepped upon the platform, she overheard a conversation between two young men, and learned that they understood the signal, and were laughingly wondering who *Kate* could be. Their means of communication having been discovered, they were obliged to discontinue it. In the meantime, Kate had, by means of the telegraph, made the acquaintance of a young lady, an operator in a distant city, but whom she had never seen, and to her she made known the fact that the secret had been discovered. Then her friend suggested a plan as brilliant as it was ingenious. It was simply to arrange a means of telegraphic communication between the approaching train and the station, so as to ring a bell hidden away in the closet in Kate's office, engine '59' being the only one provided with the means of completing the circuit, which was done by laying the poker upon the tender-brake so as to touch the wire in passing. Kate found an opportunity to acquaint John with the proposed plan, and in the meantime had found an abandoned wire which ran for a long distance close beside the track, and which she proposed to use for carrying out her purpose. Thanksgiving Day came soon after, and John fortunately having a holiday, he and Kate went bravely to work, and before the day had ended the task was completed, and proved a complete success. The finale of their love episode is as dramatic as their telegraph line, was ingenious; the latter not only does all that is expected of it, but is the means of preventing a collision, and, eventually, of obtaining for John and his scientific *fiancée* much emolument and consequent happiness."

THE NATIONAL TELEPHONE COMPANY IN ARBROATH.—This company some time ago intimated their intention of introducing their system into Arbroath, and also to connect it with Dundee on the west, Montrose on the east, and also Brechin, Forfar, and Kirriemuir. Since then their workmen have been setting up poles all over the town, chiefly on the tops of houses, and latterly they have been stretching wires to houses and offices, also fitting up the apparatus for the use of subscribers. On the 2nd inst. a number of gentlemen met in the Central Office of the company in Millgate, where they were welcomed by several Dundee gentlemen and directors. Mr. Bennett, general manager, and Mr. Miller, district manager, were also present, the latter conducting a series of interesting experiments, during which conversation was kept up with Dundee, Perth, Newport, and Broughty Ferry, all of which were satisfactory. A Dundee gentleman favoured the company with a song, a tune on the violin, and he also put the wires in contact with a musical box and a clock, the ticking of which latter was distinctly heard. Mr. Miller mentioned that the length of the wire between Dundee and Arbroath was 19 miles; that the number of poles erected was 350, averaging in length from 22ft. to 70ft.; and that the wire used was No. 2 galvanised iron. He also said that in Dundee the company had nearly 700 subscribers, and that in Perth they had other 120. In the Dundee district the average number of connections per day was just now 6,928, or upwards of 41,000 per week; and as each connection involved a question and reply, the number of messages sent by telephone per week was about 83,000. Mr. Bennett, during the course of the proceedings, remarked that the spirit of extension which was now characterising the Dundee district was going on in almost every other district of importance, and one of the latest proposals was to join Scotland and Ireland for the purpose of enabling their Glasgow subscribers to speak to their customers in Belfast. They were about to open an exchange in Stirling, and a connection would be established between that and Perth, which, when completed, would enable subscribers in Perth, Dundee, and Arbroath to speak to Glasgow and Greenock and all the other towns round about. Their programme also included Brechin, Kirriemuir, and Montrose, but they would have to see their way clear before making the necessary outlay in that direction, as they had great demands upon their capital and enterprise in the English and more opulent Scotch districts. They would, however, in time reach Montrose, and then they would press north to Aberdeen; and the end would be that all towns in the kingdom would be able to speak with one another.

ELECTRO-DEPOSITING VATS IN SERIES.—In an interesting paper, read before the American Institute of Electrical Engineers, Mr. H. B. Slater gave the following description of the apparatus employed by him in practice:—Connected with a vat containing 200 gallons of metallic solution was a small dynamo machine. The dimensions of the vat were—length,

Digitized by Google

6ft. 6in.; width, 2ft. 6in.; depth, 2ft. In it were three rows of nine anodes each, each anode being 8in. by 12in. One row extended from end to end of the vat at equal distances from the sides. The other two rows hung close to the sides of the vat, only one side of each of the side rows being exposed directly to the work. There were two spaces for work, one on each side of the middle row of anodes. The anode surface was $6+6=12$ square feet, and on the other two only one side of each row $6+6=12$ square feet, giving a total of 24 square feet. The distance between the plates or anodes on each side of the anode row was 15in. The vat, with both rows of work filled up, held just 20 pieces, 10 on each rod. The articles to be plated were hung with their flat sides to the anodes, and as they were about 1in. thick the distance between anode and cathode was 7in. The resistance of the vat was ·242 ohm between the terminals while full of work with the current passing. This included of course the $-e$. The E.M.F. of the dynamo = 12·32 volts after running 3 hours, and the resistance = ·2 ohm. The resistance of the connections was practically *nil*. By Ohm's formula we have $C=\frac{E}{R}=27{\cdot}87$ amperes. As the maximum current obtained was with an external resistance equal to the internal resistance of the dynamo there was very little waste of power. On receiving orders to increase the output of work, it became necessary to increase the facilities for doing it, and an exactly similar outfit was placed side by side with the first one, including both vat and dynamo. In each of the vats was placed another row of anodes, and so arranged that there were three spaces for work instead of two, as before. This increased the anode surface by one-half the original amount, viz., from 24ft. to 36ft., and as this increased the cross-section of the circuit in each vat by one-third, it of course produced a corresponding decrease of resistance. But by inserting this row of anodes the width of the vat was divided by 3 instead of by 2 as before. Originally the distance apart of the anodes was $\frac{30}{2}''=15''$, now it was $\frac{30}{3}''=10''$. The simplest calculation will show that these changes had reduced the resistance of each vat to less than 50 per cent. of its original value. One of the dynamos was now dispensed with, and the two vats connected in "series" to the other dynamo. The vats are side by side, two feet apart, and the dynamo is placed between them at the end, connected by a short, thick wire from the + terminal to one of the vats, and by a similar wire from the vat on the other side of it to the − terminal. The dimensions were now as follow:—The E.M.F. and internal resistance were assumed to be as before, 12·32 volts, and ·2 of an ohm. The external resistance between the terminals of the "series" was now, however, ·2018 ohm, or a total of ·4018. By Ohm's law $C=\frac{12{\cdot}32}{{\cdot}4018}=30{\cdot}7$ amperes. By the series arrangement nearly 31 amperes of current passed through each vat, and a total effect of 61·4 amperes, compared with 27·87 amperes from the same machine through a single vat.

INTERESTING LIGHTHOUSE EXPERIMENTS.—The important experiments at the South Foreland Lighthouse Station, under the direction of a Special Committee of the Trinity House, have been brought to a close. An official inspection was recently made of the three experimental towers, and the plant and apparatus, for the purpose of determining what should be retained for future investigations. The investigations of the past year have been specially directed to the subject of the contested superiority of the three illuminants, gas, oil, and electricity. The three experimental lighthouses were adapted specially for the contest of electricity, gas, and paraffin oil for the supremacy. They were fitted respectively with new electrical apparatus, with Mr. Wigham's gas apparatus, and the six-wick oil burners in extensive use in the Trinity Lighthouse service. The electric light was furnished by three powerful arc lamps supplied with current by three Meritens electro-magnetic machines, each arc being of about 12,000 candle-power. These lamps were disposed in the lantern of the lighthouse in triform arrangement, superposed one above the other, and could be used separately or in groups. The Wigham burners, first used in these South Foreland experiments, were provided with 88 jets. Subsequently burners with 108 jets have been employed under a quadriform arrangement of four such burners superposed. Such burners in the photometric room have given an illuminating value of 2,400 candles; but in the experimental lighthouse they have not developed quite so much light. The Trinity Service six-wick burners have been employed for oil illumination; the candle-power of each burner being 800 candles; the diameter of the flame, 4½in., and the superposition of the lights in the lantern being triform in arrangement. Sufficient general information as to the observations of the lights is current to enable some interesting conclusions to be deduced, and not the least interesting or important is the established fact of the superiority of the illumination of the electric arc for penetration of the atmosphere in foggy or hazy weather. In dense fogs on the Foreland, the electric rays became visible at distances varying from 1,900 to 1,500ft. The oil and the gas have been detected together at from 1,500 to 1,250ft. The high temperatures caused by the combustion of such furnaces of gas in the lantern are a serious detriment. With the original 88-jet burners the temperature rose during the exhibition of the light to 200 degrees of Fahrenheit; but the use of four 108-jet burners has elevated it to from 300 to 350 degrees. At sea, the electric light is in the ascendant; it has been ascertained that, with the three illuminants shown as single lights, the rays of the oil and the gas were lost at eight miles, whilst the range of the electric was maintained up to 14 miles. With the lights all at full power under their respective combinations the gas and the oil were lost at ten miles, whilst the electric was a good light at 14½ miles, beyond which it was not pursued. The additional electric machines have been maintained by the engines and plant put down 14 years ago for the permanent electric lighting of the Upper and Lower South Foreland Lighthouses. The dynamos used in the experimental lighting have each five sets of 12 compound magnets, placed radially, making a total of 60, and there are 24 induction coils on each of the five revolving armatures connected in parallel circuit. According to the measurements taken, the current given off at the terminals, with 600 revolutions, the lamp being placed in the machine room, is 218 amperes, and the electromotive force 35 volts, the light generated giving 19,000 candle-power by photometric determination; the power absorbed being 13·5 horse-power. In regard to the ranges of the gas and oil lights in the series of experiments just concluded, it is desirable to point out that the lenses employed in Mr. Wigham's gas lighthouse were four of a vertical height of 4ft. 1in. In the oil lighthouse the lenses employed were three of 6ft. 6in. each. The total height of the gas optical arrangement was 18ft.; the total height of the oil optical arrangement was 21ft. It may thus be seen why the ranges of these two illuminants should have been so near alike, as the beams corresponded to the respective vertical heights. With the electric light, as employed with the current of two machines sent through one arc, the optical apparatus was a single lens of 2ft. 9in. in height. The most important result in the whole series of experiments is the demonstration that the intensity of the electric light is superior in penetration of fog, mist, or rain to the larger superficial volume of combustion illuminants.

RESEARCHES ON GAULARD AND GIBBS SECONDARY GENERATORS.

BY PROFESSOR FERRARIS.

Under the title "Ricerche Teoriche e Sperimentali sul Generatore Secondario Gaulard e Gibbs," the well-known Italian scientist, Professor Galileo Ferraris, has just published a reprint of a paper submitted in January last to the Academy of Sciences of Turin. The care and diligence bestowed by the author on this important and much debated subject are evidenced by the fact that his theoretical investigation and records of experiments fill not less than 73 large quarto pages. As is indicated by the title, the work is divided into two parts, the first theoretical, the second experimental, and it is satisfactory to find that the latter is a complete verification of the former. We cannot enter at length into the formulæ established by the author, which enable him to calculate this most important of disputed values, the efficiency, with an approximation of less than 1 per cent. to the real value; but we may briefly indicate the method of treating the question mathematically. He begins by considering the simplest possible case, where the primary and secondary coils are exactly alike, and have therefore the same coefficient of self-induction and of induction on each other: call this coefficient b. The coefficient of induction between the iron core and either of the coils we shall call a. It is further assumed that the iron core is sufficiently sub-divided to preclude the possibility of any internal currents, and that its total mass is sufficiently large to prevent any approach to saturation. Under these circumstances its magnetism at any instant is proportionate to the sum of the primary and secondary current flowing at that instant. It will be seen from this that the author tacitly assumes that there is no hanging back or sluggishness in the iron when changing its magnetism, an assumption which seems plausible enough when we consider that the core is composed of a bundle of wires. Let ϵ be the electromotive force of the alternating current dynamo, a periodic function of the time t; let r and c be resistance and current in the primary circuit, and r' and c' the same values for the secondary circuit; let, further, m be the magnetism of the core given by the formula

$$m = \mathrm{M}\,(c + c'),$$

where M is a constant of the apparatus; then we have the following fundamental equations:—

$$r\,c = \epsilon - a\frac{dm}{dt} - b\left(\frac{dc}{dt} + \frac{dc'}{dt}\right)$$

$$r'c' = -a\frac{dm}{dt} - b\left(\frac{dc}{dt} + \frac{dc'}{dt}\right)$$

With the Siemens machine used, the electromotive force ϵ at any instant, t, can be expressed as a function of the form $\mathrm{E}\sin\frac{2\pi}{\mathrm{T}}t$, where T is the period of a complete alternation [that is the time elapsed between two consecutive changes of sign], and E the maximum electromotive force.

From these equations the author calculates the currents in the primary and secondary coils and the magnetism in the core for special cases.

If $r' = 0$—that is, if the secondary coil is short circuited, and if its own resistance, ρ', is negligible—he finds $c = \frac{\epsilon}{r}$ and $c = -c'$.

In this case the primary current circulates as if the secondary generator did not exist, and the secondary current is at all times equal and of opposite sign to the primary current. As a consequence of this $m = 0$, which means that the core does not become magnetised. In this case there is no retardation of phase between the primary current and the electromotive force which creates it, but if the resistance in the secondary circuit be gradually increased a retardation sets in, whilst at the same time the primary current decreases. If the resistance of the secondary circuit is infinite the retardation reaches its maximum value, viz., a quarter of the periodic time of the machine, and the magnetism of the core assumes the maximum value $\mathrm{M}c$. For intermediate values of r' the retardation and the magnetism have smaller values, and useful work is done in the secondary circuit. The energy absorbed in the primary circuit is in both extreme cases ($r' = 0$ and $r' = \infty$),

$$q = \frac{\mathrm{C}^2}{2}\rho,$$

C being the maximum of the primary current, or crest of the wave, and ρ the resistance of the primary coil. For intermediate values of r' the energy absorbed in the primary coil is greater. That developed in the secondary coil can be expressed by the formula

$$q' = \frac{\mathrm{C}'^2}{2}r',$$

and hence the coefficient of internal efficiency is

$$\mu = \frac{q'}{q} = \frac{r'\mathrm{G}^2}{\rho r'^2 + (r' + \rho)\mathrm{G}^2}$$

where G is a value depending on the construction of the apparatus and on the speed of the dynamo

$$\mathrm{G} = (a\,\mathrm{M} + \mathrm{C})\frac{2\pi}{\mathrm{T}}.$$

It is evident that since $\mu = 0$, for $r' = 0$, and for $r' = \infty$, there must exist a value for r' for which μ is a maximum, and this is $r' = \mathrm{G}$.

It is interesting to note that the resistance in the secondary circuit, for which the efficiency of the generator becomes a maximum, is independent of the resistance of the secondary coil. The external or commercial efficiency is somewhat smaller than μ, on account of the energy absorbed by the resistance of the secondary coil. The relation between the total and external energy in the secondary circuit is evidently

$$\frac{q''}{q'} = \frac{r' - \rho'}{r'},$$

and the commercial efficiency of the secondary generator is

$$\zeta = \frac{q''}{q}.$$

It becomes a maximum for a certain value of r', which is, however, not the same as before, but somewhat larger. If the primary and secondary coil are exactly alike $\rho = \rho'$, and the maximum commercial efficiency is very nearly

$$\zeta\ \mathrm{max.} = \frac{\mathrm{G}}{\mathrm{G} + 2\rho\sqrt{2}}.$$

It will be evident that this value is the nearer to unity the greater G and the smaller ρ. The latter condition is self evident, as it simply means that the electrical resistance of the apparatus should be low; the former condition means that a, M, and C should be large and T small; or, in other words, there should be plenty of iron, and of the softest quality, in the core, the self-induction and the mutual induction of the coils should be large and the periodic time of the dynamo should be small, so that there may be a large number of alternations per second. As a matter of fact the inventors employ machines of short periodic time, the number of alternations lying between 260 and 300 per second.

An important question in the practical application of the secondary generator is that as to the maximum output obtainable. It is not sufficient to know that at one particular value of the resistance in the secondary circuit the apparatus should give a high commercial efficiency, we must also know whether it will be practicable to work it at that efficiency and yet obtain a reasonable output. To investigate this question the author introduces the conception of equivalent resistances, which, substituted for the secondary generator, would absorb the same energy as that transformed in the primary coil.

The resistance is equivalent to the total energy in the secondary coil divided by one half of the square of the

Digitized by Google

maximum value C of the primary current, and for this the author finds the expression

$$\frac{q'}{\frac{1}{2}C^2} = \frac{G^2}{r' + \frac{G^2}{r'}},$$

which evidently becomes a maximum for $r' = G$. This is the same condition as was found for the maximum of internal efficiency, and the secondary generator has therefore this valuable quality (generally not shared by other electrical apparatus) that it gives a maximum of output when it is worked under conditions which make its internal efficiency a maximum.

The author next considers the question as to the energy computed when substituting an equivalent resistance for the secondary generator and its relation to the energy actually consumed when the generator is at work. The latter is always somewhat less than the former, and measurements taken without reference to this error make the apparatus appear less efficient than it really is. The author refers particularly to the tests made by Dr. Hopkinson and by M. Uzel, and finds that if μ' be the coefficient of efficiency found by these experimenters the real coefficient μ is given by the formula

$$\mu = \frac{\mu'}{\sqrt{1 - \left(\frac{r'}{G}\mu'\right)^2}}$$

The measurements objected to by the author were taken with a dynamometer and an electrometer, the indication of both being simply multiplied to obtain the electrical energy. This is a mistake, as no account is taken of the difference in phase between the primary current and the electromotive force at the terminals of the primary coil. In fact, if the secondary circuit be broken hardly any energy is absorbed in the primary coil, and yet current and electromotive force have considerable values. To avoid falling into the same error, the author has made all his measurements by a calorimeter, which is free from the objections which must be urged against the use of both the dynamometer and the electrometer. To the difference in the method of experimenting he attributes the fact that he found a maximum of internal efficiency when the resistance of the secondary circuit was about equal to G, whilst Hopkinson and Uzel found it for a much smaller value.

It remains to find the value of G. This is done experimentally by substituting for the secondary generator a resistance r_1, so chosen that the potential at the terminals of this resistance and the current are the same as in the primary coil if the secondary circuit is open. In this case there is no objection to the use of an electrometer and a dynamometer, because only comparative measurements are taken. As a result of his theory the author finds that in this case

$$G^2 = r_1^2 - \rho^2$$

and thus the determination of G is reduced to a simple measurement of the resistances r_1 and ρ.

For want of space we must abstain from reproducing the diagram showing the author's arrangement in his laboratory, which was connected with the dynamo by a circuit of about 600 yards total length, nor can we enter into a description of the ingenious methods by which he eliminated as much as possible any sources of error, or, when that was not quite possible, calculated the probable error. For these matters and for a complete table of the results we must refer our readers to Professor Ferraris' paper. We may, however, briefly record a few of the results. The secondary generator tested was one designed for the transformation of an electrical energy of 1·8 horse-power, and its particulars are given in Table A.

The core consisted of a central cylinder of wood, with a covering of straight iron wires to the thickness of about $\frac{5}{32}$in.

The primary current was 12 amperes.

Table B gives a few of the values obtained for the internal efficiency μ and the external or commercial efficiency ζ found by the formula, and ζ' found by experiment, with a varying resistance r' in the secondary circuit.

TABLE A.

External diameter of copper discs forming the primary and secondary coils, and placed over the core in alternating order	4·5 in.
Internal diameter	2·12 in.
Number of discs in primary coil	455
Number of discs in secondary coil	455
Thickness of discs	10 mils.
Weight of copper	40 lbs.
Weight of the whole apparatus	45 lbs.
Resistance of primary coil	·276 ohm.
Resistance of secondary coil	·285 ohm.

TABLE B.

r'	μ	ζ	ζ'
·28	·500	·000	·00
2	·876	·753	·74
4	·933	·867	·86
6	·956	·911	·90
10	·967	·940	·93
16	·974	·957	·95
22	·976	·963	·95
26	·975	·964	·95
32	·974	·966	·96
36	·973	·965	·95
40	·971	·964	·95

The author found by the use of the equivalent resistance that $G^2 = 500$, and we should therefore expect the maximum of internal efficiency if the resistance in the secondary circuit is $r' = \sqrt{500} = 22{\cdot}36$. This is verified by the experiment, as will be seen from the table given. The maximum of commercial efficiency occurs for $r' = 32$, which is also in accordance with theory.

The figures given by Professor Ferraris are so extraordinarily good that were it not for the high standing of this scientist we should hesitate to accept them as accurate. But with all the precautions adopted in the tests there is hardly room for doubt as to the value of the final results, and with so little loss in the secondary generator there is every reason to hope that, as far as alternating currents are concerned, the question of distributing electrical energy over a large area from a central station has here found a satisfactory solution.

Before concluding this notice on the work of Professor Ferraris we must briefly refer to his calculation of the "activity," or, as he calls it, the power of the secondary generators. The apparatus experimented on was capable of giving out 2·12 horse-power electrical energy with a resistance of about 22 ohms in the secondary circuit. It would then absorb about 2¼ horse-power in the primary coil. With any other resistance in the secondary circuit the power given out, and therefore the commercial value of the apparatus, would be less. Thus, for instance, at $r' = 10$ ohms (the resistance hitherto employed in the secondary circuit) it would only give out 1·58 horse-power, whilst 1·70 horse-power would be absorbed in the primary coil. The resistance in the secondary circuit was fixed so low on account of the result of the tests made by Dr. Hopkinson and M. Uzel, who found that the term $\frac{c'v'}{cv}$, which they erroneously took to be the efficiency, would be a maximum if the resistance of the secondary circuit were between 5 and 6 ohms. Professor Ferraris's recent investigation, however, shows that this term is not the efficiency, and that the most favourable resistance is from three to four times as great.

The author considers a core consisting partly of wood inferior to one consisting wholly of iron, and he finds that a similar apparatus to the one he tested, but without wood in the core, would give a maximum of output equal to 2·51 horse-power instead of 2·12 given by his apparatus. He concludes, therefore, that the introduction of a wood centre is a decided disadvantage.

NEW ORLEANS EXHIBITION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I read in your issue of the 21st ult. an interesting notice of the New Orleans Exhibition, but one which I fear may unintentionally convey an erroneous impression of the nature and extent of the Edison Company's exhibit there.

During my recent visit to America I went to New Orleans, just before the opening of the Exhibition, and although it was even at the opening notoriously incomplete, I was enabled to see sufficient to give me an idea of the vast undertaking and to repay me for the tedious journey south.

The Exhibition buildings cover more area than any other hitherto erected, and, as may be supposed, the artificial lighting of them formed a very important feature. It was originally suggested to illuminate a large portion by gas; but owing, I believe, to the city gas works not being large enough for such an increased demand, this idea was very properly rejected, and contracts ultimately made with various electric lighting companies for the work.

The contract for the whole of the incandescent electric lighting of the building was made with the Edison Isolated Company of New York, who during the last year have so successfully lighted the Exhibitions at St. Louis and Louisville, each with about 4,500 lamps.

At New Orleans the capacity of the Edison installation is 6,000 lights, although only 5,000 are used. There is also another large plant located just by the Exhibition for lighting the Government buildings.

The installation for the Exhibition building is by far the largest isolated plant yet installed, and is exceeded only by the Edison Central Station system in New York.

Those of your readers conversant with very large installations can readily understand the magnitude of the task of properly wiring for such a number of lights, and I may add that, although only a temporary exhibition plant, the wiring is carried out with almost the same careful attention to details as if it were for permanent use.

The arrangement of the machinery is worthy of special note. Six Armington and Sims high speed engines are used for driving the dynamos, and the foundation for the whole is certainly unique. Owing to the peculiar condition of alluvial soil and the proximity of water to the surface, the customary brick and stone foundations are dispensed with, and a huge system of timber work in the form of a gigantic wheel is framed and bolted together and set directly on the floor of the machinery hall.

The six spokes of the wheel are square timbers bolted together one for each engine, and near the rim of the wheel are square timbers for the dynamos. The engines are so placed that they radiate from a common centre—the hub of the wheel—which sustains the thrust of the six engines, and in the hub the chief engineer stands overlooking and controlling the whole apparatus with his assistants. The spot is termed "Fort Edison," owing to its resemblance to some modern batteries.

I give a detailed description of it, as it is the first instance I have seen of any artistic grouping of engines and dynamos, as usually they are not at all pretty in appearance, being spread all over the floor with but little attempt at arrangement.

A considerable portion of my time while in America I spent in noting what improvements and developments had recently taken place in electric lighting, as it is natural to expect great advances in a country so proverbially progressive. It is difficult in so extensive a field to form other than very general conclusions, but it is certainly my opinion that incandescent is largely replacing arc lighting.

This is not only the case in shops, but also in the large mills, factories, and railway stations, &c., which we have frequently been told could only be satisfactorily illuminated by the arc. I will not take up your valuable space by discussing the question at any length, but I am of opinion that the present Exhibition at New Orleans will afford a further triumph to the incandescent lamp at the expense of its rival.

A large proportion of the favour shown the incandescent lamp in America is undoubtedly due to the present capable and energetic administration of the Edison Company, who are fast distancing all their competitors. The quality of the Edison lamp, high from the first, has been still further improved, and the life of the lamp has very materially increased. No less than 2,000 lamps per diem are now being manufactured in the American works alone, and it is estimated that 150,000 Edison lamps are at present in use.

Rough and ready work of a cheap nature was long ago proved to be a mistake in America, and although due importance must be given to using the most efficient material, a thoroughly successful installation requires careful and competent labour, with ingenuity of arrangement. All these matters have not only been preached but thoroughly well practised, and it is to the good results accruing therefrom that we must look for the real reason of the great and marked advancement of the electric lighting industry in America, rather than to any natural tendency of the American to rush after anything new.—Yours, &c., JNO. B. VERITY.

King-street, Covent Garden, April 7th, 1885.

BLACKPOOL ELECTRIC TRAMWAY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been called to a letter in your last issue, signed "W. S. H."

If your correspondent wished to assist me in my work, don't you think the simplest way would have been to have seen me when he was in Blackpool? He might easily have done so by making inquiries, and would have learned that sumpholes are provided for. If he were a careful reader of your valuable paper he would have seen them therein described eighteen months ago.

I shall be only too pleased to receive suggestions from any one, but should much prefer receiving them direct, when if they are new I will publicly acknowledge them, and if already worked out the writer will be saved from publishing the incompleteness of his information.—Yours, &c.,

Blackpool. M. HOLROYD SMITH.

THE INVENTORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I find in an article, "The Inventions Exhibition, Electric Lighting Arrangements," you have a mistake, which if you will correct in next week's *Electrician* you will greatly oblige.

Instead of Old London, *Mackie* lamps, it should have been *Lea* lamps. They are the same lamps that were in Old London last year and in the United States Court at the Fisheries.—Yours, &c., JOHN LEA.

75, Arlington-road, Camden Town, March 30, 1885.

DOMESTIC ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Allow me, through your widely circulating columns, to emit an idea which, simple and of the easiest application, may prove, though in a matter of minor importance, a useful addition to the ordinary appliances for household electric lighting.

One of the very numerous advantages of electric lighting for domestic purposes is the fact of the light being produced by turning the commutator, dispensing thereby with matches and lighters of all kinds. This advantage is, however, reduced to a minimum by the necessity of using a portable light of some kind in entering a dark room, so as to lay one's hand on the commutator.

It has not, as far as I am aware, occurred to any constructor to use Balmain's luminous paint in the construction of commutators for household fittings. I need not describe any special disposition, and it is evident that the cost would be but small, while the benefit resulting from such a disposition would be considerable, as all who are accustomed to the use of luminous match-boxes for the night table are aware that it is at all times easy, small as is the emitted light, to lay the hand on the box in the dark.—Yours, &c.,

Brussels, April 29, 1885. G. MONTEFIORE LEVI, C.E.

THE LIFE AND CANDLE-POWER OF INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read many of the interesting letters and papers which have appeared since I ventured to question the accuracy of certain figures furnished by M. Foussat (see *Electrician*, pp. 246 and 294), but I am still of opinion that the method adopted in the preparation of them may have been similar to that of the learned Doctor Ananias, a notice of whose "Prolonged Experiments with Mr. Edison's Lamps" was given in *Zeitschrift für Electrotechnik* and in one or two of our English journals last summer, a few days before I first called attention to the subject.

He found that an Edison 16 candle-power lamp lasted exactly 1,000 hours if kept at its normal candle-power, and that the life of a 10 candle-power lamp under the same conditions was also 1,000 hours exactly. He made a careful record of the lives of lamps when burning at various powers above and below their normal 16 and 10 candles, and when the account of his investigations was published I plotted out the figures on a diagram, thus obtaining a very regular hyperbolic curve which suited *both* sets of lives, it being only necessary to use a horizontal scale of ¼in. per candle in the case of the 16 candle-power lamps, and a centimetre scale for 10 candle-power lamps.

I believe I am correct in stating that the results of extensive experiments carried out in this country do not agree with the reports received from abroad.—Yours, &c.,

W. H. MASSEY.

Twyford, Berks, April 6, 1885.

ON A PECULIAR BEHAVIOUR OF GLOW LAMPS WHEN RAISED TO HIGH INCANDESCENCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Perhaps you will allow me to make a few remarks on the observations of Mr. Preece regarding the above subject.

The blue glow observed between the platinum supports of the filament when raised to high incandescence and the diffused glow that pervades the whole globe are, I think, greatly due to the quality of the carbon filament and the degree of vacuum obtained, and not only to the high incandescence of the lamp. If the vacuum is of such a degree as to be of very great resistance between the platinum supports of the filament, so as to lessen the possibility of a shunt across *a e* or *a c* in Fig. 1 of Mr. Preece's article, and the carbon filament is sufficiently hard and has not been previously heated in a hydrocarbon gas, the diffused blue effects can be entirely overcome, even if the nominal candle-power be raised seven-fold.

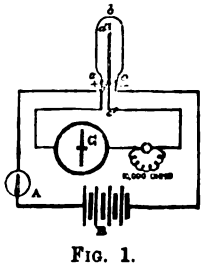

FIG. 1.

To show that the diffused blue effects between the platinum supports of the filament or the blue glow that pervades the whole globe when raised to a high degree of incandescence can be gradually lessened and entirely overcome, suppose a lamp is exhausted to a certain degree and raised to a high temperature, the blue effects mentioned above will appear. By continuing the exhaustion while the current is still passing through the filament the blue effects will become intermittent, until at length they entirely disappear. By further increasing the incandescence the blue effects will reappear for a short time, and at length they will again become intermittent, and again disappear as before. If the exhaustion be continued for some minutes, and the lamp hermetically sealed, it may then be raised to the highest incandescence without any blue effects being observable. Also, these effects may be produced by an alternating current as well as by a direct one. Neither is it necessary to have the distance between the electrodes increased any further than is required for what are now known as low resistance lamps in order to prevent an arc forming across the terminals, as lamps are now made requiring 150 to 200 volts in which the distance between the terminals is not greater than in 45-volt lamps.

Probably the time is not far distant when lamps which are at present reckoned as *high resistance* will be reckoned as *low resistance* lamps.—Yours, &c.,

JOHN B. DUNCAN.

Alexandra Electric Light Works,
Gateshead-on-Tyne, April 4, 1885.

MULTIPLE WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having frequently been taken to task by friends on the subject of multiple wires for parallel arc lighting, I have made the following notes, which may interest some of your readers:—

1. With a required difference of potential at the terminals of the lamp there must be a considerably greater difference of potential at the terminals of the dynamo, which must also be constant.

2. That this excess of E.M.F. over that required in the arc must be absorbed in independent resistances inserted with the arc in each derived circuit, and not in a common resistance as in incandescent lighting. For let the figures 1 and 2 represent the two methods of connection, and let

$V - V_2$ = the difference of potential at the terminals of the dynamo,

$V_1 - V_2$ = the difference of potential at the terminals of the lamps,

r = resistance inserted with each arc,

c = current in one lamp,

n = number of lamps parallel,

$R = \frac{r}{n}$.

C = total current from dynamo which is practically constant.

Then in Fig. 1,

$V - V_2 = (V_1 - V_2) + C R$ = constant,

* C R is also practically constant;

$\therefore\ V_1 - V_2$ = constant,

and $c \propto$ the conductivity of the arc.

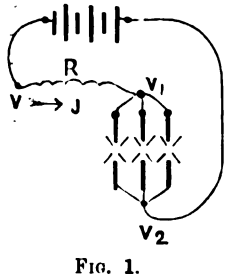

FIG. 1.

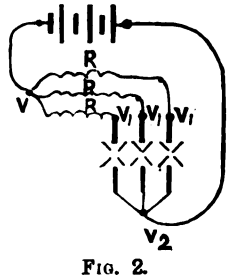

FIG. 2.

But the conductivity of the arc $\propto$ (or any way increases with) the current, and these two functions both varying together, any change in the arc is aggravated to the utmost; it is also curious to note that this change will eventually take the direction of excessive current. For suppose the conductivity of the arc to decrease, the current will go on falling until it is insufficient to support the carbon rod against the action of gravity, and the arc will then be shortened, and the opposite condition will set in, finally short-circuiting the lamp to a great extent.

In Fig. 2, on the other hand, $V_1 - V_2 = (V - V_2) - cr$; therefore, if c is increased, $V_1 - V_2$ is decreased and tends to reduce c; and *vice versâ*, if c is decreased, $V_1 - V_2$ is increased and tends to augment c. It appears, therefore, that separate circuits are advisable for this system of arc lighting, the resistance of each of which must be equal and sufficient to act as a current regulator to the lamp.—Yours, &c.,

GUY C. FRICKER.

7, Charlwood-road, Putney,
April 1st, 1885.

* It must be noticed that the variation in c may cause only an insignificant variation in C, until the whole system has broken down, so to speak, and degenerated into a general short circuit.

CONDENSERS.

We invite those of our readers who are Electricians and who have Condensers in their charge to kindly furnish us with information as to the actual capacity of such Condensers as against the nominal value; together with a note of the temperature readings with both wet and dry bulbs; and any other data which may be of interest.

NATURAL GROWTH.

People not accustomed to the dilatory ways of the "leading journal" were, no doubt, surprised a few days ago to see in its columns a long reprint of the Committee's Report on the Electric Lighting Act—or rather its recommendations for the amendment of that Act by a new one—at least a month after the document had been made public. The Committee's previous Report was similarly delayed. Possibly *The Times* may think there is no hurry; and in this we are inclined to agree with it; for as there seems to be no immediate disposition to consider the Committee's proposals favourably, and still less likelihood of Parliament devoting to them any attention whatever during the present Session, there is little need for hurry. The Committee lost no time in drawing up its programme, and discharged its duty thoroughly, besides showing that it knew exactly what it wanted, and was not afraid to ask for it. With equal promptitude the organs of the Government informed the electric lighting interests that if that was what they demanded they certainly would not get it. There is no inclination, we should imagine, on the part of the Committee to abate one jot of its just and reasonable pretensions; and so there the matter for the present ends.

On the whole we are not sorry to see this renewal of what has been called the "dead-lock." It has lasted a good while already, with results perhaps salutary to those who are responsible for the original Act; certainly it is, in our judgment, favourable to the permanent interests of electric light undertakers. Acts of Parliament there have been before now which have proved to be inoperative; they die, and are buried in oblivion; but this one is not so much the dead lion in the path as a live jackass, which sooner or later will be pushed aside by the pressure of public opinion. Time will show whether this or any other animal of the kind, duly disciplined, will be needed for the progressive locomotion of electric lighting industry; but in its present attitude the creature is a manifest obstruction, and useless for any active purposes whatever.

Meanwhile the natural growth of the electric light is advancing in the way we have always desired it should, and almost with as much rapidity as we had hoped it might. Every week our columns notify its experimental or permanent installation in fresh and unlooked-for places; and so far as we can discover there is no falling off in its popularity, or failure in its operations, except such as may be attributed either to incompetence or inexperience. These are faults which time will soon mend, every mishap with installations on a small scale furnishing useful lessons for the larger ones when their turn comes. This is how every new industry ought to grow; and fortunately the Act does not interpose any serious obstacles to natural development in the early stages of electric lighting.

Two examples of the kind we allude to are furnished in our columns this week. One is the arrangements, which are nearly completed, for lighting the general offices and hotel of the Paddington terminus, as well as the Royal Oak and Westbourne Park stations of the Great Western Railway. The installation is spoken of as the largest of the kind yet undertaken in this country. Be this as it may the auspices under which it will be carried out augur well for its success, there being no stint either of means or talent to carry it out successfully.

The other is of a somewhat different character, and is even more encouraging. After a two years' trial of the electric light in the General Post Office at Glasgow, the Department has entered into a contract of a more permanent and extended character. The success of this experiment so far is decisive as to the suitability of the electric light under most severe conditions, the lights having to be not only perfectly steady and trustworthy but always available. During the winter months, it is stated, the greater portion of the lights have frequently been required for as long a period as one hundred hours consecutively. In every respect the illumination and the general working have given great satisfaction, as is proved by the circumstance that the Postmaster-General has entered into a fresh contract for a longer period, and on terms which are no more experimental but commercial. Moreover, the Post Office has acquired all the lamps and fittings within the buildings as its own property, the engines and generating plant being located in premises belonging to the contractor in the rear of the Post Office. We understand that the contract is based on a fixed charge per month, which is the most rational arrangement for such installations when, as in this case, the average consumption has been approximately ascertained.

In this manner lighting by electricity may reckon to win its way in public favour; and, although the process may appear to be slow, it is sure, and as fast as under present conditions it is desirable to travel. When the Electric Lighting Act comes on again for consideration, as in due time it certainly must, the undertakers will not be so much at the mercy of the Board of Trade as they were three years ago. They can no longer be twitted with not being in possession of data on which a regulat-

Digitized by Google

ing Act ought to be framed, or of being ignorant of the means of ascertaining the value of the commodity they wished to supply. They are entitled to the same terms as those enjoyed by the water and gas companies, subject only to such restrictions as experience has proved to be expedient for them; and by working and waiting patiently they will, we believe, get nothing less than these terms.

ELECTRICAL CONDITION v. RADIANT HEAT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: For reasons with which I have duly furnished you, my knowledge of dynamic electricity does not enable me to follow your intelligent correspondent "T" in his description of the stages of progress in that branch of science, as given in your last number under "The Wimshurst Electrical Influence Machine, &c." Until, therefore, I shall be in a position to have access to dynamos, batteries, and all their appliances, I must keep within the sphere in which I am supplied with facts, the *rationale* of which comes within my comprehension.

At page 402, under "Physical Society," March 14, Professor Guthrie, president, in the chair, you have given a paper read by Captain Abny, "On Recent Researches on Radiation," in which it is said that a hot body loses heat in three ways—by conduction, by convection, and by radiation. Now, one of the results of the inquiry referred to in my letter in your journal of the 14th was that if air were introduced into a vessel containing dead vegetable matter, such as dead moist leaves, the air did not undergo decomposition, but the leaves decomposed and formed carbonic acid, the hydrogen being evolved as a carbonate. That is decomposition *per se*. But if oxygen and nitrogen were introduced, the oxygen rapidly combined with the carbon, thereby demonstrating that air is a chemical compound, and that under decay the affinity of oxygen for carbon is much greater than for hydrogen, which was invariably evolved as a light carbonate—in fact, the fire damp of coal mines. But if a little organic matter were introduced into the vessel, as in putrefaction, the affinity of the oxygen was the same; but the hydrogen compounds were various, such as sulphurets, phosphurets, ammonia, &c.

If, however, a piece of bread, as in the process of making toast, be held in front of a *radiating* or bright fire the affinities are reversed, and the oxygen, instead of combining with the carbon, goes exclusively to the hydrogen, the carbon remaining intact; and if a piece of paper be placed on the bars of a grate under wood, as in the ordinary process of lighting a fire, the carbon of the paper not only remains intact, but the letter press may often be made out. So that under decay and putrefaction, with electrically negative conditions, the affinity is with carbon, whilst under positive conditions it is with hydrogen to the deposition of the carbon, as in the formation of smoke, soot, and lampblack.

Now, if a nail-rod, or a small round bar of iron of which nails are made, be put into an ordinary fire, it may be raised to cherry-red heat, and when taken out, if placed in front of the nozzle of a smith's pair of bellows, the cold air, or, more properly, compressed air, will raise it to the welding heat. So that in the compressed air and the incandescent or radiating fire there is the same influence, the only difference being that in the cold compressed air, which, as I have already said, will freeze meat in Australia and keep it in a frozen state while coming to us, that influence is greater than it is with the incandescence of combustion. What, then, may be the nature of the *radiation* from a fire or from a piece of iron raised to a red heat, I must obviously leave to the decision of rational minds, or to those that are to be influenced by matter-of-fact evidence. And, clearly if "radiation" from an ordinary fire be purely electrical, there can be no radiation of heat from an electric lamp, or what is called "incandescent"—as if all lamps or their lights were not incandescent.

It is said, "in the case of the carbon filaments of an incandescent lamp the loss of heat by conduction is insignificant" (of course there can be no heat to lose), "and a series of experiments has been made to determine the amount of radiation; that is, the energy expended as radiant heat for every unit of electrical energy expended in the lamp." What can "energy" (of quite recent introduction into science) have to do with heat or with electricity? "Mr. Crookes has investigated the subject of radiation in high vacua, the cooling bodies being thermometer bulbs, and has come to the conclusion that at pressures between forty millionths and one millionth of an atmosphere, the radiation varies as the mean molecular free path."

How there can be "pressures" at an inconceivable fraction of atmosphere to me is quite incomprehensible; but in this latter part of the paper there is a fact recorded that evidently has escaped the notice of the captain and of Mr. Crookes, and that is that in high vacua there is a cooling influence, an influence which I suspect will be found to keep pace with the rate of exhaustion. I have said that electricity is the cause of cohesion, and Professor Tyndall has demonstrated that, if two planes be placed on one another in the air pump, on the receiver being exhausted the planes firmly adhere, but lose the cohesion on the air being introduced. Another fact, but the authority for which I do not at present recollect, is that if a lump of ice be put into a flask, and the flask be exhausted, the flask on being put over the flame of a spirit lamp may be made red hot, but the ice melteth not; on all which facts I think I may repeat what I have already suggested in the M.S. of "Electrical Condition," whether a vacuum be not a representation of space, or those regions in which the planets revolve round the sun. Our luminary being a highly heated or negative body, must necessarily be surrounded by an atmosphere electrical in proportion to his negative state.

My idea of the sun is that he is composed of non-luminous gases infinitely more dense than anything we are acquainted with, and which gases undergo no change, so that there is no waste. But science is constantly speculating on the amount of heat radiated by the sun, and how that loss of heat is restored. In a recent lecture delivered by Dr. Tyndall at the Society of Arts, after telling his audience what arrangements he made at Hind Head to determine the amount of radiation of heat from this planet into space, and that on a frosty night he warmed up two thermometers, and suspended one to a line and placed the other on cotton wool, and that the one on the cotton wool coated much faster than did the suspended one, he stated that the cause of the difference was owing to the cotton wool being one of the best of radiators and a bad conductor of heat, so that the thermometer could not recover from the soil the heat it lost by radiation; whereas I contend that this radiation of heat exists only in science, and that the cause of the difference was that the thermometer on the cotton wool was horizontal to space, which, under a clear sky, is constantly pouring down electricity, whilst the one suspended was vertical.

On the evidence of facts, however, it is possible that when the radiation distance was considered, there should have been conditions that no longer prevail. My father frequently observed to me when I was a lad that he could not think why it was that, whilst a shower of rain plummed the earth so, watering from a watering pot made it as hard as a brickbat. And had my father lived to the present time he might with equal reason express his surprise that, although at the period referred to, snakes, frogs, and toads—in fact, all the reptiles—swarmed, and ague prostrated whole families at a time, both the reptiles and complaints had disappeared from the locality he then resided in. The word plum is or was a common word in the West of England, signifying soft or spongy, the more especially in reference to the soil, and the why a shower then actually raised it was that the earth—that is, the crust of the earth—being then positive, the electricity brought down by a shower, as it still is, was actually repelled, and was most gratefully received by the atmosphere, which was then negative, the cooling influence on a summer day being most delightful. But now that the conditions are reversed, and the earth is negative, it not only gratefully receives and retains the electricity of rain, but also demands at least twice the quantity of manure it formerly did to make it fruitful.

Digitized by Google

When in my tenth year—that is, in the winter of the short Peace of 1814–15, I was sent to Nantes with my mother, sisters and brother, and being half way between Nantes and the coast when the Battle of Waterloo was fought, it was determined that we should remain at St. Malo or St. Servan, as being more convenient for my father to come to us occasionally. At that time our garden walls swarmed with the small grey lizard, whilst the small green frog was equally numerous; so plentiful was fruit of all kinds that it was left to rot on the trees. But when I took my family to St. Brieux in 1855, during a residence of seven years I saw but one snake and one green frog, a few frogs and toads, but the small grey lizard had totally disappeared. As to the fruit, the peaches, for example, were ten sous or five pence each, of not one-third the size of those that were sold in about 1820 at 6d. the hundred. In fact, there were no buyers.

Shortly after my return to England in 1822, like most other young men, I paid little or no attention to such matters, but in 1845, having then a correspondence with a gentleman respecting the relative electrical state of the atmosphere and earth, and observing a pair of bright ordinary grocer's scales on the potboard in my kitchen, it occurred to me that, *as electricity was the cause of evaporation*, if I substituted silk for the chains of one of the scales and suspended them in the open air out of all draught on the north side of a wall, they would determine the question, since the one suspended by chains would be connected with the earth by a stout copper wire I attached to the hook in the beam, whilst the other would be insulated from it.

Casually observing the apparatus during October, November, and December, I noticed a very decided excess of evaporation from the insulated vessel, and thereupon decided that the evaporating influence of the atmosphere was much in excess of that of the earth, and so gave the balance no further consideration; but a couple of months later, that is in February, I chanced to see that the excess had been all the other way, a fact that left me no option but to observe the apparatus daily, and so I substituted fine copper wire for the remaining chains, suspended a small dish for weights to the scales, as I had previously done to the insulated one, and made a safe for its safe keeping, and thus imposed on myself the task of registering it night and morning.

Suffice it to say, then, that in 1846, the period of the first potato blight, the air was positive and the earth negative; but a change gradually took place to 1848, when the cholera presented itself to our shores, and fully developed itself in 1849, when the balance gave the immediate opposite information to that of 1846. Now, however, as regards evaporating influence, the earth is quite at a discount and so is agriculture.

With the gradual decrease in the electrical state of the earth, then, have gradually disappeared reptiles and ague, whilst blights, diphtheria, &c., have entered on the stage, diseases of a positive atmosphere that now makes itself felt even in the "lovely month of May," or even June. With such trifles, however, the public are in no way concerned.—Yours, &c.,

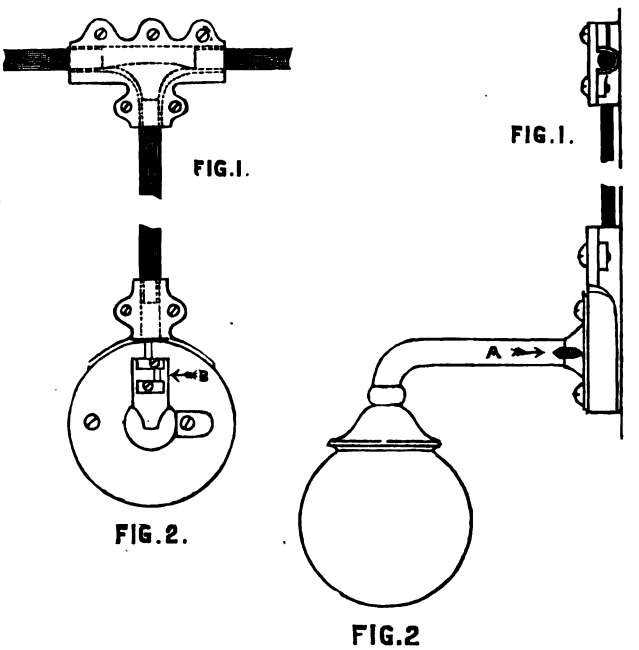
FRANKLIN COXWORTHY,
Author of "Electrical Condition" of 1848.

ELECTRIC LIGHT ON BOARD SS. "UMBRIA" AND "ETRURIA."

Messrs. J. D. F. Andrews and Co., Woodside Electric Works, Glasgow, have just completed on board ss. "Etruria" the last of two installations which, in their proportions, surpass anything that has hitherto been attempted in the application of electric light to steamships.

In the "Umbria" and "Etruria" the installations consist of about 850 lights each, and we append a description of one of the installations, which will, we have no doubt, be interesting to our readers. The description applies to both installations.

The space allotted to the electric machinery is unusually large, measuring 32ft. by 14ft., and is situated on the lower deck, midships, forward of the engine room. Here are placed four Brotherhood engines, two abreast, back to back, three having cylinders 8in. diameter by 6in. stroke, and the other 6in. diameter by 4½in. stroke. The small engine drives a Siemens 200-light machine, and the other three a 350-light dynamo each. Swan glow lamps are used, and of these 90 are distributed in the engine room, stoke holes, &c. The wires conveying the current to these lamps are covered with india rubber and a special composition for resisting sea water, and they are sheathed over all with iron wire, as a substitute for the tube generally used in engine rooms and such places.



The joints between the branch and main wires are protected by a small T shaped joint-box (Figs. 1 and 2). Each lamp in the engine room, as also in every other part of the ship, is fitted with a very simple switch A (Fig. 2). It consists of a screw severing connection to the lamp from the ship, which is used as a return. A fusible connection is also attached to each lamp (B, Fig. 2).

The engine room lights are divided into two circuits, each with a separate switch, and each stoke hole is also on a separate circuit.

The dynamos are connected to the main switchboard on the bulkhead close to the engines. To this switchboard also are brought the six main circuits that supply the ship.

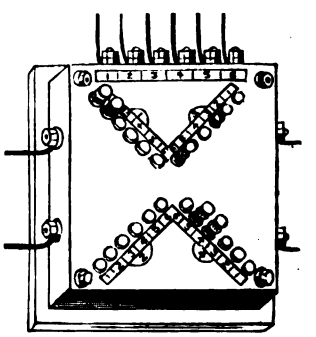


FIG. 3.

The switchboard (Fig. 3) consists of an iron box about 4ft. deep, with its opening against the bulkhead. In the face of the box are four rows of six holes, each 2in. in diameter, radiating from the centre, and the box is half filled with a board of teak wood with corresponding holes. In each of the holes in the teak wood are fixed copper springs, one on each side of the hole, one spring of each hole of a row connected to a brass strap in communication with one of the machines, the other spring being joined to a circuit of lights in the ship.

A brass knob with a stem and an insulated ring at the end

Digitized by Google

of the stem is pushed into one of these holes when the machine is to be connected with one of the circuits. The corresponding holes in each circle are joined together, so that by removing the plug from the hole in one position of the row and placing it in the corresponding hole in another the circuit will be joined to another machine. The circuits are numbered, starting from the stem of the ship, the first circuit supplying the night system, in which are about 200 lights, including those in the engine room and stoke holes; No. 2 circuit lights the after portion of the ship; No. 3 lights midships; Nos. 4 and 5 supply the saloon, ladies' saloon, music room, &c.; No. 6 supplies all lights forward of the saloon. Each of these main leads is carried to a group of switches at the junction of the main and branch leads, where there is also a fusible connection. Each of these switches controls a group of about 30 lights, and they are placed in boxes recessed in any convenient places—in passages generally and at the foot of stairs. The switches are constructed of a brass box, and on a similar arrangement to that described as being used in the main switchboard, except that the plug cannot be entirely withdrawn. In appearance this switch resembles the ordinary steam wheel valve (Fig. 4). The main branch fusible con-

The holder is also of new design, although the same as used by this company in their installation on the "Ems" and various other installations. It consists of four spring prongs formed from a brass tube; two of these grip the neck of the lamp, nection, which protects the wires, is a small circular block of wood with a groove across it, in which is laid a piece of lead wire, No. 16 B.W.G., connected at each end to a screw which projects at diametrically opposite sides of the block. The switch and fusible wire are connected together by a loop of wire. The small branch wires lead to the lamps direct without the intervention of other fusible connections, but in the

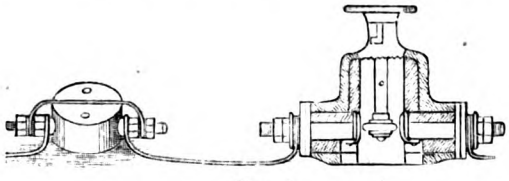

Fig. 4.

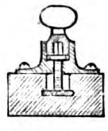

Fig. 5.

back-block of the lamps there is a piece of No. 20 lead wire, which protects the lamps, and also in the event of a defect shows in which lamp it is (Fig. 2).

In addition to the switch inside the room or in the lamp, there is also a switch of the same kind placed in the return wire in the passage, one for each state room (Fig. 5).
which is made of plaster of Paris, knobshaped to suit them. The other two have saucer-shaped ends, and press on brass contacts, held in the plaster. As will be understood, one of the prongs is insulated from the rest by a small piece of wood, forming the body of the holder, the insulated prong being attached to a pin passing through the centre of the wood. The holder is screwed on to the nozzle or nipple of the electric bracket, and in screwing it the pin holding the insulated prong meets with the wire projected from the end of the nipple, thus making contact with the central wire fitting (Figs. 6 and 7).

Altogether 103 lights are used in the lighting of the main dining saloon, 84 of which are suspended over the tables in 3-light electroliers, hanging about 2ft. 6in. from the ceiling (Fig. 8). The remainder of the lamps are in small brackets and pendants (Fig. 6), so as to give light over the side seats. The lighting of the saloon is very effective.

Above the saloon is the music room, having 17 lights round the walls and over the piano and organ. The smoking room has also 17 lamps. The remainder of the lamps are distributed about the ship, 172 being in the state rooms. All the fittings are silver plated, with the exception of those in the galleys, seamen's quarters, and engine room.

On the upper deck, just outside the engine room, is a cast-iron box, containing two switches, and connecting terminals for the Andrews arc lamps. These lamps are of the same design and construction as those adapted to a masthead light on board the North German Lloyd Company's ss. "Ems" and "Eider." The lamp is of great simplicity, and is well suited

Fig. 6.

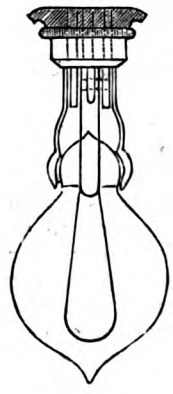

Fig. 7.

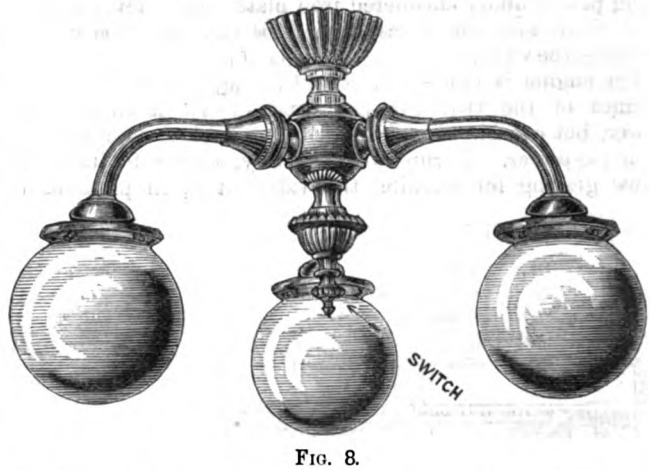

Fig. 8.

for the use of those not well conversant with electrical matters. In this case the lamp is arranged with double carbons. These installations have been carried out in all their details under the personal supervision of Mr. Andrews, who also worked out the various fittings here illustrated.

DOMESTIC ELECTRIC LIGHTING IN NEWCASTLE.

One of the latest examples of the application of electricity to the purpose of the artificial illumination of dwelling houses has just been completed at the residence of Charles Mitchell, Esq. (of Sir W. G. Armstrong, Mitchell and Co.), Jesmond Towers, Newcastle-on-Tyne. The whole of the installation has been arranged and the work carried out by J. H. Holmes and Co., electric light engineers, of the same city.

When the question of the adequate illumination of the building came under consideration, the merits and demerits of the only two systems available—gas and electricity—were carefully compared, and the superiority of the latter became so apparent that it was decided at once to adopt it, and to light the whole of the reception rooms, billiard room, and hall, to the complete exclusion of gas lighting.

It was manifest that, to have perfection, some means of storage must be provided, so that a light might be obtained at any time, whether of the day or night, without the necessity of starting the engine. This was accordingly supplied in the shape of an accumulator, composed of a number of secondary batteries.

With regard to motive power, it was an open question whether a steam or a gas engine should be employed; as the building was to be heated by steam it would only have been necessary to increase the size of the boiler provided for this purpose, but taking into consideration the advantages of the gas engine, its readiness to start at a moment's notice, its free

Digitized by Google

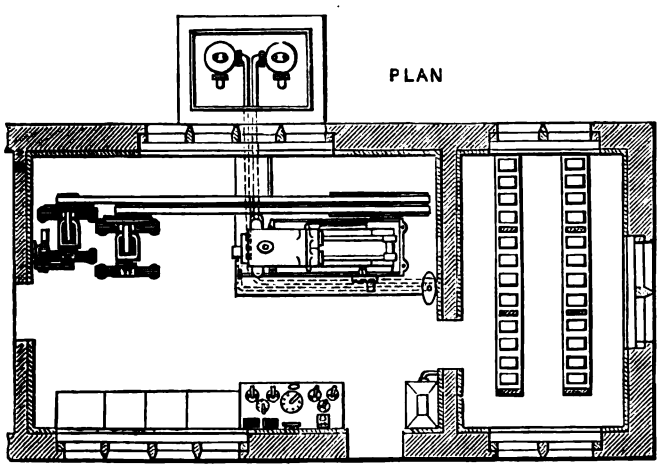
dom from smoke and exhaust steam, and its need of very little attention, it was ultimately decided to make use of this motor.

Owing to peculiarities in the situation, it was necessary that the engine room should be built at a distance of about 100 yards from the house, and the current is carried by means of copper cables placed on insulators fixed to the intervening trees.

Adjoining the engine room, and communicating by a doorway, is placed the accumulator house, in which ample provision for ventilation is secured by windows in three of the walls, and sufficient space allowed for access to both sides of the glass cells to enable a thorough examination of them to be made at any time. The floor of the battery house is composed of asphalte instead of cement, so as to be proof against any acid which might be accidentally spilt upon it, and the pitch pine shelves carrying the cells are coated with a special composition having similar properties, but of more easy application than the bitumen generally used for this purpose. The walls and ceiling are cleaded with wood.

In the engine room special care has been taken to keep pipes, wires, &c., out of sight as much as possible, the former being placed under chequered iron plates let in level with the tiled floor, and the wires carried behind the wood cleading covering the walls.

The engine is one of Messrs. Crossley Brothers' Otto gas engines of the twin cylinder type, of 12 nominal horse-power, but capable of indicating, when worked to its utmost, 25 horse-power. It runs very silently, owing to its having screw gearing for working the valve shaft, in place of the

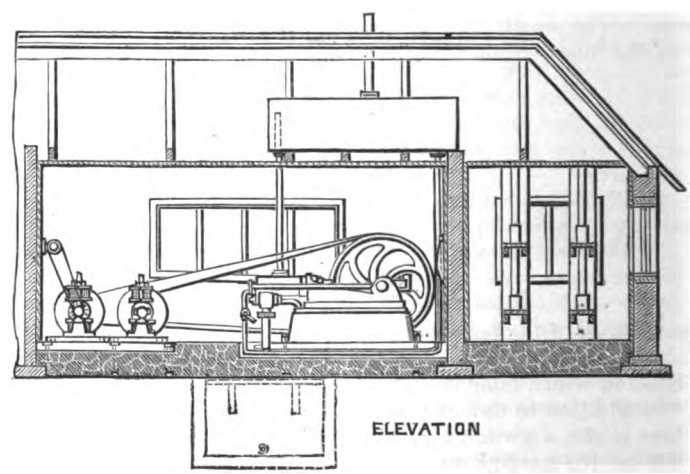


Engine and Battery Sheds.

usual bevel gearing. According to specifications this engine is fitted with Stauffer's lubricators, instead of those of the ordinary type, and the increased economy and cleanliness resulting from the use of solid oil fully justifies this its first application to English gas engines. The water tank, which generally forms such an unsightly object in a gas engine room, is in this instance entirely concealed from view, it taking the shape of a flat tank resting on the roof timbers above the wood ceiling. The hot water pipe is carried in a direct vertical line from the cylinder jacket to the tank above, the return pipe passing down the wall from the other end. Ventilators in the roof provide a current of air for keeping the tank cool, and the steam which otherwise might deposit moisture on the machinery is conducted to the open air through a pipe attached to the lid of the tank. The exhaust pipes are carried through the wall into the cast-iron exhaust boxes, communicating with a chamber below the ground level, from whence the gases find their way to the outer air through an iron grating and two feet of loose stones. By this the usual noise due to the exhaust is done away with.

The fly-wheel of the engine is of a special design, being of extra weight, and the rim turned with a double convex surface for receiving the two endless leather belts, which convey the power direct to the dynamos without the intervention of a countershaft. The dynamos are mounted upon sliding rails fitted with adjusting screws for the purpose of tightening the belts. These machines are of the Siemens vertical type, are shunt wound and each capable of supplying sufficient current for 100 incandescent lamps at 100 volts electromotive force. The dynamos run at a speed of 900 revolutions per minute, and regularity of motion is ensured by heavy fly-wheels attached to the pulleys, and rotating with them. The dynamos were specially built for this installation, and are fitted with brush holders, which may be adjusted to bring the brushes away from the commutator, and thus allow of one dynamo being run merely as a loose pulley; in case the current required is not more than the other dynamo will supply, a small pulley is fitted to the commutator end of one of the machines and drives a tachometer, or speed indicator, placed on a bracket on the wall.

The wires from the dynamos and the secondary batteries are led to a switch-board which takes the form of a horizontal mahogany table 5ft. long by 2ft. 6in. wide. All the connections to the switches are made on the under side, the whole of the front and ends being closed in and panelled. On the switch-board are placed the ammeter, two automatic switches, the starting switch, two dynamo switches, and three ammeter switches; the automatic switches are placed one in each positive wire leading from the dynamos, and serve, by breaking the circuit, to prevent the current from the accumulator running to waste through the machines in the event of their potential falling through accidental stopping of the engine, or any other cause. Three switches are arranged, enabling the current in the battery, or either dynamo circuit, to be shunted through the ammeter for the purpose of measurement. From the last four cells of the battery wires are led to the regulating switch,



which enables the number of cells on circuit to be varied according to the difference of potential desired between the mains.

Although the gas engine is of large size and is not fitted with a self starter, it is easily set in motion by one man; the starting switch consists of a number of resistance coils, which allow the current from the batteries to pass to the dynamos, and to be gradually increased in strength until sufficient to cause the dynamos to revolve, as motors pulling the engine round during the first few explosions.

The storage battery or accumulator used consists of fifty-one cells of the latest type manufactured by the Electrical Power Storage Company, having glass boxes containing thirteen plates each, so that the positive plates, which are smaller, are each of them between two negatives. These cells have, during the three months they have been working, given great satisfaction, and although their discharge current is only thirty amperes, they are capable of regulating the current from the two 100-light dynamos so perfectly as to show no variation at all in the brightness of the lamps.

As before mentioned, the current is carried to the house by covered copper cables suspended overhead to the intervening trees, and then is distributed throughout the house by wires run under the floors or skirting boards. Every branch wire has a proper fusible cut-out, and in many instances these are grouped in brass boxes let in flush with the surface of the skirting board

Digitized by Google

and painted to correspond. The whole of the switches used in the installation are of J. H. Holmes' patent "instantaneous break" type, which, it is said, render it impossible to form a dangerous "arc" in breaking the circuit, however slowly the handle may be turned, and are thus safe for use by ordinary persons.

The incandescent lamps used are the "Edison-Swan," requiring an E.M.F. of 100 volts, and ·6 ampere current; they are all arranged in parallel circuit, and are carried by the new "vitrite holders," which answer their purpose well in this the first instance in which they have been practically used.

The most notable feature of the lighting arrangements is the illumination of the picture gallery, a room 75ft. long by 30ft. wide and 25ft. in height. Lamps to the number of 120 are distributed in groups of six lights each round the room at a height of 13ft. from the floor, and are carried by specially designed pendants suspended by means of coloured flexible wire. The room is amply lighted, and the way in which the various colours in the pictures are brought out has been much admired by all who have seen them. The lamps are divided into three sections, controlled by separate switches. Turning to the other apartments, in some of which there are as many as fourteen lamps, we find them grouped on light polished brass electroliers. They are controlled by means of switches placed on the wall of the room just at the door, so that on entering the light may be instantly turned on, and extinguished again on leaving. The billiard table is amply illuminated by six lamps fixed to the old gasolier, the wires are run down inside the gas pipes, and each Swan lamp replaces three of the gas jets previously found necessary. In many of the bed rooms are placed reading lamps, which are quite portable. The electric current is brought to them through very thin flexible silk-covered wire, and the connection is effected by a plug entering a socket fixed to the wall. Such lamps are particularly useful in case of illness, as they give forth abundant light without the usual accompaniments of noxious products of combustion, and enable the invalid to read in bed with comfort.

With regard to the practical working of the apparatus, it need only be said that everything has worked admirably from the first lighting up on December 23rd last; and since that date it has always been possible at any time, whether of the day or night, by the mere turning of a switch handle, to obtain a brilliant, soft, and steady light.

The engine is attended to by the man who fires the boiler that supplies the steam for heating purposes, and during the winter it was found necessary to run the engine an hour or two before dark and continue till about nine o'clock; at the present time, however, the engine is run from three to six, charging the accumulator, which then supplies the ordinary needs in the way of light in the house during the evening. On Saturday the charging is continued for a longer period, so as to store sufficient energy for producing the light on Sunday night, and thus render it unnecessary to start the engine on that day.

THE VAN RYSSELBERGHE SYSTEM OF SIMULTANEOUS TELEGRAPHY AND TELEPHONY.

BY M. CHAS. MOURLON.

Since the first installations of the telephone in the commercial centres of the world it has been seen how admirably the invention of Graham Bell has lent increased facilities to the transactions of commerce and of industry, and it has only remained, in order to enable us to derive the greatest possible benefit from that invention, to extend its use to long-distance communication; not merely from house to house, but from town to town, and from country to country. Some idea has naturally been entertained of utilising the telegraph poles already in existence by placing upon them for purposes of telephonic experiment a wire or wires parallel to those of the telegraph. Directly, however, that is done we find an apparently insurmountable obstacle in the way of success in the shape of "induction," which has the effect of producing in the telephone a frizzling sound, which, for want of a better name, has been called "telephonic frying." These discords, which drown articulation, and render all communication impossible, proceed from the telegraphic currents conveyed by the wires adjoining or in the vicinity of those employed for telephony. It is in effect a reciprocal influence exercised by one conductor upon another, which is parallel to it, and it is governed by the variation of the electric current in the disturbing circuit. Such was the great obstacle opposed in the first instance to long-distance telephony. If these repercussive noises were of such intensity in the circuit of a wire which was merely in the vicinity of a telegraphic conductor, what would have been the result if a telephone had been placed actually in the *circuit* of the telegraphic wire? Could one have dreamed of suppressing the tumult, the deafening uproar which would then have arisen? Nevertheless that is the problem which M. Van Rysselberghe has had the audacity to attempt and to solve. We say audacity, because the difficulties of the problem were not only great, they were numerous.

Having once mastered the induction it was necessary to maintain the secrecy of the telegraph by rendering its signals inaudible in the telephone; it was necessary to prevent the possibility of the telephone intercepting even the smallest portion of any telegram passing by the wire to which it was connected, and it was required to find the means by which the telephonist having the telegraph circuit in his charge should be unable to prejudice that circuit, as by interfering in any way with its conduction or insulation or by putting it to earth. That others have had presented to them the same ideas, and that they have engaged in the discussion of the same problem, before or after M. Van Rysselberghe, it is quite possible. The fact, however, is incontestable that to him alone the honour of its practical solution is due.

The Van Rysselberghe system is based almost solely upon the remarkable fact, discovered by him, that *when the suddeness of the emissions and extinctions of the currents is eliminated those currents become inaudible in the telephone.* For the sudden charges of electricity now in use for telegraphic purposes he substitutes *gradual currents*; that is to say, currents which gradually increase at the commencement and as gradually decrease in strength at the end of each signal. This graduation, which occupies but an infinitesimal portion of time, is obtained by the intercalation in the circuit of small graduating electro-magnets, or, again, by placing upon the line certain condensers which act as derivators, or, finally, by a combination of electro-magnets and condensers absorbing a certain quantity of the current, which they restore on the circuit being broken. Under the influence of the currents graduated in this manner the diaphragm of the telephone is yet subject to movement, but *it no longer vibrates.* The telegraphic current, therefore, produces no *sound* in the telephone. In other words, the telegraphic currents are completely silenced or rendered inaudible whether they be direct, induced, or derived.

By means of this system not only can an effective telephonic service be organised from town to town by utilising the ordinary telegraph poles to carry the telephone wires, but the telegraph wires can themselves be employed for the purpose. The system is one of anti-induction, and completely assures the independence of the two services. It establishes between the telegraph and the telephone circuits a separation of such a kind that, whilst the rapid undulations of the low tension currents of the telephone are readily transmitted, an impassable barrier is opposed to the telegraphic currents, which, it is scarcely necessary to observe, are of an essentially different nature. The greatest beauty of the system is its simplicity, and this will be readily understood upon an inspection of the accompanying diagrams.

In the following Fig. 1, the letters M and R represent respectively the manipulator and receiving instrument of any telegraphic apparatus. P is the battery; E_1 and E_2 are the two graduating electro-magnets, one of which is placed between the battery and the manipulator, and the second between the manipulator and the line L; C is a graduating condenser, placed in derivation upon the line between the two electro-magnets. This condenser, which is of low capacity, is connected on the one side to the line, and on the other side to the

Digitized by Google

telephone branch T. By means of this arrangement the telegraph office A and the telephone office B are entirely independent of each other, and are able to employ the same wire for their simultaneous operations, without the slightest interruption resulting to either service.

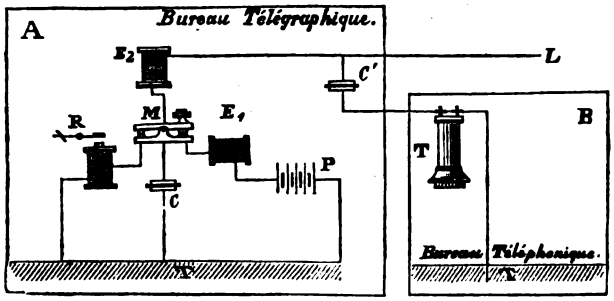


FIG. 1.*

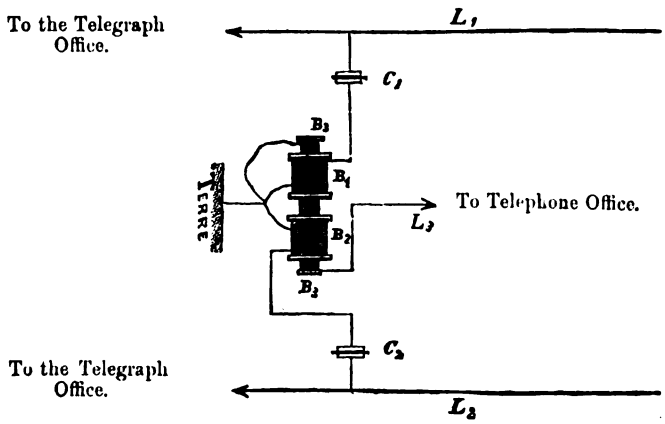

FIG. 2.

Figure 2 represents the arrangements for coupling two distinct telegraph wires, L_1 and L_2, in a complete telephone circuit. C_1 and C_2 are two *condensateurs separateurs* of feeble capacity. B_1 and B_2 are two differential coils, influencing a third coil, B_3; one of the ends of each of these coils is in direct communication with the earth. The other end of B_1 is connected with the telegraph line L_1, B_2 with the line L_2, B_3 with the line L_3, which leads to the central telephone station. From the preceding it will be seen that, contrary to an idea which has been largely entertained, M. Van Rysselberghe has not had recourse to microphones or telephones of special construction for the simultaneous transmission on the same wire of telegrams and of verbal messages. The whole of the adaptation or appropriation necessary takes place in the offices of the telegraph. It is not the telephone but the telegraph which calls for modification, in that the signals of the latter must be silenced. That being done, the dual operation is both possible and practicable with the microphones and telephones in ordinary use. Experience has demonstrated that the apparatus as at present employed enables the voice to be transmitted to more than 100 kilometres (62 miles) of distance; but the results, good, bad, or indifferent, which have been obtained in each particular case have not been the results of experiments with the anti-induction system of M. Van Rysselberghe, nor with his method of simultaneous telephony and telegraphy, they have indicated solely the efficiency of some telephonic services. Independently, however, of the system we have described, M. Van Rysselberghe has closely applied himself to the improvement of the microphone. He has augmented in a great measure the power of his apparatus in a simple but yet effective manner. It is well known that in the carbon transmitters and microphones the electric reproduction of the human voice is due to the variations of resistance which are created in the carbon contacts under the influence of the vibrations which agitate the diaphragm of the microphone. The researches and experiments of M. Van Rysselberghe confirm the hypothesis that *the variations of the resistance of the contacts are of much more relative value, and the variations of the current which result from them are much more considerable when the total resistance of the circuit is more feeble.*

(TO BE CONTINUED.)

* We are indebted to M. Mourlon for the accompanying illustrations.

ELECTRIC CALLS WITH CARBON CONTACTS FOR RAILWAYS.*

The appliances proposed and tried for solving the problem of making and breaking electric contact on the passage of a train have encountered difficulties in actual working, although at first sight the means proposed seemed among the easiest. This question, so important, not only for electric calls and for instruments for measuring the speed of trains, but especially as an integral portion of the block system, whether automatic or not, has been studied in its different phases by the company working the Dutch State Railways.

The first contacts put down, intended to register the speed of trains over large bridges, were established by means of pedals, which were worked direct by the wheels.

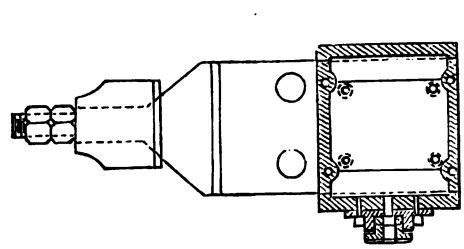

FIG. 1.

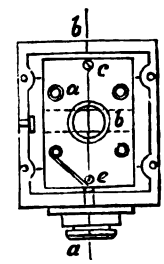

FIG. 2.

The pedal, fixed on a horizontal shaft at right angles to the rail, was depressed by the pressure of the wheels. The shaft made a partial revolution, and, by means of a lever, gave a reciprocating motion to a vertical spindle. This spindle brought into contact two insulated copper springs, which thus set up an electric current supplied by a line battery.

The pedal was again raised by a spring acting in the contrary direction; and this spring, depressed by each wheel on passing, soon got out of order. Moreover, the pedal itself, although of steel, soon became unfit for use.

To avoid shocks, contacts depending on the deflection of the rail were tried, which consisted of a lever, the short arm of which was below the rail, while the pin serving as a fulcrum was carried by a chair attached to an iron bar placed between two sleepers. The long arm transmitted its motion to another lever with unequal arms, and thus made contact.

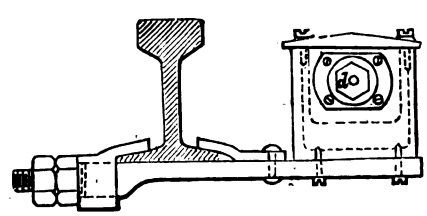

FIG. 3.

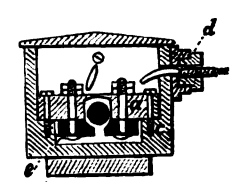

FIG. 4.

These appliances worked well, but they had this great drawback, that they were deranged every time the sleepers were moved. On constructing an appliance independent of these parts, the result obtained was insufficient; and that because the motion of the lever in the first appliances resulted more from the compression of the timber than from the bending of the rail.

Instruments with mercurial contact on the Wiesenthal system gave no better result, because the mercury became oxidised by the sparks caused at each interruption of the current.

Starting from a totally different principle, the company's telegraph inspectors have brought out an apparatus which

* From *L'Electricien*.

Digitized by Google

utilises the trepidations of the rail so inconvenient to the other systems.

The arrangement shown by Figs. 1, 2, 3, and 4 represents a cast-iron box, mounted on a wrought-iron plate, which is fixed to the rail by a bolt; in the box, and attached by the screws *c c*, is a piece of ebonite, *a*, in the middle of which is a cylindrical recess, with a copper wire stretched between two screws below it.

Two pieces of carbon, *e e*, are attached to the underside of *a*, there being a space of 1 centimetre (about $\frac{3}{8}$ inch) between the two. A carbon ball rests on the two carbons *e e* in the cylinder *b*.

The insulated wire of a cable, introduced into the box by an aperture in the screw *d*, is connected with one of the carbons, while the other is put in contact with the box, in communication with the earth by the cable covering. In the appliances, which are intercalated in the circuit, two screws, *d*, are used. The second piece of carbon is not connected with earth, but with the second insulated wire.

A battery supplies a permanent current from earth to earth through the carbon contact, so that, when the contact is broken, the current, no longer going to earth, ceases to circulate.

A train passing, and causing the ball to move, owing to the trepidation of the rail, brings about these interruptions of the current, which are registered by a Morse receiver, the paper band of which advances, by means of clock-work, exactly 5 centimetres (2 inches) a minute.

The armature is placed below the coil in such a way that the attraction of the electro raises it. When the current is interrupted, the armature, pulled back by a spring acting in a contrary direction, brings the sugar roller and the paper band into communication.

The sign given by fast trains is a continuous line; and by trains running at a moderate speed, a series of dots.

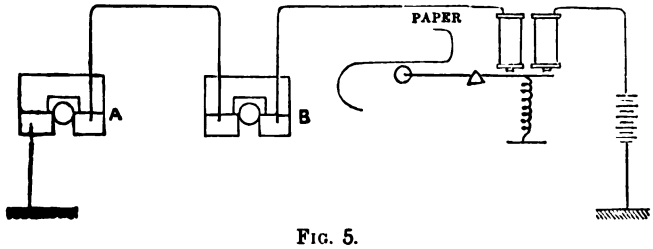

FIG. 5.

Fig. 5 shows the whole installation. The length of paper, unrolled between the commencement of the signs, indicating the passage of the train from A to B, gives the duration of time required to traverse the known distance A B, and consequently the mean speed of the train between these two points.

It should be remarked that, in consequence of the number of cracks in natural charcoal, the use of artificial charcoal is to be preferred.

L. DUFOUR, Engineer, Utrecht.

ON THE SEAT OF THE ELECTROMOTIVE FORCES IN THE VOLTAIC CELL.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

(CONTINUED FROM PAGE 423.†)

TABLE OF CONTENTS.

CHAPTER II. *Argumentative.*

7. Summary of the theoretical views which can be agreed to, and of the remaining points in dispute.
8. Views of Clerk Maxwell.
9. Views of Pellat.
10. Argument that the Peltier effect does not necessarily measure electromotive force at junctions.
11. Hydraulic illustrations of the difference between Peltier and Volta forces, according to the views of the writer.
12. Summary of condensed statements embodying orthodox views.

7. The result of the survey in regard to our special subject of discussion may be summed up thus:—(1) That there is certainly an E.M.F. at the junction of two different substances, or even of the same substance in two different states; and (2) that the total E.M.F. of a circuit is the algebraic sum of all such contact-forces at every junction in the circuit. I do not know that these two propositions could be passed *nem. con.*, but I believe that, provided they are properly understood, the dissenting minority would be a very small one. It is probable that Prof. Exner would be in the minority, but I am unable to be sure of any one else.

We can also make a negative proposition which will command almost universal assent, viz., that if in the above second proposition, instead of the sum of the contact-forces at *every* junction, we attend only to the contact-forces at the *metallic* junctions, the proposition will no longer be true. This fact, that the metallic junctions are insufficient to account for all the E.M.F., was established by Becquerel, De la Rive, and others, and still more thoroughly and exhaustively by Faraday. It is the easiest possible thing to make a number of batteries which shall give a current without any metallic junction whatever. Faraday gives some thirty of them.*

One more certain proposition we can lay down—viz., that whenever a current is produced, the energy of the current must be maintained by absorption of heat, or by chemical action, or by gravity, or by some other such agent, not by mere contact.

So much being agreed to, what remains of subject-matter for controversy? This: A voltaic circuit contains at least three junctions; what is the value of the contact force at each of them? and especially to which junction is the major part of the observed E.M.F. due? Is it the zinc-acid? or is it the copper-acid? or is it the zinc-copper? There is no other question. The old chemical and contact controversy has died out, but another controversy remains. Most physicists probably would say to-day that the major part of the E.M.F. of the cell resides at the zinc-copper junction. This was Volta's view, and this is the view of the text-book writers taught by Sir William Thomson. Some few would say at the zinc-acid junction, and among them I must confess myself.

It is no question between contact and something else; it is a question between a feeble energy-less metal-metal contact, and an active energetic metal-fluid contact with potentialities of chemical action straining across the junction. What is there to distinguish between the two? Electrostatic experiments with air-condensers prove nothing. They add up three E.M.F.s, air/M + M/M′ + M′/air, and give you the sum. The experimenters usually assume that M/M′ is what they are measuring, but there is no proof to be given in support of the assumption, except that if you substitute water for air the effect remains almost unaltered; but then water contains oxygen as the active element the same as air does. Well, then, it may be urged, the effect is the same *in vacuo* and in hydrogen as in air; and to this I answer, Not proven.

Can any further assertions be made with reference to electroscopic experiments as bearing on voltaic theory? Yes, it can be asserted that by adding up the Volta effects for A/B, for B/C, for C/D . . . and for Z/A, you arrive at the total E.M.F. of the circuit A, B, C . . . . A. True, but what then?

The Volta effect you call A/B is really

$$\text{air/A} + \text{A/B} + \text{B/air};$$

that you call B/C is

$$\text{air/B} + \text{B/C} + \text{C/air};$$

. . . . . .

and that you call Z/A is

$$\text{air/Z} + \text{Z/A} + \text{A/air}.$$

Add them up, and you get

$$\text{A/B} + \text{B/C} + \ldots + \text{Z/A},$$

which *must* be the E.M.F. of a circuit by common sense—*i.e.*, without violent experimental disproof, which no one has ever attempted to give. This fact, that the sum of the Volta effects equals the sum of the true forces, in a closed circuit of any conducting materials, has, nevertheless, caused persons to suppose that air/metal forces are negligibly small. But it is clear that they may have any value they like without affecting the truth of the law. They could only effect it if air/M were not equal to −M/air. The experimental proof of the summation law therefore establishes that air/M *is* equal to −M/air, as well as the important fact that the contact-force at each junction is independent of all other junctions of what kind soever.

8. Leaving electrostatic determinations as without bearing on the point at issue, let us ask, Is there no direct and straightforward way of measuring the actual E.M.F. at a particular junction without disturbance from other junctions? The answer is most clearly given by Clerk Maxwell†, thus:—

"Sir W. Thomson has shown that if Π is the coefficient of Peltier effect or the heat absorbed at the junction by unit current in unit time,

* Reprinted from the *Phil. Mag.* for April.

† Scarcely any of this portion was read at Montreal, but it was given in substance to the Society of Telegraph Engineers on 26th March.

* Exp. Res. ii. 2020. Dr. J. A. Fleming describes another of these batteries in *Phil. Mag.*, June, 1874, and gives some very cogent and readable arguments in favour of the "chemical theory" of battery E.M.F., suggesting that the difference of potential between the terminals of a battery on open circuit is due to potential chemical combination of the metals and electrolytes. He does not, however, explain the old Volta experiment; and, as Prof. Chrystal has pointed out (*Encyc. Brit.*, "Electricity," p. 99), upholders of the chemical theory are bound to explain this.

† "Electricity and Magnetism," vol. i., art. 249. Abbreviated here, because so easy of reference.

Digitized by Google

then JΠ is the E.M.F. at that junction acting with the current. This is of great importance, as it is the only method of measuring a local E.M.F.; the ordinary method of connecting up by wires to an electrometer being useless. This Peltier measurement is quite independent of the effect of contact-forces in other parts of the circuit. But the E.M.F. so measured does not account for Volta's force, which is far greater and often opposite. Hence the assumption that the potential of a metal is to be measured by that of the air in contact with it must be erroneous, and the greater part of Volta's E.M.F. must be sought for, not at the junction of the two metals, but at one or both of the surfaces which separate the metals from the air or other medium which forms the third element in the circuit."

And in another place he says* :—

"In a voltaic circuit the sum of the E.M.F.'s from zinc to electrolyte, from electrolyte to copper, and from copper to zinc, is not zero, but is what is called the E.M.F. of the circuit—a measurable quantity. Of these three E.M.F.'s only one can be measured by a legitimate process, that namely from copper to zinc. If we cause an electric current to pass from copper to zinc, the heat generated in the conductor per unit of electricity is a measure of the work done by the current, for no chemical or other change is effected. Part of this heat arises from the work done in overcoming ordinary resistance within the copper and the zinc. This part may be diminished indefinitely by letting the electricity pass very slowly. The remainder of the heat arises from the work done in overcoming the E.M.F. from the zinc to the copper, and the amount of this heat per unit of electricity is a measure of the E.M.F. Now, it is found by thermo-electric experiments that this E.M.F. is exceedingly small at ordinary temperature, being less than a microvolt, and that it is from zinc to copper.† Hence the statement, deduced from experiments in which air is the third medium, that the E.M.F. from copper to zinc is ·75 volt, cannot be correct. In fact, what is really measured is the difference between the potential in air near the surface of copper, and the potential in air near the surface of zinc, the zinc and copper being in contact. The number ·75 is therefore the E.M.F., in volts, of the circuit copper, zinc, air, copper, and is the sum of three E.M.F.'s only one of which has yet been measured."

With every word of Maxwell I cordially agree.

9. While on the theoretical aspect of the subject, it may be well to see what Pellat, as one of the best experimenters on it, has to say. Pellat substantially observes as follows :—

"Does the apparent difference of potential between two metals in contact indicate a real difference of potential between them? In all rigour, No! but the slight variation of its value when different gases or even liquids are used renders it extremely probable that there is such a real difference of potential, and that it is very nearly what is measured in electroscopic experiments."

As to difficulties connected with energy considerations and mere contact, he refers to Helmholtz‡ and Clausius§, who, he says, relieve him of all responsibility on this head.

The fact that the voltaic order of the metals is much the same as their order of oxidizability must have struck nearly everybody, and must also have been felt as a difficulty by the upholders of the efficacy of mere contact. Pellat considers he disposes of it thus :—"Since the E.M.F. of a pile is that represented by chemical action, and since by experiment voltaic contact forces have much the same values as the E.M.F. of piles, it follows that there is some vague relation between A/B and the heats of combination, say of substitution of one metal for another in a salt (as in a Daniell)."

He sums up his experimental conclusions as follows :—

(1) "Two different metals united metallically are covered, in the state of equilibrium, with electric coats of unequal potential."

(2) "This difference of potential only depends on the superficial coat of metal. It changes notably when the surface is mechanically scratched, becoming always more positive. As the scratching effect disappears with time, so does the extra difference of potential. The state of polish of the surface is immaterial, but traces of foreign substances, forming a coat so thin as to be invisible, are able to modify the value of the observed effect enormously."

(3) "The effect depends somewhat on temperature."

(4) "The pressure and nature of the gas surrounding the metals have a very distinct but extremely feeble influence, but, since the effect produced is a lagging one, it is probably due to some secondary cause, and it is probable that the difference of potential is really independent of the gaseous dielectric."

(5) "The difference of potential between the electric coats on two metals united metallically has the same value as the E.M.F. of an element of a liquid pile formed by these two metals, provided that the E.M.F. is determined before any alteration of the metallic surface wetted by the liquid has occurred; but these alterations produce themselves very rapidly."

Pellat's theoretical conclusions being short may also be here quoted, and I will number them on with the others.

(6) "It is extremely probable that the difference of potential between the electric coats which cover two metals connected metallically represents the true difference of potential which exists between them. No reason, either theoretical or experimental, can be invoked against the existence of a difference of potential between two metals in contact."

(7) "This last quantity has no connection with the thermo-electric E.M.F. measured by the Peltier phenomenon."

(8) "It has only a vague and distant connection with the difference of oxidizability of the metals."

Concerning these propositions, I may remark that while number 2 is likely to annoy contact theorists (though I know they have methods of explaining it away), numbers 4 and 5 are calculated to restore their equanimity. The five experimental conclusions I accept as in duty bound, only permitting myself to doubt the perfect generality of numbers 4 and 5 under all circumstances; but the three theoretical ones I am unable to wholly accept. Thus with respect to the second part of number 6, I beg entirely to differ from M. Pellat if I am called on to simultaneously admit number 7. Whether one is prepared to accept any of his theoretical conclusions or to reject them all, depends upon how one regards them. If in the way he himself intended, then I reject them all. If with one's own interpretation, then I say that the second part of 6 and 8 are true (though for "only a vague and distant" I would substitute "no"); and 7 is also true if it be held to refer to the quantity first mentioned in number 6, while number 8 refers to the other quantity. Number 6 I should also consider true if the prefix "im" be made to the fourth word.

10. Pellat then proceeds to explain why he considers the Peltier effect to be quite distinct from, and have no relation to, the true E.M.F. of contact. In explaining this he makes use of a piece of unpleasantly plausible reasoning, which I myself have heard Prof. Ayrton use, and which, when unexpectedly suggested, is so painfully benumbing that it is worth while to quote it, and to indicate its weak point. Pellat's statement of the argument is rather long; perhaps it can with advantage be abbreviated.

Two metals A and B put into contact are at different potentials, the difference A/B being due to and equal to the E.M.F. of contact. There is, then, at the junction not only the contact force E, but also the equal opposite force $-dV$, due to the difference of potential established. Either of these forces alone would resist or aid the passage of electricity across the junction and so give rise to a Peltier effect, but both together will do nothing of the sort; and so if there be any Peltier effect it must be some small residual phenomenon, or it must be due to some other and totally distinct cause.*

Prof. Ayrton's way of putting the argument, which I think he said he got from Sir William Thomson, was something like this. When Q units of electricity are transmitted against a force E, work EQ is done; also when they are transmitted up a difference of potential V′ – V, work Q (V′ – V) is done; but, in an open circuit containing an electromotive junction, V – V′ is produced by and is equal to E. Hence, at an electromotive junction no work need be done by a current; in other words, the existence or non-existence of a Peltier effect has nothing to do with the existence or non-existence of a local E.M.F.

The fallacy of the argument, in either form, lies in over-precise specification of locality; it gratuitously asserts as true for *the junction* what is only proved to be true for the whole circuit. It assumes that there can be no work done *at a junction* if it be perfectly easy to drive electricity either way across it—*i.e.*, if there be no work done *on the whole*.

11. To exhibit the fallacy, consider a hydrostatic analogy. Two vessels of water connected by a pipe in which is a motor of some kind, which, without leakage, exerts a specified force on the water and maintains a constant difference of potentials, but then remains stationary, doing no further work. We typify it feebly in the diagram by an impracticable close-fitting water-wheel driven by a weight without friction.

V – V′ is the equivalent of the force exerted at the junction, and everything is in equilibrium. It is perfectly easy for water to flow from one vessel into the other under the influence of the slightest extra force, for W helps the water up the hill V – V′, when the flow is in that direction; and, whenever the flow is reversed, it lets the water gently down again, taking all its energy out of it. If water is made to flow from A to B, say by pouring more into A, the weight W is lowered, or energy disappears (heat absorbed) at the junction; if it is made to flow from B to A the weight is raised, or energy (say heat) is generated at the junction. Thus there is a true Peltier effect at the junction despite the existence of V – V′ and its equality to the junction force, and yet no resistance is offered to the flow of water either way. Thus is the first form of the argument controverted.

To pump water from A to B by any other pipe would need work to be done equal to Q(V – V′), and to pump water against the force of W, acting alone, would also need work EQ; but when the water goes from A to B *viâ* W, or *vice versâ*, no work is done on the whole. Quite true; but the conclusion that no work is done *at the junction* by no means follows.

---

* Maxwell: Letter to *The Electrician*, April 26, 1879. Also "Elem. Electricity," p. 149.

† Further on (sect. 23) I point out that this statement is not quite true, but it does not affect the main argument.

‡ *Die Erhaltung der Kraft*, p. 47, where Helmholtz develops Volta's original hypothesis about an attraction of matter for electricity, of an amount depending on the kind of matter, so that it gets pulled one way or another across a junction of two dissimilar substances. He points out that the Volta effect is explained if zinc be granted a stronger attraction for electricity than copper has. This view he returns to in his Faraday Lecture 1881, where also he refers to Berzelius's electrical theory of chemical affinity. The opinions of Prof. Helmholtz are too weighty to be merely referred to in a footnote, but we may have occasion to consider them later.

§ *Die mechanische Behandlung der Elektricität*, chap. vii. §§ 2 and 3, where Prof. Clausius follows up the above idea by considering the *rôle* which heat plays in the matter, and thus hypothetically explains the Peltier effect also.

* Thus it may be, suggests Pellat, due to a slight difference between E and $-dV$ produced by the mere fact of a current passing; *i.e.*, contact E.M.F. with electricity at rest may be slightly different from what it is with electricity in motion.

Digitized by Google

Work *must* be done at the junction in proportion to the force there (by inspection of the diagram); and accordingly the existence or non-existence of a Peltier effect has *everything* to do with the existence or non-existence of a local E.M.F. This controverts the second form of the argument.

If the argument be now considered upset, are we to proceed to assert that the difference of potential, or force, concerned in the Volta effect, and the heat-destruction or generation concerned in the Peltier effect, are closely connected, and in fact different ways of observing the same thing? By no means. All we have proved is that the Peltier effect accurately and necessarily represents and measures the true contact-force at a junction. True we have considered a difference of potential V – V′ as produced by this contact-force in an incomplete circuit; and so it is. But nothing has been said to imply that this difference of potential has anything to do with what is observed in electrostatic experiments as the Volta effect. So far from this, I will assert that what is usually observed when two metals are touched and separated is not primarily a difference of potential between the metals at all. They are at different potentials when separated, no doubt, because they are oppositely charged; but they may have been at the same potential until separated. The real Volta effect is almost independent of the true contact-force, and of the difference of potential which

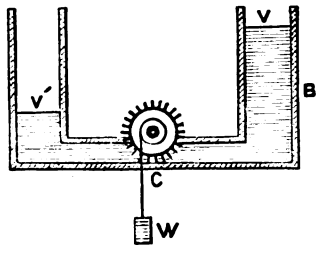

FIG. 14.

Hydrostatic analogue of the true contact or Seebeck force, and of the real though small difference of potential which it maintains between two metals in contact. A and B represent the two metals, C their junction; W is a weight driving a water-tight wheel until stopped by the difference of potential set up. The hydraulic raising or lowering of the weight represents the Peltier effect.

it produces. In other words, a good Volta effect can be observed when there was no difference of potential whatever between the metals when in contact.

According to my view the Volta effect is produced, not by a contact-force at the junction of the two metals, but by a contact-force at their free surfaces, between the metals and the air or other medium surrounding them. To represent this hypothesis by a hydrostatic model, we shall have to maintain the difference of level in the two connected vessels, not by a force at the junction, but by a force at the surfaces; say by using closing vessels and compressed air, or more pictorially by differently stretched elastic membranes or bladders tied over the tops of the vessels.

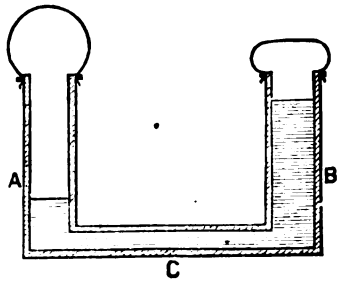

FIG. 15.

Hydrostatic analogue of the Volta effect, or *apparent* difference of potential produced by metallic contact, and of the opposite charges but uniform potential which it maintains between two metals in contact. The vessels are covered by air-tight elastic bags differently stretched.

Note that the difference of level in this case implies no difference of potential; and, as before, no work is required to transfer water between A and B. Hence it is not easy to distinguish this case from the former; and this difficulty of distinguishing between the two cases is what has given rise to most of the confusion. The only easy criterion is the non-existence in the second case of any Peltier effect at the junction C. Naturally it is possible and common for the two effects to be superposed, but they are essentially independent.

Since the two vessels in the second case are at the same potential, the way to observe the effect is to cut and seal the pipe at C, and then show that the vessels are differently charged; which is what Volta did. The model does not indeed represent the gradual change of potential induced as the distance between the condenser plates increases; and it is scarcely worth while to complicate the matter by making a more elaborate model. The thickening of the dielectric layer of a condenser, when its plates are separated, corresponds exactly to the thickening and strengthening of an elastic membrane; and rise of potential in the one case is accurately representable by increase of pressure in the other; but such considerations belong to general electrostatics, and have no special bearing on our present subject.

(TO BE CONTINUED.)

PHYSICAL SOCIETY.

At a meeting of the Physical Society, held on the 28th ultimo, a paper was read by Mr. Joseph Edmondson on "Calculating Machines," which, after discussion, was followed by a paper "On the Structure of Mechanical Models, illustrating some Properties in the Ether," by Professor G. F. FitzGerald.

The author had recently constructed and described before the Royal Society of Dublin a model illustrating certain properties of the ether (*Nature*, March 26). This model was one dimensional, but the author now showed how a tri-dimensional model might be imagined, though probably mechanical difficulties would render its actual construction impossible. Each element of the ether is to be represented by a cube on each edge of which there is a paddle wheel. Thus, on any face of the cube there will be four paddle wheels. Now if any opposite pair of these rotate by different amounts they will tend to pump any liquid in which the whole is immersed into or out of the cube, and if the sides of the cube be elastic there will be a stress which will tend to stop this differential rotation of the wheels. If, however, the other pair rotate by different amounts, they may undo what the first pair do, and thus the stress will depend on the difference between the differential rotations of these opposite pairs of wheels. If η represent the angular rotation of one pair, and ζ that of the other, the stress will depend upon $\frac{d\eta}{dx} - \frac{d\zeta}{dy}$. In order that these four wheels may not similarly work with any other wheel, it is necessary to place diaphragms dividing the cube into six cells, each a pyramid standing on a face of the cube. They must be so made that liquid may not be able to pass from one cell to another through the diaphragm or beside the paddle wheels. To effect this the floats on the paddle wheels would have to be drawn down while passing the diaphragms. Thus the energy of distortion of such a medium would depend upon

$$\left(\frac{d\zeta}{dy} - \frac{d\eta}{dz}\right)^2 + \left(\frac{d\xi}{dz} - \frac{d\zeta}{dx}\right)^2 + \left(\frac{d\eta}{dx} - \frac{d\xi}{dy}\right)^2.$$

And Maxwell has shown that this is also true for the ether. The faces of the cubes should be filled up with diaphragms, past which the paddles should pump liquid, and whose elasticity should be the means of storing electrostatic energy in the medium. The most complicated results follow from supposing the faces of the cubes of which the medium is constructed to have different elasticities. Such a structure represents a crystalline medium and vibrations would be propagated in it according to laws the same as those regulating the transmission of light in crystalline media. If the cubes were twisted the structure would be like that of quartz or other substances rotating the plane of polarisation. To represent magnetic rotation of the plane of polarisation it would be necessary to introduce some mechanism connecting the ether with matter. The author, in conclusion, insisted upon a view which regards the vibrations constituting light to be of the nature of alterations of structure, and not of displacement, executed in a medium possessing the properties of an elastic jelly.

SIXPENNY TELEGRAMS.

The following is an abstract of the correspondence on the above subject which has appeared in *The Times*. It appears to have originated with Mr. Martin J. Sutton, who, having regard to Mr. Shaw-Lefevre's statement that "the name and address of the sender are, except in the most abbreviated form, mere surplusage," pointed out that difficulties were likely to arise under such curtailment. After remarking that nearly the whole of his business correspondence was carried on by wire, he said that:—"I find we have 1,060 customers on our books of the name of 'Smith,' of which number no less than 323 are John Smith; 465 'Jones,' 96 of whom are John Jones; 450 'Browns,' 87 John Brown; other surnames such as 'Williams' and 'Robinson,' joined to other Christian names such as 'Richard' or 'Robert,' showing a similar relative proportion of identical appellations. The name in such cases being of little use alone, the address of the sender is practically the only means by which he can be identified. A country resident's postal address seldom corresponds with or even indicates his nearest telegraph office. The postal address is often the only one with which we are acquainted, and it would not be likely to occur to any one of the 323 'John Smiths' that we had another customer of the same name within 10 miles of him." Mr. Sutton concludes with the refreshing remark that what is wanted is not a lower tariff, but a greater number of country village offices, and suggests that if the Postmaster-General has £180,000 to spare, he had better spend it in extending the area of telegraphic communication. A somewhat lengthy reply to this appeared on the 7th inst. from a correspondent of *The Times*, who, after commenting upon the great extra expense to the Post Office, which will be due to delivery alone, says:—"Telegrams cannot, according to the Post Office statistics, be sent except at considerable cost. The average cost of a telegram now is 10d.; the average receipt 1s. 1d. For 6d. only a much shorter telegram can be sent, if a serious loss is not to be incurred. It has never yet been contended that the telegraph service should be conducted at a loss; in other words, that people who do not telegraph are to pay for those who do. Why should the working man, who, under the present system, probably never sends or receives a telegram from year's end to year's end, and would very rarely despatch one at the reduced charge, pay for the speculator on the Stock Exchange who conducts most of his business by telegraph, or for the bookmaker and his customers, and the racing tout, who are con-

Digitized by Google

tinually in correspondence over the public wires? On what system of charge will the public get most benefit from the opportunity of sending 12 words over the telegraphs for 6d.? It is obvious that if free addresses were still to be given, as their average length is 11 words, the Department could not afford to give a message of any appreciable length at all. A text of 5 words would mean a telegram of 16 words in all, and a heavy loss would be inevitable. If the address of the receiver only is sent free, 7 words are found to be average, and thus only 5 words out of 12 would be left for the text—a number which would be still further reduced whenever the sender found it necessary to state his name or address. In all cases in which the sender, in order to say what he wishes, and to give, if necessary, an indication from whom the telegram came, had to telegraph more than 5 words, he must pay more than 6d. Nor would he be able to extend his message by curtailing the address. This is a consideration which should govern the selection of a new tariff. With so high a number as twenty words for the minimum charge, the question hardly arises, as the cases in which it is necessary to exceed the minimum charge are comparatively rare. This is shown conclusively by the low average receipt for a message, 1s. 1d. But when the minimum charge is reduced, and the maximum number of words to be transmitted for it consequently becomes small, it is a matter of moment whether the sender of a message shall have free control over the whole document, or whether the addresses shall be a fixed quantity, the shortening or lengthening of which has no relation to the text. If a man, by using five words in his addresses instead of eleven, can save the Post Office the trouble of sending six useless words, why should he not be allowed to get the benefit of the six words which he saves in the text of his message? Now, when it is found that the average number of words used in addresses in foreign telegrams is five, while in Germany it is only four, it may reasonably be anticipated that English addresses may be shortened as much as foreign when it is to the advantage of the public to shorten them. Yet those who contend for free addresses would prohibit the transfer of the six words of address, whith now, unhappily, burden the Post Office wires, to the text of the message. Because in a few cases it may not be possible to write the necessary addresses in a few words, they would forbid those who correspond with short addresses, or who take the trouble to excise superfluous names, from reaping the advantage in a longer message. It is difficult to see the justice of such a procrustean measure. It is needless to say it costs as much to telegraph a word of an address as a word of a message. The address must be telegraphed to enable the telegram to be delivered, and the telegram is of no use unless it is delivered. There is no reason why a service which is absolutely necessary, and costs money, should be performed gratis. Brevity in telegraphing should, therefore, be encouraged in the interest of the senders of messages. The surest, in fact the only, way to secure brevity is to charge for every word. A system like the present, which allows free scope to prolixity in addresses, and gives so high a limit as 20 words for the minimum charge, is probably as wasteful as any system that could be devised. It is a mistake to think of 6d. as a limit. The proposed change is not the introduction of a 6d. telegram simply, but of telegrams varying in price from 6d. through every penny to 1s. If seven words are not sufficient for the message, or the addresses cannot be compressed into five, another penny will give an additional two words, and for 8d. seven words of address and nine of message, or five of address and eleven of message may be sent. Throughout the whole gamut the possibility of enlarging a message by curtailing the address will apply, if the word rate is adopted; whereas the system of free addresses will give a cramped message, not only at 6d. but for higher sums."

Other correspondents suggest "as an improvement the continuance of free addresses and a halfpenny a word on all telegrams, 6d. being the lowest charge This would allow 12 words instead of eight words, which would add essentially to the value of the boon of the sixpenny telegram and not hurt the revenue; that, in regard to the increased labour, and therefore expense, which will fall upon the Post Office in the delivery of telegrams in consequence of the curtailment of addresses under a word-rate, it is sufficient to say that every foreign State, and every private telegraph company, charges for addresses. That, as to the payment for addresses the case would be met and a leverage used for the economy of words in both message and addresses if the following rule were adopted:—One halfpenny for each word in the message, and half this rate for each word in the addresses of the sender and receiver. No telegram to cost less than 6d., and when excesses of this amount terminate in a farthing, the said farthing to count as a halfpenny. The words could be easily counted, and the telegram stamped accordingly. That, if the proposal now before Parliament to introduce into the postal telegraph system the innovation of reckoning addresses as chargeable portions of a telegram be carried, two things will assuredly happen—we shall lose the benefit of our present admirably-simple, 20-word shilling tariff, and our chances of surprising all but business friends with a real, actual 'sixpenny' telegram will closely approach the proportion of three to 100."

"J. H. B.," thinks that as it is the present practice of the Post Office to charge each figure in a telegram as one word, under the intended change as regards the charge for addresses, some approach to the Continentel mode of charge for figures (five in a group as one word) should be made, or addresses on telegrams to large towns, where the numbering of houses frequently runs into three figures, will become the most expensive part of the sixpenny telegram.

"Compromise" proposes to issue telegram forms with heading only for recipient, and let this be free, allowing sender to designate him or her self in body of message. This would be in assimilation of rule with halfpenny cards, where address of recipient only is permitted on address side.

In a further letter to *The Times* on the 9th inst., "J. H. B." says:—"The arguments of the Post Office in favour of its persistence to depart from free addresses on telegrams are not such as can commend themselves to a practical business country, to whom it is all important to have a simple, uniform principle which encourages no dangerous risks of telegrams being delayed, or, worse still, not delivered at all by reason of imperfect addresses. Senders of telegrams, I believe, most usually only give their own and their correspondent's address, as they would in ordinary letter writing, so that the person addressed may, if need be, at once and without further reference, know where to telegraph or to write in return. Surely the common sense of the responsible chief of the Post Office now sees how strongly the public condemn any change which might endanger the usefulness as well as too rigorously and too dangerously limit the free and full use of what is next to written correspondence, and which is sure to become more and more, under wise and liberal arrangements, a success undreamt of, as it is already a marvel of almost instantaneous intercourse throughout the entire country. The letter of mine advocating free addresses and one uniform tariff of one halfpenny on every word in the body of all telegrams, seems, so far as I have been able to judge, to meet general approval. The safety, usefulness, and simplicity of such a tariff, encouraging free and full expression at small cost, are apparent and likely to benefit and expand the revenue to an extent which neither the ordinary Post Office nor Treasury official has yet dared to dream of."

The *Daily News* states that it is the intention of the Postmaster-General to entirely remodel the printed telegram form. It will probably be, on and after the 1st of August next, something similar to the forms in use upon the Continent, and in which the sender's name will come as a signature to the message with space for his address if he deems it necessary and is willing to pay for it.

Business.—Mr. A. A. Goldston notifies that he has taken over the whole of the plant of the Hammond Electric Light and Power Supply Company in Middlesborough and the surrounding district, and is prepared to give estimates for all kinds of electrical work.

NOTES.

THE NILE EXPEDITION.—Dal, or Sarkamatto, has been made a telegraph station, and the head-quarters of the line of communication.

THE TASMANIAN TELEGRAPHS.—New post and telegraph offices are about to be erected in Launceston, the estimated cost being about £15,000.

THE BRITISH ELECTRIC LIGHT COMPANY.—A petition for the winding up of the British Electric Light Company is to be heard this day (Saturday).

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 10th April amounted to £3,081.

THE TELEPHONE AND MINES.—In connection with exploring work at the ill-fated Usworth Colliery, the telephone rendered some very valuable assistance.

NEW CABLE.—Telegraphic communication with the Isle of Man is shortly to be improved by the laying of a new and larger cable from Ramsey Bay to St. Bees Head.

ELECTRICAL ATTRACTION.—Some experiments recently made in France show the accumulation of minute particles of dust, &c., on electric light wires to be the result of electrical attraction.

THE ELECTRIC LIGHT IN THE SOUDAN.—The *Daily Telegraph* says:—The electric light has been brought to bear upon the railway works, which will be carried on by night henceforth.

THE ELECTRIC LIGHTING ACT.—Mr. Chamberlain, questioned by Mr. Stanhope, on Monday night, said he did not propose to introduce any Bill this Session to amend the Electric Lighting Act.

CODE TELEGRAMS TO CHINA.—The Imperial Chinese Telegraph Administration notifies that private telegrams written in code are again accepted on the Chinese land lines (Pekin, Tientsin, Hankow, Swatow, Canton, &c.)

THE GREAT NORTHERN TELEGRAPH COMPANY.—This company notify that a telegraph station has been opened at Newchwang, China. Telegrams for that place are now accepted for transmission at the rate of 10s. per word.

AN ELECTRIC MAT.—The Applegate electric mat, covered by an ordinary rug, is a desirable burglar alarm, as the slightest pressure upon it has the effect of ringing an electric bell, and so of calling attention to any nocturnal visitors.

THE ROYAL VISIT TO IRELAND.—On the night of the 15th inst., the ships of the Channel Squadron at Cork were brilliantly illuminated with the electric light, all the merchant vessels and yachts in port also making effective display.

ELECTRIC TRAMWAYS IN AMERICA.—The East Cleveland-street Railway Company of Cleveland, O., is completing arrangements for running the cars of the Euclid-avenue, Cedar-avenue and Garden-street lines with electricity, on the Knight-Bentley system.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 10th inst. were £2,471, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

SALE OF ELECTRICAL APPARATUS.—In our advertisement columns will be found details of the electrical and mechanical plant belonging to the "Pilsen-Joel" and "Electric Lighting Supply and Fitting" Companies, which is about to be sold by public auction.

THE ELECTRIC LIGHT IN FRANCE.—The principal manufacturers in Limoges are now occupying themselves with the question of domestic electric lighting. A committee has been appointed to decide upon the best means to be employed in order to effect their purpose.

THE ELECTRIC LIGHT IN NAPLES.—In connection with the inauguration of the Naples Waterworks on the 23rd inst., we are informed that the waters coming from the Serino will be inaugurated on the 24th, and in the evening the Palace Square and Via Roma will be illuminated by electric light.

NEW CABLE.—A new line of telegraph is being laid between Kirkwall and Tankerness, to be carried direct to Stronsay, thence to Shetland. It is expected that by this new route the cable across Stronsay Firth will have better bottom, and that there will not be such frequent interruptions in future.

CLAIM.—Mr. J. N. Aronson writes to inform us that he patented on the 24th of January, 1882, an incandescent lamp identical with the Perkins lamp described in our issue of the 28th ultimo, and has forwarded us the Patent Office specification. He alleges that the patents of Mr. Perkins date from the latter part of 1883.

THE PROTECTION OF SUBMARINE CABLES.—The Hague correspondent of the *Daily News* telegraphs as follows:—The First Chamber has adopted the International Convention for protecting submarine cables. The Minister for Foreign Affairs promises to do his utmost for the equal protection of cables in territorial waters as in the open sea.

THE LIGHTING OF THE AMERICAN SENATE CHAMBER—The necessary order has not yet been given for lighting the Senate chamber, corridors, and committee rooms by electricity, much to the regret of everybody interested. As the extra session is only for the transaction of executive business, the order cannot be given until Congress re-assembles in December.

THE ANTWERP EXHIBITION.—The Commission of the Antwerp Exhibition will endeavour to establish a unit of price for a unit of work, for each type of machine, and for each kind of application. If this follows as a result of the Exhibition the members of the Commission will be entitled to the thanks of every electrician, and to unlimited kudos at the hands of the public.

THE ELECTRIC LIGHT IN FRANCE—The last installations of the Edison Company are said to be as follow:—New lycée Louis-le-Grand, Paris, 550 lamps; M. Louis Rau, Paris, 40 lamps; Caves de Roquefort (4 installations of 25), 100 lamps; MM. Gillibert et Cie., Marseilles, 200 lamps; M. Schmidt, Havre, 50 lamps; M. Tixerant, Nogent-sur-Seine, 20 lamps; M. Lombard, Arcis-sur-Aube, 50 lamps.

THE INDO-EUROPEAN TELEGRAPH COMPANY.—The directors of this company, at their last meeting, determined, subject to audit, to recommend the payment of a dividend for the six months ended December 31, 1884, of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 10s. per share, both free of income tax, making in all 8 per cent for the year.

ELECTRICITY AND WARFARE.—It has been determined by the Admiralty that not only the armour-plated ships, but the whole of the other vessels to be despatched from Chatham

Digitized by Google

shall be supplied with electrical arrangements for discharging the machine and other guns. All the turret armour-plated vessels, as well as some of the largest of the other ships, will have the electric light fitted on board before they leave Chatham.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—The next ordinary general meeting of this society will be held at the Institution of Civil Engineers, on Thursday, April 23, at 8 p.m., when a discussion on Prof. Oliver Lodge's paper on "The Seat of Electromotive Force in a Voltaic Cell," will take place, and a paper on "Electrical Definitions, Nomenclature, and Notation," by Andrew Jamieson, F.R.S.E., member, will be read.

THE GREAT NORTHERN TELEGRAPH COMPANY OF COPENHAGEN.—The total receipts of this company last year, including the balance brought down, were £324,662 1s. 3d., and the expenses, including debenture interest and amortisation, £112,657 9s. 6d. Out of the surplus, dividends of 5 per cent. and 3 per cent. respectively have been paid, absorbing £120,833 6s. 8d.; £55,555 11s. 1d. is added to the reserve and renewal fund, and the sum of £31,337 18s. 5d. is carried forward.

NEW PROPRIETARY.—A prospectus is issued of the Varley Electric Patents Proprietary, with a capital of £40,000, of which £12,500 are allotted in the form of fully paid-up shares to the vendors. In addition to this, £4,560 in debentures not bearing interest, but falling due for payment at intervals over a period of six years, have been issued in payment for plant and stock. The patents relate to rigid and flexible carbons, storage and regenerative batteries, electric meters, dynamos, and arc and incandescent lamps, electro-chemical, and other filters, &c.

SIXPENNY TELEGRAMS.—Mr. Stuart-Wortley, M.P., on the second reading of the Telegraph Acts Amendment Bill, will move, that "A State Department, enjoying a monopoly of inland telegraphic communication, and liable practically to no penalty for the misdelivery of messages, is not, in the opinion of this House, justified in proposing to so adjust its tariff as to discourage the full statement of all particulars reasonably necessary for the identification of the persons to whom, and the place at which, it contracts to deliver the messages which it receives for transmission."

ELECTRIC LIGHTING IN THE NAVY.—In addition to the gunboats mentioned last week as being supplied with the machinery requisite for producing electric light, the following ships have also to be furnished with dynamos and engines for this purpose, viz.—H.M.S. "Orion," fitting at Deptford, H.M.S. "Inconstant," fitting at Devonport, "H.M.S. "Nelson," "Rupert," and "Invincible," fitting at Portsmouth. The Victoria dynamos for the above ships are being actively pressed forward by the Anglo-American Brush Electric Light Corporation, to whom the contract for the work has been entrusted by the Admiralty.

ELECTRIC LIGHTING AT LEEDS.—At a recent meeting of the Leeds Town Council, the chairman of the Electric Lighting Committee, in moving the confirmation of the minutes, stated that the committee had been very badly treated by the contractors, and that their case would be disclosed in a court of law. The town clerk, replying to a question, said he had that morning been served with a writ on behalf of the Corporation. The contractors sought to recover a balance which they allege to be due; but as this now formed the subject of litigation, it would not be advisable to make any remarks upon the facts.

PROGRESS IN GERMANY.—During the past six years dynamos to the number of 6,000 have been constructed in the different workshops in Germany, representing a value of £700,000. The number of arc lamps made during the same period was 20,000, realising £250,000. In the four years, 1880 to 1884, the number of telegraph offices open to the public rose from 5,114 to 7,529, and the mileage of the wires from 121,520 to 150,040 miles. The telephone was introduced into Germany in 1880; there are to-day 58 country exchanges, having 7,311 subscribers, and possessing a network of wires extending over a distance of 10,100 miles.

THE ELECTRIC LIGHT AT WASHINGTON, U.S.A.—The United States Electric Light Company have put up eight of their arc lights in front of the executive mansion at Washington, U.S.A. The wires were laid in underground cables, and led up through the posts so as to be entirely invisible. The effect was excellent, and afforded so much satisfaction that an order has been given for a continuance of the lighting in place of the gas lamps by which the approaches to the mansion have been lighted. The incandescent lights for the interior department have been put in by this company, and also give much satisfaction.

THE BREAKDOWN OF H.M.S. "MONARCH."—When it became evident that this ship could not make Malta without a serious accident to her machinery, it was decided, we are informed, to stop the engines and await arrival of a passing steamer, which might tow or render other assistance, the distance from Malta being about 250 miles. Although the "Monarch" burnt the electric light at her masthead and sent up rockets all night, it was not until the following day that she was sighted by the steamship "Hampshire." Had it not been for the valuable assistance of the electric light the succour of which she was in need might have been still further delayed.

SIMULTANEOUS TELEPHONY AND TELEGRAPHY.—The French Minister of Posts and Telegraphs has lately organised a series of experiments of simultaneous telegraphy and telephony upon the subterranean cables which connect Beauvais with Paris. The distance is about 100 kilometres (62 miles), and the results are said to have been in every way satisfactory. The apparatus employed during the experiments was that of M. Louis Maiche. These experiments, says our contemporary *Cosmos*, are of great importance from the fact that they are the first which have been made, subsequent to those between Paris and Versailles, Paris and Morat, Paris and Meaux, upon subterranean cables of such a length.

THE CENTRAL ASIAN TELEGRAPH.—Mr. Charles Marvin learns from the semi-official *Karkaz* of Tiflis particulars of the laying of the Central Asian telegraph. At the present moment the telegraph from Askabad to Merv, *via* Sarakhs, is already constructed and in full working order. Consequently, the telegraph extends from St. Petersburg to Merv, from whence couriers could carry messages to General Komaroff in less than a day. In regard to this subject we may mention that four months ago, namely, in our issue of the 10th of January, we announced the contemplated immediate erection of a line of telegraph from Askabad to Merv and Sarakhs, and the week following, the *Standard's* Teheran correspondent telegraphed that the Russians were then erecting the line from Askabad to Merv.

THE BIDWELL ELECTRIC RAILWAY.—The officers of the Bidwell Electric Railway Company have given an exhibition

Digitized by Google

of their new motor at Philadelphia, U.S.A. A track was laid around the room 250ft. in length, and a car capable of holding 10 persons was placed upon it. The motive power was furnished by a 5 horse-power dynamo. This also furnished several incandescent lamps in the car, and some large lights along the track. The same current also heats the car. By an arrangement which is attached to the car, salt or a chemical compound can be fed to the track in cold weather to keep it clear of ice or snow, and dirt is swept out by a brush which is also attached. The experiments are said to have been "quite successful." We should think so, indeed. But why does not it also get up steam and heat its own boiler?

SIXPENNY TELEGRAMS.—Lord J. Manners gave notice on Monday night that, on the second reading of the Telegraph Acts Amendment Bill, he would move "That in the opinion of this House it is expedient in any arrangement of the charges for the transmission of inland telegrams to retain the system of free addresses which was established by the Telegraphs Act." The *Standard* states that there is every probability that Lord John Manners' Amendment will be carried. In that event the Postmaster-General will abandon the Bill, and the introduction of cheap telegrams will be postponed for a year. As the sixpenny telegrams would have involved a considerable sacrifice of revenue, the Chancellor of the Exchequer will not, under present circumstances, regret the postponement of their introducfion for twelve months.

ELECTRIC LIGHTING OF A DINNER TABLE.—A correspondent informs us that at the Highland and Agricultural Society's Spring Flower Show held in Edinburgh last week there was a unique display of electric lighting of a dinner table *a la Russe* by Messrs. Jenkinson, of Princes-street. The candelabra and centre piece, being of china from which the lamps hung, decorated with flowers, presented a very artistic appearance. Round the table at intervals were growing plants, with a glow lamp in the centre of each, which produced quite a novel effect. The whole presented a fairy-like *coup d' oeil*. All wire on the table was completely hidden by green foliage. The current was supplied from accumulators underneath the table. The ornaments were specially manufactured for use with the electric light, the whole of the arrangements being carried out by Mr. James Gibson, of Edinburgh.

THE OVERHEAD WIRES COMMITTEE.—On Thursday the Select Committee of the House of Commons, under the presidency of Mr. G. W. Russell, to inquire into the law controlling telephone and telegraph wires, resumed its sitting for the first time after the Easter recess. Mr. Johnson, the chairman of the Commissioners of Sewers, was first examined. He said that, if it were possible, all the wires should be put underground, but the difficulties were very great, if not insurmountable, especially in the matter of expense. That might be met in the first place by loan, so that the cost of subways might be met. He did not advocate this, but he thought the companies might recoup themselves by rentals. If all the directions were given in an Act of Parliament there would be no difficulty in local authorities controlling the wires. There should, he thought, be an appeal to a department of the Government.

THE ELECTRIC LIGHTING ACT.—Commenting upon this question, the *Pall Mall Gazette* says:—"There is to be no Electric Lighting Amendment Bill this year, and for the very good reason that Parliament has already quite as much as it can do in the few months that remain to it. The Committee of Electric Lighting Companies, in the draft Amendment Bill which they have submitted to Mr. Chamberlain, have raised some knotty questions, which, in the interest of the public, should not be settled hastily by a moribund Parliament. Broadly, there is not an important clause in the Electric Lighting Act the reconstruction of which has not been very fairly demanded by electricians, and the ultimate settlement of the question will probably be arrived at by steering a middle course between the Act and the draft Amendment Bill. Meanwhile, electricians may very profitably devote their best energies to the invention of a serviceable meter."

PREPARING FOR WAR.—Additional supplies of torpedoes are being sent to the naval stations at home and abroad, and also to the officers in charge of the coast districts. These torpedoes are of the stationary or submarine order, to be used for the defence of harbours and the entrances of rivers, and fired by electricity from the shore, to which, when touched by a passing vessel, they transmit automatically a vibratory signal. To this class, and the Whitehead, or fish torpedo, it is proposed to add a third, being a newly-designed electric torpedo, which is easily steered by electricity from the shore, and travels in the shape of a submerged boat to the attack of a hostile ship a mile or more away. Experiments are now being made with this torpedo, under the direction of the inventor, at one of the dockyards, and some marvellous results have been obtained; but, like other torpedoes which are allowed a certain freedom of action, this one has exhibited an unfortunate disposition to plunge downwards into the mud. Provision is now being made to counteract this tendency, and the electric torpedo is undoubtedly destined to be one of the most dreaded of its family.

OUR TELEGRAPHIC COMMUNICATION WITH THE EAST.—The following resolution has been passed by the Council of the London Chamber of Commerce and forwarded to Her Majesty's Secretaries of State for Foreign Affairs and the Colonies, and the Chancellor of the Exchequer:—"That, in view of the great inportance of British mercantile interests in the East, more particularly as concentrated at Hong Kong—the shipping tonnage of which entered and cleared in 1883 amounted to 6,882,000 tons, the yearly imports and exports exceeding £4,000,000 sterling—strong representations be made to the Government as to the imperative necessity of protecting British interests in the China Seas by adequate defensive precautions both at Hong Kong and Singapore; and that these two important ports should be without delay united by a direct submarine telegraph cable entirely in British hands, even if a small Imperial subsidy (as in other cases) be requisite to ensure its being laid." This action was taken on receipt of a telegraphic communication from Hong Kong notifying the decision of the Legislative Council in the same direction, and urging the London Chamber to support.

A DARING ACT.—A daring act was performed recently (says the Melbourne *Age*) at Griffith's Point by a telegraph line repairer named Charles Sharp. The telegraph wire which crosses the eastern entrance to Western Port Bay is fixed on two tall poles 160ft. in height. At the base they are 9ft. in diameter; hence it is impossible to climb to the top by the ordinary method. An iron pulley was, therefore, fitted to the poles 110ft. from the ground. By means of a wire running through the pulley a person could be raised to a point where the diameter was small enough to allow a man to clasp it with his arms. The wire broke recently, and Sharp essayed to climb the pole with a new wire and reeve it through the pulley. He fixed two long sharp spikes to his feet and commenced his perilous ascent, which was made by forcing one spike into the pole and raising the other leg a step higher. Owing to the immense girth of the pole he was, however,

Digitized by Google

unable to get a good hold. Notwithstanding this he reached the pulley and descended by means of the wire he had carried up. Had Sharp lost his presence of mind for one moment he would have been dashed to pieces on the rocks below.

A NEW CHANDELIER FOR ELECTRIC LIGHTS.—A new chandelier, designed by M. Clariot, has been introduced in the Magasins of the Louvre in Paris, in connection with the Jablochkoff candles employed to light those premises. The apparatus consists of a platform of marble, in the centre of which is disposed a metallic piece communicating on one side with one of the poles of the machine generating the current, and on the other with one of the chandeliers of each pair of candles. The other chandelier carries a small piece of wire fixed to a drop of solder, which latter, upon being fused, fills the office of the commutator. There are four pairs of candles, each pair having a separate metallic piece arranged on the other side of the platform. These pieces are insulated from each other. The small piece of wire is fixed upon the bar of metal carrying each pair of candles in such a manner that by keeping a spring compressed it prevents the candles from being lifted into position and lighted. In that case, only one pair, that in connection with the central plate, can be in action. When, however, it is wished to add to the number, it is only necessary to effect the fusion of the drops of solder, which releasing the spring in each particular instance, put as many pairs of candles as may be desired into circuit.

MOTIVE POWERS.—A correspondent of the Manchester *Examiner* writes as follows:—The proposal to levy a tax upon coal would greatly injure many dependent industries, without creating other industries. I think two very important uses to which coal has been put may now be supplied from other sources. We have it now in our power to dispense with coal for motive power and lighting purposes. The electric light may now supplant gas light, and motive power may be had from electricity in running our mills and workshops. In fact there is now no necessity for coal except for heating purposes. We have a large storage of power in our reservoirs which can be illimitably increased. I would suggest that an exhibition of water motive power and electricity be held in Manchester, and also that diagrams of the country be exhibited showing the best watersheds where water can be extensively stored. I have often desired to utilise the town's water for the purpose of turning machinery by a water engine, but I am prohibited through the excessive charges. I have often inquired if there were any exhibitions of water and electric motive power, but no one knows. I hope our Manchester friends will get up an exhibition, which I am sure will be largely patronised. It will create other industries and utilise an inexhaustive source of power.

ELECTRICITY AND MINES.—The mines of Marles, near Béthune (Pas-de-Calais), offer an example of the numerous applications to which electricity readily lends itself. The mines are not only lighted by the fluid, they possess a telephone system, an electric signalling apparatus, and other equally useful installations. The lighting is effected by 60 Edison incandescent lamps in the buildings and offices, and four arc lamps, of 32 candle-power, placed at the shafts. The signalling apparatus is at the bottom of the mine, and replaces the ancient system of communication by cords or rods, which were uncertain and irregular in their action. The different telephone stations, numbering three to each shaft, are connected by a network of conductors, arranged in such a manner that the signal assures the sender of the faithful transmission of his call. This signal is given by a needle which indicates upon a graduated dial the nature of the signal given, while attention is called by a bell of the ordinary pattern. These arrangements are said to so economise time that ten tons of material can be raised in excess of that found to be possible with the old system. In order to ensure the proper working of the ventilators in the subterranean passages there is also an electric tell-tale, which shows the number of revolutions made by each fan in a given time. The whole of the installations have been put down by Breguet, under the direction of M. Thiry, the chief engineer of the company.

ELECTRIC LIGHTING OF THE "ANGELO."—This fine steamer, of the Wilson line, regularly engaged in the mail and passenger service between Hull and Christiania, was on Tuesday taken down the Humber for a trial run, having recently undergone very extensive improvements. One of the greatest improvements effected from the passenger's point of view will be the introduction of the electric light. In every part of the vessel, including the masthead and side lights, this modern means of lighting has been introduced. Altogether there are 120 lights, eight of which are in the dining saloon, which is amidships on deck, whilst the drawing room saloon is also fully lighted. From stem to stern the 'tween decks are lighted for the accommodation of the emigrants, and the same kind of lighting has been supplied for the engine room, and even the stoke hole. The fittings have been placed on board by Mr. T. Muse, who has been engaged by Messrs. Thomas Wilson, Sons, and Co., as their electrical engineer. Electricity is generated by one of Paterson and Cooper's Phœnix dynamo machines, and the lamps are the Edison-Swan. The masthead and side lights are fitted with the Bernstein incandescent lamp. The engine to drive the dynamo has been supplied by Messrs. Rose, Downs, and Thompson, and it has been fixed on the first platform of the engine room. Motive power is supplied from the main boilers when at sea, and by the donkey boiler when in harbour. The masthead and side lights have been designed by Mr. Muse, and manufactured by Messrs. Whitfield and Hakes, Commercial-road, Hull. All the fittings have been made locally by Messrs. J. Clark and Son or by Messrs. Whitfield and Hakes.

AFRICAN CABLES.—We notice with considerable surprise that a meeting has been held, under the presidency of Baron Grant, as a public protest against interruptions of the cable service to South Africa. It may be taken for granted that the promoters of this meeting imagine that all communication is intended for their own special benefit, and also that the various natural forces at the bottom of the sea can be rendered nugatory so far as the cable they specially desire to use is concerned. Those, however, who have had experience in cable matters know that however careful survey has been, it is absolutely impossible to guarantee that the cable is laid in harmless waters. One section of the South African cable has been rendered useless from time to time from natural causes which no experience, no amount of expenditure, no constant scrutiny could ward off. The company owning this cable has long since decided to duplicate this particular section, and to thus endeavour to obviate this rupture of communication. The cable for this work is, we believe, almost wholly manufactured, and the duplicate section will be on its way to the coast of Africa in a few days. What Baron Grant and his co-agitators can expect of a commercial company it is difficult for us to say. In the first place, the directors of such a company have to provide interest upon the capital entrusted to them by the shareholders, and in order to do this they cannot undertake the duplication of cables unless it is absolutely necessary, or unless the business transacted is sufficient

Digitized by Google

to warrant the expenditure. It is an easy thing to say cables ought to be kept in thorough repair, but those who have the control of the cables know that it is extremely difficult to keep them so.

THE ELECTRIC LIGHT AND THE SUEZ CANAL COMMISSION.—The *Standard* is informed that at the last meeting of the Grand Technical Commission one of the members observed that the sub-commission that had been charged to go to the Isthmus of Suez to study on the spot the improvements required had not in its report made any mention of the navigation of the canal at night by means of the electric light. This question was, he knew, under serious consideration, and he thought it right that in the report of the proceedings of the commission mention should be made of this important question of night navigation, which was calculated, when realised, to so materially shorten the time passed by most ships in the canal. The answer given in the name of the sub-commission was that it had only wished to declare that, in accord with the opinion of the captains and pilots, a vessel, even when obliged to spend a night in the canal, would, when the improvement works were completed, get through the canal in 24 hours. The sub-commission had not been charged to study the subject of lighting, but it had, nevertheless, witnessed experiments of night navigation of the canal by means of the electric light, established on a tug steamer. The experiments took place on the canal, between Suez and Ismailia, and their result is given in the report in the following words :—"Unfortunately, the experiment was made on a moonlight night—that is to say, the effect of the electric light was attenuated. On the portion of the canal where it was made, comprising the few miles which precede the arrival at Lake Timsah, the navigable channel is buoyed with pairs of buoys (one red and one black) at intervals of 500 metres. The electric light always enabled one pair of buoys to be kept in sight, but it was scarcely before the tug had arrived at a pair of buoys that another pair became distinctly visible ahead. Under the conditions in which the experiment was made it would have been necessary to have pairs of buoys placed at half their present distance from one another, as for steering it is requisite always to have two pairs in sight."

OVERHEAD WIRES.—A correspondent of the *Pall Mall Gazette*, writes as follows :—"I am credibly informed that between 150 and 200 overhead wires broke in London during the last slight snowstorm. Had the snow frozen as it fell, not a galvanized wire in London would have been left hanging. What loss to life and property this means may be gathered from the fact that one company stated in a law case some time back that it had 10,000 miles of overhead wires in London alone. In a storm in Aberdeen last month the telephone system was much interfered with, and the papers say that wires were dangling in all directions. At Portsmouth the other Sunday the snow broke numbers of wires and snapped some of the iron telephone posts. At Notting-hill the weight of the snow drove an iron telephone 'chair,' or support for several wires, through the roof of a house. Some years ago a wire in falling decapitated a horse in Oxford-street, and another killed a man in Manchester. At a fire in Oldham an escape 36ft. high caught in some telephone wires, which dislodged a lot of masonry and hurled it among the crowd, seriously injuring several persons. Notwithstanding such occurrences the United Telephone Company is at present applying to Parliament for compulsory powers to suspend overhead wires within 3ft. of roofs, or 15ft. of the surface of roads, without the consent of those interested or any compensation to them, either for the original invasion of their rights of property or for the loss they may suffer through the wires falling in storms. Telephonic communication is in its infancy and will increase a hundredfold. It is absolutely essential in the public interest that the wires should be carried underground. The cost is a matter for the telephone companies, but as the subscription in London to their exchanges is three or four times as much as in many large cities, they could probably well afford the expenditure. The wires are carried in the sewers in Paris." This statement, as far as it relates to the number of wires broken and injury done, has since been contradicted. The communication, however, remains substantially as given.

SUGAR REFINING BY ELECTRICITY.—Some further particulars of this remarkable process of sugar refining appear in our contemporary, the *Grocer*. For the exploitation of the scheme a new company has been formed, with a capital of 1,000,000dols. This undertaking is entitled the "Electric Sugar Refining Company," their offices being at 47, King William-street, New York. Mr. R. N. Woodworth is the president, and Mr. H. Belden, of the National Park Bank, New York, is the secretary. The system of manufacture is supposed to be a profound secret, the only persons now engaged in carrying out the invention being at work with closed doors, and nothing on a large scale will be attempted until all the arrangements are completed. The company, it is said, owns the invention of Henry C. Friend, of New York, and its exclusive use for the whole world. This invention is an entirely new process of refining sugars; it is dry throughout, dispensing altogether with boiling and the use of bone-black. No syrup whatever is produced, but the whole product is hard sugar of nearly, if not quite, absolute purity, namely, 100 per cent. cane sugar, as per analysis. A principal feature of the process is the use of electricity, concerning which the inventor claims he has discovered a new manner of producing it at a nominal cost. He claims, and is said to have proved, the following points (the demonstrations he has made have been with parcels of sugar from 10lb. in weight up to over 2,300lb., and the qualities of the raw sugars refined have been various, including beetroot, second quality, Java stroops, and such low grades) :—The process of conversion does not take, in point of time, more than four hours; and the production once commenced, the output of the refined sugar is continuous so long as the raw material is supplied. The cost of the process will not exceed 80 cents per ton—this being the price arranged by contract with Professor Friend, to the performance of which he pledges all his interest in the company; and the product upon analysis will show not less than 99·50 per cent. of pure sugar. Any description of refined sugar can be produced, from the finest powdered up to and including cut and pressed loaf; and the profit in the working of this process will be not less than £5 per ton of 2,240lb. The cost of the machinery required to produce at the rate of 4,000 barrels of refined sugar per day of twenty-four working hours, together with the power requisite to run the machinery, and all the attendant apparatus for handling it up to the point of its being put into barrels, and the fitting of a suitable building to receive and work the machinery, is estimated not to exceed £20,000. This discovery in sugar refining has naturally aroused a deal of curiosity and inquiry. Already three members of well-known firms of sugar refiners at Liverpool have, we are informed, started for New York to inquire specially into the whole matter on the spot, and bring back here authentic and trustworthy reports of the entire scheme.

ALTERNATING CURRENTS.

BY THOMAS H. BLAKESLEY, M.A., M. INST. C.E.

(CONTINUED FROM PAGE 412.)

The cases already considered of a circuit bridged over at one or more pairs of points by condensers have not included the more complicated systems in which self-induction exists in any of the sections of the conductor. In practice a coefficient of self-induction would always exist in the section including the generator, and might be introduced into any of the other sections with the instruments inserted into them. It is therefore desirable to know what effect it would have upon the currents of the system. The general case may be represented by the following:—

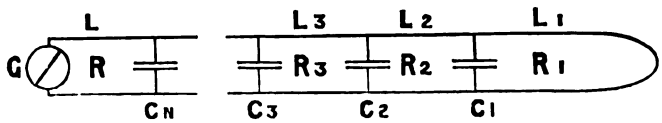

FIG. 10.

Here $C_1, C_2, C_3, \ldots C_n$, represent the capacities of the condensers, beginning from the remote end of the circuit,

$R_1, R_2, R_3, \ldots R_n$, R, the resistances of the sections.

$L_1, L_2, L_3, \ldots L_n$, L, the coefficients of self-induction of the sections, in the same order.

G represents the generator of the harmonically varying E.M.F.

Let T be half the period as usual.

To construct the proper diagram of electromotive forces, proceed as follows:—

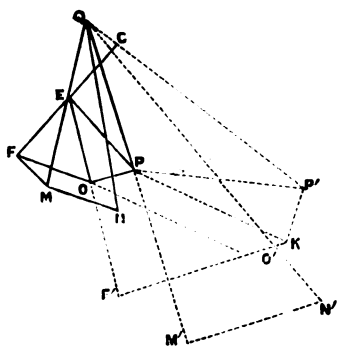

FIG. 11.

Take any line E C to represent the effective E.M.F. in the section R_1.

Set off the angle C E Q in the direction of advancement, such that $\tan CEQ = \frac{L_1 \pi}{T R_1}$, and draw C Q perpendicular to E C.

Produce Q E to M, so that, Q E : E M :: R_1 : R_2.

At Q set off the angle M Q N in the direction of advancement, such that $\tan MQN = \frac{C_1 \pi R_1 R_2}{T R_1 + R_2}$, and draw M N at right angles to Q M.

Draw M F at right angles to C E produced, and cutting it in F, thus making the two triangles, C E Q, F E M, similar.

From F draw F O parallel and equal to M N, and in the same direction as that line.

Join O E, and at E set off the angle O E P in the direction of advancement, such that $\tan OEP = \frac{L_2 \pi}{T R_2}$; draw O P perpendicular to E O, and join P Q.

Then P Q is the E.M.F. of the condenser C_2, or if there be but one condenser, it will be the E.M.F. of the generator.

E Q is the E.M.F. of the condenser C_1,

O E is the effective E M.F. in the section R_2,

and E C, by hypothesis, that in the section R_1.

These points are proved as follows:—

Since E C is the effective E.M.F. in R_1, which possesses a coefficient of self-induction L_1, the impressed E.M.F. of this section must be such an E.M.F. as has its phase and magnitude determined as E Q has been obtained from E C, *i.e.*, it must be the hypothenuse of a right-angled triangle having the effective E.M.F. for a base, and the angle between the base and hypothenuse such that its tangent is equal to $\frac{L_1 \pi}{T R_1}$, and this angle must be in the direction of advancement from the base.

Hence E Q is the E.M.F. of the condenser C_1.

Since Q E : E M :: R_1 : R_2, and the angle M Q N has for its tangent, $\frac{C_1 \pi R_1 R_2}{T R_1 + R_2}$,

and $NM = QM \cdot \tan MQN$,

therefore $NM = QM \cdot \frac{C_1 \pi R_1 R_2}{T R_1 + R_2}$.

Hence $\frac{NM}{R_2} = C_1 \pi \cdot \frac{R_1}{T R_1 + R_2} \cdot QM \cdot = \frac{C_1 \pi}{T} \cdot QE$,

and N M is at right angles to Q E;

therefore $\frac{NM}{R_2}$ is the charging current of the condenser C_1, or N M is the E.M.F. which, acting through the resistance R_2, would produce the charging current for that condenser; and N M = O F. Hence $\frac{OF}{R_2}$ is the charging current. But $\frac{EC}{R_1}$ is the current in R_1 discharging the condenser in that section, and $\frac{EC}{R_1} = \frac{FE}{R_2}$.

Hence $\frac{EF}{R_2}$ is that current considered as one of the two components of the charging current $\frac{OF}{R_2}$.

Therefore $\frac{OE}{R_2}$ is the other component, *i.e.*, O E is the effective E.M.F. in the section R_2.

But this section has a coefficient of self-induction L_2, and $\tan OEP = \frac{L_2 \pi}{T R_2}$.

Therefore P E is the impressed E.M.F. necessary to produce the effective E.M.F. O E in this section.

But the impressed E.M.F. in R_2 is the resultant of the two E.M.F.'s of the condensers C_2 and C_1, and E Q is the E.M.F. of the condenser C_1.

Therefore, finally, P Q is the E.M.F. of the condenser C_2, or, if there be but one condenser, C_1, P Q is the E.M.F. of the generator.

The extension of the diagram to give the E.M.F.'s involved in the next section, R_3, will be easily understood if the steps are merely indicated, as follows:—

$$QM' : QP :: R_3 + R_2 : R_2,$$

$$\tan M'QN' = \frac{C_2 \pi R_2 R_3}{T R_2 + R_3}, \quad QM'N' = \frac{\pi}{2},$$

$$OF' : EO :: R_3 : R_2,$$

F' O' is equal and parallel to M' N',

O' K is equal and parallel to O P,

$$\tan KPP' = \frac{L_3 \pi}{T R_3}, \qquad PKP' = \frac{\pi}{2}.$$

Then P' Q is the E.M.F. of the condenser C_3, or, if there be but two condensers, of the generator, and K P is the effective E.M.F. in R_3, *i.e.*, $\frac{KP}{R_3}$ is the current in the section R_3.

Again, from the two lines P' Q, K P, with a further knowledge merely of the resistance and coefficient of self-induction of the next section R_4, we can deduce the current in that section and the E.M.F. of the generator or condenser C_4, as the case may be. Thus a complete diagram may be made showing the phases and magnitudes of every E.M.F. involved.

On contemplating Fig. 11, there is one important point to be noticed, viz., that self-induction in the sections by no means

Digitized by Google

necessarily diminishes the currents in them, but up to a certain point may be actually beneficial. This cannot be the case when there is no capacity in circuit. Under such circumstances the self-induction must invariably diminish the current produced by a fixed electromotive force, but when condensers exist, it may happen that a smaller E.M.F. in the generator will produce a given heating effect in the sections of the circuit, by virtue of the self-induction in the sections, than would have been required had there been no self-induction.

In the diagram, Q O would have been the position of the line representing the E.M.F. of the condenser C_2 had there been no self-induction in the section R_2. As there is a coefficient of self-induction L_2 attaching to this section, the line of E.M.F. of the condenser C_2 takes the position Q P. Now O P is merely drawn at right angles to O E, and such that $OP = OE \frac{L_2 \pi}{T R_2}$. It is clear, therefore, that when the angle Q E O is less than 180°, a certain amount of self-induction will make Q P smaller. This will be the case until Q P O is a right angle, after which an increase in the coefficient of self-induction will necessitate a larger impressed E.M.F. to produce the given effect.

Similarly if Q P K is less than 180°, Q P′ may be diminished by increasing L_3 up to the point when Q P′ K is a right angle.

When Q P′ is at a minimum, and therefore at right angles to K P′, it is parallel to P K. In other words the phase of the impressed E.M.F. coincides with that of the current in the generating section. And similarly, for every section the E.M.F. of the condenser C_m would be a minimum when its phase corresponds to that of the current in R_m, a condition settled by the proper finite value being given to L_m.

An important case is that in which a generator operates in a circuit which is only closed by a condenser. If the condenser is a leaky one, the resistance through the leak is that represented by R_1, the remainder of the circuit is represented by R_2, for which there is a coefficient of self-induction L_2. Here L_1 is zero, and therefore in Fig. 11 the angle Q E C will be zero, or Q will coincide with C, F with M, and O with N, and the diagram is reduced to Fig. 12.

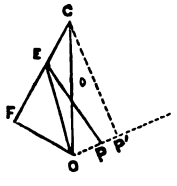

Fig. 12.

When there is no self-induction, the impressed E.M.F. for given effective E.M.F.'s in the two circuits is C O; but as L_2 increases from zero the impressed E.M.F. necessary becomes smaller, as C P, where $\tan P E O = \frac{L_2 \pi}{T R_2}$. This goes on until P arrives at P′, when the angle C P′ O is a right angle, at which point the impressed E.M.F. is a minimum. The condition that this shall be the case is easily deduced from the geometry of the figure, and is expressed by the equation

$$\frac{T^2}{\pi^2 C}\left\{\frac{1}{L_2}-\frac{1}{C R_1^2}\right\}=1 \quad . \quad . \quad . \quad . \quad . \quad (\alpha)$$

which shows it to be independent of R_2, or the resistance in the section including the generator. From the above the proper value for L_2 may be deduced. It may, however, be observed, that as long as L_2 approached the value indicated by this equation, all practical advantage will be gained, because, C P′ O being a right angle, a variation in the value of the angle O E P′ will only affect the length of C P′ infinitesimally.

The proportion in which the presence of the beneficial coefficient of self-induction renders it possible to reduce the impressed E.M.F. is the relation which C P′ bears to C O. This relation is expressed by the fraction

$$\frac{R_1 \sin^2 \alpha + R_2}{\sqrt{(R_1+R_2)^2 \sin^2 \alpha + R_2^2 \cos^2 \alpha}},$$

where α is the angle O C E, *i.e.*, is the angle whose tangent is equal to $\frac{C \pi R_1 R_2}{T R_1 + R_2}$.

The case is still simpler where the condenser is not a leaky one. In this case R_1 is infinite, and in Fig. 12 the point E coincides with F, and the line O E is coincident with the line O F, so that O P, which has to be at right angles to O E, becomes parallel to C F, the circumstances being simply represented by Fig. 13.

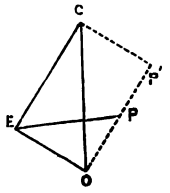

Fig. 13.

From this figure it is evident that when the self-induction coefficient is of the proper magnitude to allow the impressed E.M.F. to be a minimum, as represented by C P′, then this E.M.F. will also be the value of the effective E.M.F. in the circuit, represented by O E.

The tangent of O C E is $\frac{C \pi R_2}{T}$, which is the value of $\frac{C \pi R_1 R_2}{T \,.\, R_1 + R_2}$, when R_1 is made infinite, and the tangent of P E O is $\frac{L \pi}{T R_2}$.

But when P moves to P′ these angles become complementary to each other; that is, the tangent of one of them is equal to the inverse of the tangent of the other.

Hence this condition is expressed by the equation

$$\frac{C \pi R_2}{T} = \frac{T R_2}{L \pi},$$

whence $T = \pi \sqrt{C L}$ . . . . . (β)

R_2 disappearing from the equation.

This condition can also be deduced at once from the equation (α) by putting R_1 = infinity.

The result may be summed up in the following words:—When an alternating generator operates upon a circuit which is closed by a condenser without leakage, and which possesses a coefficient of self-induction, then there is a certain period of alternation which may be given to the generator, at which the condenser might be replaced by a junction introducing no additional resistance into the circuit, the coefficient of self-induction being also removed, without disturbing the current. The condenser, in fact, in conjunction with the coefficient of self-induction, will obliterate the effects of the breach of continuity in the conductivity caused by the infinite resistance of the condenser itself. Moreover, this state of things is quite independent of the resistance of the circuit itself, which will then simply regulate the current in the same manner as with continuous uniform electromotive force.

It is to be observed that the advantage gained by establishing the critical relationship between the capacity, the coefficient of self-induction, the period, and the resistance in the remote section, when that is finite, is simply one of diminished potential. It is not one giving greater direct economy, because the power at work will be the same whether that relationship is established or not, since (Fig. 12) the power is equal to $\frac{O E}{2 R_2} \times P C$ multiplied by the cosine of the angle between E O and P C, *i.e.*, the power is equal to $\frac{O E, P' C}{2 R_2}$, even if P does not coincide with P′, and a similar remark may be made in other cases.

EXPERIMENT WITH A SHUNT-WOUND DYNAMO USED AS A MOTOR.

BY GISBERT KAPP.

Some time ago the author had occasion to use a shunt-wound dynamo as receiver in transmitting power electrically, and in doing so he observed a phenomenon which was not only very puzzling, but threatened to make the transmission of power impossible, unless the cause could be discovered and remedied. As similar difficulties might arise in other cases, an account of those experiments will probably be useful to some of the readers of this journal. It is well known that a series-wound dynamo when used as a motor runs in the opposite direction to that in which it has to be driven when used for the generation of a current. To make the machine run in the same direction (call it forward) the coupling up between the brushes and the field coils must be reversed. With a shunt machine this is not required; generally speaking it can be used as a dynamo, or as a motor, without any alteration in the coupling up between the armature and the field. The shunt machine used in the experiments was driven by a current generated by a compound dynamo, the shunt of which was weak as compared to the main coils, and when doing little or no external work it behaved in a most erratic manner, running backward and forward alternately. At every reversal excessive sparking took place at the brushes of both the motor and generator, and it was clear that both machines were overstrained, and would speedily come to grief if the current were left on.

To explain what takes place under these conditions we will start with the assumption that the generator is kept running, and that the motor is switched on whenever power is required. This is the usual practice where motive power is used at intervals for industrial purposes. Since the generator is a compound machine the leads remain charged to the full working potential during the time the motor is not in use, and immediately on switching it on the current is provided with two paths by which it can flow from the positive to the negative lead. The one is through the armature of the motor, and the other through its field coils. As the motor is at rest, there is no counter electromotive force to oppose the flow of current through the armature, and the result is a momentary excess of current. The immediate effect is that the armature is started revolving at a high speed before the field magnets have had time to get excited, for it must be remembered that an armature will revolve in a non-excited field, though with considerable waste of current. The speed required to produce a given counter-electromotive force is the greater the weaker the excitation of the field, and hence the motor starts running at a much higher speed than it would have in regular work. On account of self-induction in the field-magnets, which in a shunt machine is considerable, the magnets require some time to become fully excited, and whilst the strength of the field is growing the armature is gathering speed and storing up mechanical energy. When at last the field magnets are saturated, the speed of the armature is so great that the counter-electromotive force in the motor not only equals but exceeds the potential maintained in the leads by the generating dynamo, and the current is forced back into it. For the time being the motor is transformed into a generator, the energy stored mechanically in the revolving armature of the motor being returned to the circuit in the shape of current. This reverses the polarity of the compound machine (the shunt coils being weak as stated above), and now both the generator and the armature of the motor are working in series, the generator assisting instead of opposing the current started by the motor. At this moment we have the following state of things:—The field magnets of the motor have just attained their maximum of saturation with their original polarity; the polarity of the generator has been reversed, and an excessive current, in an opposite direction to that which produced motion, flows through the armature of the motor. Consequently the armature is quickly brought to rest, and started in the opposite sense (backward) at a high speed. It now opposes a certain counter-electromotive force to the current from the generator, but it is not an increasing force as before, but a decreasing one, because the orignal excitation and polarity of the motor field magnets is gradually vanishing, by reason of the reversal of polarity in the main leads, from which these shunt coils are fed. Just as it took a certain appreciable time (several seconds) for the magnets to become excited, so does it take time for them to lose their magnetism. Eventually there arrives a moment when all the original polarity in these magnets has vanished, and when, therefore, the force impelling the armature to run backward has also ceased, though there is still an excessive current passing through it. A moment later the armature comes to rest, and begins to run forward at a high rate of acceleration, when the whole cycle of phenomena just described is gone through again, but this time starting with a current in reverse direction to the first. The next (third) cycle will start with a current in the same direction as the first, the fourth cycle with a reverse current, and so on until the belt is thrown off the generator, or some other mishap takes place. If the generator is a compound machine, deriving most of its exciting power from the shunt coils, it may be that the mechanical inertia stored in the armature of the motor is not sufficient to reverse the polarity of the generator, and then no difficulty arises; but with a series machine for a generator, or with a compound machine deriving most of its exciting power from the series coils, the phenomena just described are sure to take place, unless some special precautions are taken. The difficulty can be met by keeping the shunt coils of the motor field magnets permanently connected with the main leads, and interrupting only that part of the current which goes through the armature. The switch should also be joined with a rheostat, so as to prevent any excess of current whilst the motor is yet at rest. After the latter has attained its normal speed the resistance of the rheostat may be cut out either automatically by a centrifugal governor or by hand.

But with all these precautions there is still some danger of reversal if the speed of the generator should temporarily slacken, and the best and safest plan is to use the same type of machine for the generator and motor. The experiments just described afford an interesting example of the relation and interaction between self-induction or electro-magnetic inertia and the purely mechanical inertia as represented by the energy stored up in a heavy revolving body.

LOSS OF THE TELEGRAPH STEAMSHIP "MAGNETA."

Since the loss of the "La Plata" the telegraph world has not had to deplore a catastrophe such as that which has now to be recorded, for it is useless to imagine that we can any longer have hopes of the safety of the missing steamer the "Magneta." During the week reports received from the captain of the "Palmyra" have stated that one of the boats belonging to the "Magneta" was seen 200 miles off Finisterre, and that there was no evidence of the boat having been occupied. The oars did not appear to have been used; a part of the mast was lying across the gunwale, and about 18 inches of top plank knocked in; otherwise the boat seemed to be in good condition, and appeared to have been properly lowered. There seems to be no doubt that the unfortunate vessel went down with all hands. The disaster may have arisen from one of several causes. It may have been directly due to the results of a storm. There is one point, however, generally overlooked in the loss of steamers. We do not wish to hint in the slightest possible manner that such an accident occurred in this case; but with every precaution taken machinery does sometimes go wrong, and no doubt many missing ships have been sent to the bottom through the bursting of their boilers. An accident of this kind, more especially if occurring in the midst of a storm, would almost necessarily be fatal. A full description of the ship appeared in our issue of 3rd January, from which it will be seen that the details of the construction had all been carefully considered, and, so far as can be seen, no effort had been spared to make the vessel thoroughly seaworthy and efficient in every respect. It is not, however, the loss of the vessel we so much deplore as the

Digitized by Google

loss of its crew, including as we do in this one general term the whole of the fifty-four souls on board. It will not be possible for us to refer to all of these, but we may mention the names of a few who seemed destined in the heyday of their youth to do good work in the service of the cable companies; their loss is felt, and their experience cannot be replaced.

THE LATE CAPTAIN MERRALL.

Captain Merrall was for some years in the service of the Telegraph Construction Company, and joined the Eastern Telegraph steamer "Chiltern" as second officer in 1880. In 1882—recommended by Sir James Anderson—he was appointed by the Eastern Extension Company first officer on board their repairing ship "Sherard Osborn." In September last Captain Merrall returned to England on leave of absence, and in January of the present year was instructed to proceed to Glasgow, and was appointed to the command of the "Magneta," then building on the Clyde. The vessel left the Clyde under his command on the 6th, and arrived in the Thames, after a somewhat stormy passage, on the 9th of February. The test of the ship during this passage was sufficient, in the opinion of the captain, to prove its suitability for the work before it. Captain Merrall had scarcely reached the prime of life, and during the five years he has been connected with the Eastern and Eastern Extension Companies gained the goodwill of all with whom he was brought in contact. By his untimely death the companies have lost a valuable officer and a skilled navigator.

THE LATE MR. J. M. MILLER.

Mr. James Miller, the chief electrician on board the "Magneta," joined the Eastern Extension Company in August, 1877, as telegraphist. In April, 1878, he was promoted to be assistant electrician, and in 1880 was given charge of the electrical department on board the company's hulk, "Southern Ocean." In July, 1883, he was appointed electrician on board the ss. "Agnes." In April of last year Mr. Miller left Singapore for England on leave of absence, and during his stay in this country he rendered great service to the company in suggesting and superintending the fitting up of the electrical department of the "Magneta." We had the pleasure of seeing him several times just before the commencement of his ill-fated voyage, and he spoke in glowing terms of doing good service with the vessel. Young and enthusiastic, and an exceptionally good electrician, the company and his friends have experienced a loss which will be long remembered.

THE LATE MR. T. E. WATSON.

Mr. T. E. Watson, chief engineer, joined the Eastern Extension Company in July, 1881, having only a few months previously had a narrow escape from drowning through the wreck of the "Braemar Castle," off Penang. He has held the appointment of chief engineer on board the ss. "Agnes" since the above date. Mr. Watson left the East last summer for England. In January of the present year he was appointed chief engineer on board the "Magneta." Mr. Watson was a very trustworthy officer, and as an engineer possessed great ability.

THE LATE MR. HENRY SEAWARD.

Mr. Seaward was returning to the East on board this unfortunate vessel, having been in the service of the Eastern Extension Company since 1870. For some few years Mr. Seaward was junior clerk at Madras, and in 1878 was appointed to a first class clerkship at Batavia; four years later he was transferred to Cape St. James as acting superintendent, which appointment was confirmed in 1883. Mr. Seaward was a very active man, and although firm he was kind to those under him, and made many friends who will be grieved to hear of his loss.

THE LATE MR. E. C. COX-SMITH.

Mr. Cox-Smith was a junior officer in the Company's Saigon Station, and joined the Eastern Extension Company's service in June, 1880. He came home on leave in August last, and was on his way back to his station. As an operator he possessed great ability, and was interested in the higher branches of electrical science. He was a great favourite among the staff in the East.

THE LATE MR. J. S. SHAPLEY.

This gentleman was for some years in the service of the Eastern Company, and joined the Eastern Extension Company in October, 1875, when he was appointed to the charge of the Nelson Station, where he has ably officiated in the capacity of superintendent since that date. Mr. Shapley was well known in the Australasian colonies, where he had made a large circle of friends.

Besides the gentlemen already mentioned, there were on board two young friends of Sir James Anderson, Messrs. Toynbee, who were going out to join their brother in an undertaking in the Straits. Mr. W. H. Webster, a personal friend of Mr. Lynes, the assistant-secretary of the Eastern Extension Company, was going to Malta, for the benefit of his health. This gentleman was well known and much respected at the Audit Office, Euston, where he has held an appointment since 1866. Messrs. Hughes and Jones, in the engineering department, were proceeding, the former to Perim for the Eastern Company, the latter to Tonquin to superintend the erection of the Company's quarters there.

INCANDESCENT LIGHTING IN AMERICA.

We quote the following from our American namesake:—"The following isolated plants have been recently introduced by the United States Electric Lighting Company, or are now in process of construction:—Washington Building, N.Y., 900 lights; New York Post Office, 1,200 lights; Frank Leslie's, N.Y., 200 lights; Union Ferry Co. (two new boats), 150 lights; Pennsylvania R.R. Station, Jersey City, 600 lights; Smith, Gray, and Co., Brooklyn, 160 lights; Palmer House Barber Shop, Chicago, 300 lights; Royal Insurance Co., Chicago, 1,155 lights; Home Insurance Co., Chicago, 1,500 lights; U.S. Custom House and Post Office at Chicago, 750 lights; ditto Cincinnati, 800 lights; ditto St. Louis, 750 lights; U.S. steel cruiser, 'Atalanta,' 200 lights; Las Vegas Hot Springs Co., Hotel, New Mexico, 652 lights; Geo. H. Friend and Son, W. Carrollton, Ohio, 60 lights; College of Ottawa, Ottawa, Ont., 100 lights; New York and Phila. and N.R.R. Co., steamer 'Cape Charles,' 75 lights; Middlings Purifier Co., Jackson, Miss., 250 lights; Nashville Cotton Co., Nashville, Tenn., 250 lights; P. Espinal, Theatre, Caracas, Venezuela, 500 lights; Battle House, Mobile, Ala., 200 lights; Fred. Hauson, Hotel au Claire, Wisconsin, 100 lights; Samuel Cupples's Factory, St. Louis, Mo., 150 lamps; Huron Mills, Ypsilanti, Mich., 150 lights; U. S. Post Office, Philadelphia, Penn., 600 lights; E. W. Hydorn and Son, Troy, N. Y., 690 lights; A. S. Turner, Elmira, N. Y., 575 lights; Mortimer Building, New York, 100 lights; Hamilton Club, Brooklyn, 300 lights; Mutual Life Assurance Co., new building, New York, 750 lights. This last plant has been substituted for a large installation of Sawyer and Mann lamps, which has been in operation for lighting the building for some time past, but has been rejected as unsatisfactory, and the Weston incandescent system substituted for it. A new stock company is to be formed in Chicago for the manufacture of a new system for operating incandescent electric lights, invented by Harold P. Brown, electrical engineer. Electric light companies have been formed in Columbia and Lancaster, Penn."

A NOVEL APPLICATION OF ELECTRICITY.—In the *Elektrotechnischer Anzeiger*, of Berlin, there is a description of a somewhat novel installation in one of the cafés in that city. Electricity not only lights and ventilates the building, but *prepares the coffee*. In the centre of the establishment is placed a buffet carrying a small electric motor which works a coffee mill. The water is heated in a large glass bottle in which is placed a spiral of platinum wire traversed by the current; a quarter of an hour suffices to heat the water to boiling point. There are no waiters to serve the customers; each table is in communication with the central buffet, and by means of a small electric railway, the articles required for consumption are transported to the visitors.

CONDENSERS.

We invite those of our readers who are Electricians and who have Condensers in their charge to kindly furnish us with information as to the actual capacity of such Condensers as against the nominal value; together with a note of the temperature readings with both wet and dry bulbs; and any other data which may be of interest.

WAR AND SUBMARINE CABLES.

In our last issue we drew attention to the unsatisfactory condition of our lines of telegraphic communication with the East; and we are glad to observe that the matter has been promptly brought to the notice of the Government through Parliament. Not that we can suppose that this is the first time they have given any consideration to the subject; on the contrary, their advertisement for tenders relating to certain West African cables some months ago shows that Ministers were beginning to realise the true situation of affairs. But there still appears to be great lack of knowledge as well as great diversity of opinion among heads of Departments as to what steps should be taken to remedy the defects of the existing system, and even as to the utility of any steps whatever that could be taken.

This was singularly manifest in the short discussion which arose on Viscount Sidmouth's question in the House of Lords on Tuesday evening. Our note of warning last week had direct reference to the possibilities of a war with Russia, and the difficulty of maintaining telegraphic communication with India, independently of foreign Administrations, should hostilities unfortunately break out. For reasons quite intelligible at the present juncture Viscount Sidmouth confined his inquiry to the case of China, asking whether any attention had been given to the fact that our sole route of telegraphic communication with Hong Kong and other British settlements—including, no doubt, certain important coaling stations—in the East was by wires passing through territory belonging to foreign Powers. Lord Derby in his reply ignored the facts alluded to in our note as touching the routes taken by the wires nearer home; but was constrained to admit that at their distant ends they had to pass either through Russian and Chinese territory, or through the French settlement at Saigon. With the usual official optimism his lordship deemed it of great advantage that these two routes were available, because if we were at war with one Power there would still remain the route belonging to the other. The contingency of a war with both Powers at the same time, or with one Power who had a very good neutral friend in the other, does not seem to have occurred to the Colonial Secretary. We sincerely hope he may not be rudely undeceived. Of course the question of cost came in. The maintenance of an independent line from Singapore to Hong Kong would involve an expenditure of £20,000 a year. We think there is some mistake here; but as another noble lord, the head of the Naval Department, virtually admitted that considerations of cost ought not to outweigh political considerations, nothing more need be said on that point.

But Lord Derby added as a final reason for doing nothing a fact alluded to in our last week's note—namely, that to secure complete independence of communication we must have fresh lines to Gibraltar and Malta. Now, as to this, although a point of some importance, it is not to be compared with the facts of our dependency largely upon wires passing through Russian and French territory. The present submarine lines to Gibraltar and Malta touch at Vigo and Lisbon; places which, we need hardly say, are on territory far less likely to be involved in hostilities than the countries we have named. Besides, as we pointed out at the time, these cables could, in case of need, be detached, so to speak, and spliced through to their British destination. We were right in saying that our position in respect to direct communication was not generally understood. An ex-Colonial Secretary, joining in the discussion, questioned the accuracy of Lord Derby's concluding statement that we had no direct cable communication with Gibraltar, alleging that he—Earl Carnarvon—had actually seen it at work. What he had seen, no doubt, was the direct transmission of messages between London and Gibraltar or Malta, from which he has apparently inferred that the cable went straight to its terminus. It might surprise him to be told—which is quite possibly the fact—that what he saw was the transmission of messages across France by way of Marseilles; and France is at all events a possible foe in the event of a European war.

But, by whatever way Earl Carnarvon's "direct" communications travelled, it is certain that under existing arrangements a large portion of the telegraphic traffic to the East goes by way of France; and there consequently arises the very important question of Lord Salisbury, as to whether a neutral nation can maintain its neutrality and yet transmit war messages for one of the belligerents. That such a question has been raised—as we understand Lord Salisbury to say it has—and still remains to be settled, is a startling announcement. On the face of it the same principle ought to apply to Telegraphs as to Mails; but, as was pointed out, if the neutrality of the country over which war telegrams travelled were not of a very benevolent kind—in other words, was rather hostile than friendly—the importance of independent submarine cable communication becomes very great indeed.

Digitized by Google

Earl Carnarvon's suggestion that requisite stores and appliances should be accumulated at suitable places ready to repair, to supplement, or to divert the routes of cables injured by the enemy, or touching unfriendly soil, is deserving of immediate attention. Hitherto the Government have relied almost solely upon the commercial instincts of the nation to supply communication and keep it unimpaired. They have also received much help from the patriotism of owners of cables, who have gone outside their commercial province in order to give the Government a helping hand. But it is time the Government helped themselves. They might have had more than one absolutely independent cable route to the East if they had chosen to recognise frankly the fact that the telegraph is an imperial as well as a commercial necessity. They have allowed the lines to take a purely commercial track, without providing for their instant conversion into political routes; and they have offered no pecuniary inducements—with only one exception recently, we believe—for the construction or extension of lines where commerce alone would not attract them. As to initiating a line on political or military considerations exclusively, it seems never to be thought of; at all events, England will be agreeably surprised if, when the next war breaks out, it is found that ample provision—or, indeed, any provision at all—has been made to enable this country to assume exclusive control over her communications with those distant dependencies which she is bound to protect, and on whose safety the success of her own naval and military operations so much depends. There are two or three obvious measures required to render us more secure in these and similar respects—measures which we hope may be adopted at once, but which on the eve of a great war we need not specify more precisely.

CORRESPONDENCE.

DOMESTIC ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of April 11th appears a letter advocating the use of Balmain's luminous paint in the construction of commutators for household fittings. The writer of that letter is in error in supposing that such an application of the paint has not occurred to constructors. We should imagine that many will have used it. We put rings of luminous paint round the commutators in our very first incandescent installation, and we have used it freely for commutators, electric-bell pushes, and indicators, &c.

Electric light commutators should always where possible be put near the door, as the light of the paint does not prevent people stumbling over things on their way across a room. So fitted they answer their purpose admirably.—Yours, &c.,

ANDERSON AND MUNRO.

136, Bothwell-street, Glasgow, 11th April, 1885.

NEW ORLEANS EXHIBITION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with much interest Mr. Verity's description of the Edison exhibit at New Orleans in your last issue.

I also have recently returned from the United States, where I was on electric lighting business, and I must say that one thing struck me quite differently from Mr. Verity—viz., the extension of the incandescent system to the detriment of the arc. I quite agree with him that such installations as the New York Down Town Station are unknown here, and the use of the incandescent lamp is no doubt increasing enormously; but I hardly think it is replacing the arc. I am interested in electric lighting generally, and, as my connection with the Edison-Swan system proves, extremely so in the incandescent system, though the arc, also, most certainly has its place. For interior or domestic illumination the glow lamp reigns supreme, and the arc is inadmissible; but for large open spaces, high workshops, stations, streets, squares, docks, &c., the arc must prevail; and this is fully appreciated in America, as may be shown when I mention that the arc system (the Thomson-Houston), which my firm are now introducing into this country, has put up since its commencement, little more than a year ago, over 9,000 lamps, and the daily out-turn at the factory is a hundred light plant complete.

The appearance of the streets of the American cities certainly would, without other proof, show that the arc system was not yet doomed, for they are a regular blaze of light. At one corner in New York I counted 78 arcs that I could see without moving. By walking a few steps to get different views down the four streets at the corner I could see 20 to 30 more. This appears almost incredible to English ideas; but I hope we may see the day [night? ED.], and that very soon, when our streets may be properly lighted by arcs, the value of this light being fully appreciated by our cousins, whose dictum is that "every arc replaces a policeman."—Yours, &c.,

C. J. WHARTON.

8 and 9, Holborn-viaduct, April 13th, 1885.

INCANDESCENT LAMPS AND THEIR HOLDERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of March 14th appeared a letter from Mr. Sydney Walker, headed as above, and illustrating, as new, a form of holder that has been very familiar to me for the past two years. Having no reference handy, I cannot give exact dates, but possibly Messrs. Woodhouse and Rawson can supply the omission, as whilst in their service I designed a holder similar in every respect, and which I have always understood was patented at the same time as their other three-pronged form.

Of course, in mentioning the matter I do not wish to convey any imputation against Mr. Walker—far from it; but possibly early notice of the matter may prevent future unpleasantness, and as Mr. Walker admits that until *very recently* they could find no better form than the old Swan spiral, doubtless my priority will be readily acknowledged, though both parties may be *bonâ fide* inventors of the same article.

In conclusion, allow me to endorse Mr. Walker's good opinion of the holder.—Yours, &c., C. SCOTT SNELL.

Culver Park, Saltash.

ANIMAL ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The smart, racy letter of "A. S. T. E." in your issue of 21st February fits in most admirably with the letters from W. A. Rudge, which appear also on the same day and in a previous issue of your very useful paper.

I have no doubt that every electrician has observed in a greater or lesser degree all the phenomena your correspondents describe, but a very natural feeling of uncertainty, when we are all groping so very much in the dark, causes one to hesitate before committing to publicity, as absolute facts, the thousand and one apparently remarkable things that the practical electrician is daily stumbling across whilst pursuing even the ordinary routine of his profession, and it is to be regretted that the time requisite for following them up is invariably denied him.

I quite anticipated, however, seeing a very voluminous correspondence to you on the subject, considering its really great importance, and I am at a loss to understand how it is that so very few amongst the readers of so valuable a paper as *The Electrician* has now become take little more than a passing interest in any other than those facts appertaining to the old and universally-accepted beaten track of electrical science, when it is considered that, advanced as it is, we are practically as ignorant of the true origin and nature of what electricity is as were the earliest pioneers in their primitive explorations of it; and therefore we should leave no stone unturned in following out to the end any ideas which may tend to enlighten our comparative ignorance.

Digitized by Google

The question of animal electricity is a very profound one, and anybody who has studied it and experimented upon it must confess that at least the sense of touch and the workings of the mind by thought itself are, of all others, subject and subservient alone to the static electricity which everything in life is endowed with.

If, as a *manière de parler*, we look upon the earth as a general reservoir into which all positive electricity is pumped, so must we consider animal life as the generating. or negative plate, which goes on yielding the same, whether collected from its own source or whether induced from "mother earth," until animation ceases and the "vital spark" has fled for ever.

It is most interesting to watch experiments relating to this force, and I agree to a very great extent with "A. S. T. E." that the rapidity in the circulation of the blood causes an apparent increase in the volume of electricity produced. I look upon it precisely in the light of a "recorder mouse mill" (and to no better electrical machine can animated things be compared), which, if driven very rapidly, will give out, for a time, more power, brightness, cheerfulness, and vitality. But the pace will tell, its speed drops all of a sudden, it stops, it is exhausted, dead; but if driven steadily, and not abused, both the mill and the animal last out that period of time allotted to all things in nature.

My experiments in animal electricity began several years ago, and were frequently made on both bipeds and quadrupeds, giving nearly equal results. The same difference between perfectly healthy individuals and animals that "A.S.T.E." found amongst his sound, debilitated, or phlegmatic subjects, I also found; but what I did notice then, as ever since, was that although my subjects might be perfect, both mentally and physically, the externally nervous, timid man, woman, child, or dog, gave comparatively far lower deflections on my astatic galvanometer than the stolid and immovable-at-any-price natures whose pulses would not beat a trifle higher were a 100-ton gun fired beside them. And I remember commenting on this in 1883, when the fleet under Lord John Hay was here, and when many of the officers were one day visiting my laboratory, each in turn being experimented upon. The difference in the results obtained was remarkable, and as they were all in the best of health I concluded that the difference was entirely due to their nervous condition, and which I verified on questioning them; and I feel confident that that which we call nerve is but the "collecting plate" of the force known as animal electricity, and in proportion to the nerve's strength so is that power retained, to be yielded only when the owner of it *so wills it*, whilst in the nervous man it is as in the defective "mouse-mill," where the electricity cannot be retained, but is ever oozing out, and its power necessarily vitiated. And this is marvellously exemplified in observing the assimilated conduct of a faulty mouse-mill in damp, muggy weather with a man of highly external nervousness. The energy of both is equally absorbed by the damp air, and the result is a profound melancholy in the one and a more melancholy failure in the other.

I was surprised to see that the deflections from "A. S. T. E.'s" subjects were so low. In some cases I have obtained 300 divisions of the scale with a 100 shunt, and that this only gives a faint idea of the actual volume of electricity produced I will endeavour to show, the more so as it is very interesting, and gives one a better idea of what the actual internal resistance of the human cell is. It is well known that in measuring low resistances with a very high resistance galvanometer the multiplying power of the shunts marked $\frac{1}{9}$, $\frac{1}{99}$, and $\frac{1}{999}$ is not that indicated thereby; in fact, it is entirely disproportionate, and the insertion of one or the other of these shunts but very slightly alters the actual deflection of the unshunted galvanometer. But in measuring the animal electricity produced by a human cell I have carefully noted that the multiplying power of the 10, 100, or 1,000 shunts used is nearly if not quite equal in proportion to the deflection of the unshunted galvanometer. Hence it is reasonable to suppose that the internal resistance of the human cell is to be measured, if not in megohms, at least by many thousand ohms—or in other words the intensity of the electricity it could produce, were its internal resistance very low, would be indeed dangerously great.

When these facts are duly taken into consideration, we must confess that the application of electricity for medicinal purposes could be made almost universal, provided that proper attention is paid to the above laws, which alone regulate such applications, and by confining them to Faradic currents only.

Many years ago, I remember applying Faradic currents to cure myself of chronic toothache, to which I had been a martyr for months. I nearly wrenched off my jaw, but I cured it effectually, by killing the nerve, and, although the decay goes on, I have never known toothache from that day to this. Some ten years ago I fell in with a very clever young doctor, who was just developing his electro-therapia in the large hospital of Sta Maria Nuova, in Florence, and although his applications of voltaic currents gave a certain amount of satisfaction, he, at my suggestion, almost entirely discarded them for the Faradic, and really made some remarkable cures. Still, with all this, electro-therapia makes little or no progress.

I have spun this letter out too long to answer friend Rudge, but let him be assured that all his interesting results are very well known, though, alas, he is about the only one who has ever brought them into public notice.

In a further letter I will let him know something more on this interesting and valuable subject.—Yours, &c.,

Zante, April 6, 1885. W. G. FORSTER.

BITUMINOUS COMPOSITION FOR STREET MAINS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Can you or any of your readers inform me what is the exact nature of the bituminous composition employed as an insulating medium in the Edison electric street mains, and also say at what temperature it melts?—Yours, &c.,

S.

April 2nd, 1885.

THE VAN RYSSELBERGHE SYSTEM OF SIMULTANEOUS TELEGRAPHY AND TELEPHONY.

BY M. CHAS. MOURLON.

(CONTINUED FROM PAGE 460.)

II.

As a result of this discovery, M. Van Rysselberghe recommends for the production of the current an element or elements of extremely low internal resistance. In that case

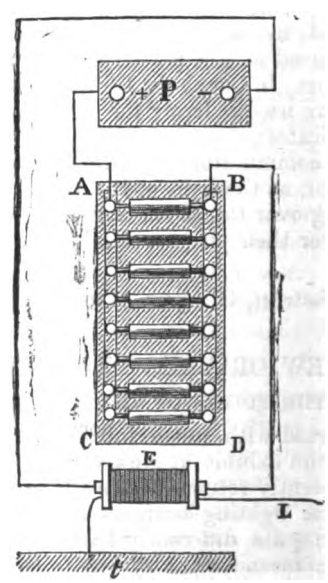

FIG. 3.

secondary cells or accumulators and thermo-electric piles can be employed with advantage. It is not, however, sufficient to diminish the internal resistance of the battery; the resistance of the microphone must also undergo diminution, and in order to effect that purpose he has had recourse to a number of con-

Digitized by Google

tacts arranged in multiple arc. This arrangement is shown in Fig. 3.

P, may be either a Planté or a Faure accumulator, or a Leclanché or Warnon cell of large plate surface, and therefore of low internal resistance. A B C D, is a small deal planchette or table, of the same dimensions as that adopted for the Ader microphone. Upon this are disposed, parallel to each other, eight small carbon pencils, connected in multiple arc, and constituting the contacts of the microphone. The total resistance of this instrument does not exceed 2 ohms, whilst that of the greater number of the microphones in ordinary use is about 16 ohms. E, is an induction coil having a primary circuit of small resistance. M. Van Rysselberghe has also minimised the resistance of the secondary circuit, for the reason that long-distance transmission necessitates the use of currents of *quantity*, and not of *tension*. In Fig. 4 the ordinary apparatus designed for service in a telephone office, for long-

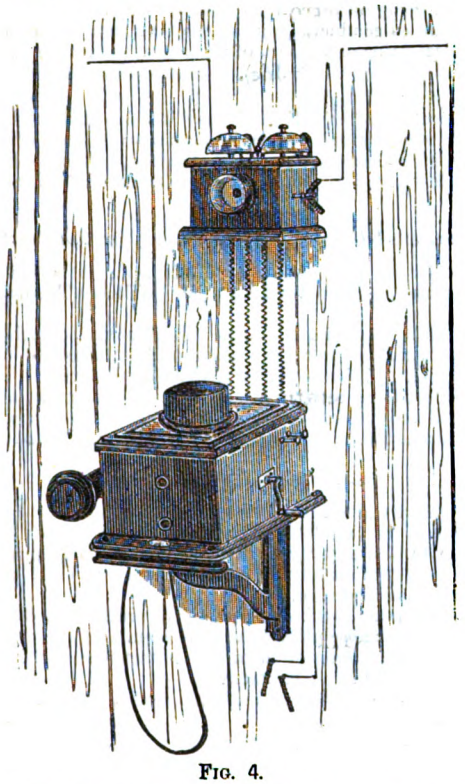

FIG. 4.

distance working, is shown. This apparatus consists of a box of walnut wood containing a complete inductor, which, by means of a small crank placed at the side of the box, actuates the two bells in connection with the two offices. These bells are entirely independent of the transmitting apparatus.

The cover of the before-mentioned box also carries the carbons of the microphone. The small table which supports them is, as we have said, somewhat similar to that of the Ader microphone, but it differs from the latter in that instead of being fixed it is merely packed in a metallic frame. The receiver is a Bell telephone, sheathed in ebonite, the resistance of the coil of which is less than 100 ohms. This receiver rests upon two hooks, one of which is fixed, while the other, which is automatic, acts as a commutator. The installation of the apparatus is very easily effected, and, once placed in position, it does not require to be regulated, nor is it liable to get out of order. An ebonite cylinder is arranged upon the table of the microphone in order to collect the sound vibrations, and direct them perpendicularly upon the diaphragm. This modification is a very simple one, and has given excellent results in regard to distinct articulation.

Fig. 5 is a second model, in which the micro-telephone is mounted upon a desk, so that the messages may be written down as they are received. A paper clip in the form of a hand serves to retain the paper in position. The magneto call is placed beneath the desk, and is put in action by a small crank wheel, which, together with the bell, is of the same description as in Fig. 4. There are six terminals in all, L, communicating with the line, T with the earth, SS, with the two bells, while P P, are connected to the respective poles of a Leclanché battery of the large pattern, placed in a box underneath the apparatus, and resting on the ground.

The last experiments of M. Van Rysselberghe, conducted in the presence of the officials of the Belgian State, sufficiently proved that in order to arrive at perfection it was necessary to make use of very sensitive microphones. The objection has been urged that the expense of replacing the instruments ordinarily used by those of the new system would be considerable, and in order to meet this objection, M. Van Rysselberghe has specially designed some effective and economical improvements to the existing apparatus. The later experiments which have been conducted, *i.e.*, between Ostend and Brussels, 77·5 miles; Antwerp and Brussels, 34·1 miles; Paris and Brussels, 207·7 miles; Oporto and Lisbon, 193·6 miles; Rouen and Le Havre, 57 miles; and, finally, in the Argentine Republic, between Buenos Ayres and Rosario, a distance of 217 miles, have given every satisfaction. The microphones used in these experiments were the same which have been installed in the Theatre de la Monnaie in Brussels, and which enabled Her Majestry the Queen of the Belgians to hear at her Châlet Royal at Ostend, and later at the Laeken Palace, the

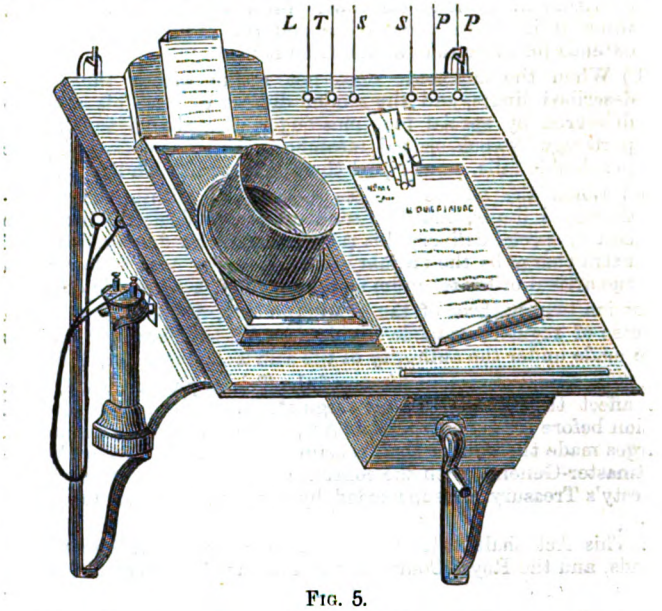

FIG. 5.

music and songs of the opera in Brussels. On the latter occasion the Bell Telephone Company in that city lent its wires from the theatre to one of the offices of the State, which was in actual telegraphic communication with the Palace of Laeken, situated some miles from the town; and, although the music was transmitted distinctly and satisfactorily, no interruption whatever resulted to the telegraphic service then being carried on. As a result of that experiment Her Majesty has ordered a permanent installation to be put down between the Palace and the Opera House in Brussels. The number of microphones necessary for such an installation is fourteen. These are all mounted in multiple arc, and connected to a Faure accumulator of 50 kilos. placed beneath the stage. The accumulator is fed continually by a Bunsen battery, which also serves to actuate the regulators required during the representations in the electric lighting of the stage.

THE NEW TELEGRAPH BILL.

The following is the text of the new Sixpenny Telegraph Bill :—

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows :—

1. This Act shall be read as one with the Telegraph Acts, 1863 to 1878, and shall be deemed to be a Post Office Act within the meaning of the Post Office (Offences) Act, 1837 ; and this Act may be cited together with the Telegraph Acts, 1863 to 1878, as the

Digitized by Google

Telegraph Acts, 1863 to 1885, and may be cited separately as the Telegraph Act, 1885.

2. Section fifteen of the Telegraph Act, 1868, shall be repealed, and in place thereof be it enacted as follows :—

The Postmaster-General, with the consent of the Commissioners of Her Majesty's Treasury, may from time to time make regulations for determining the hours during which the offices appointed by him to be places for the receipt and despatch of telegrams shall be open for the transaction of telegraphic business, and for fixing the sums to be from time to time paid on account of the transmission of telegrams, and on account of services rendered in connexion therewith, and on account of the use of the telegraphs by any persons, and for determining the conditions and purposes on which and for which such use may be permitted, and for the general conduct of telegraphic business : Provided that

(1.) The charges for the transmission of written telegrams throughout the United Kingdom shall uniformly and without regard to distance be at a rate not exceeding *sixpence* for the first twelve words of each telegram or for each telegram of less than twelve words (counting as part of such twelve words the names and addresses of the sender and addressee of the telegram), and not exceeding *one penny* for each additional two words or part of two words :

(2.) The sums charged for the transmission of written telegrams shall be held to cover the costs of delivery by special foot messenger, within the limit of one mile of the terminal telegraphic office, or within the limit of the town postal delivery of that office, when it is a head post office and the town postal delivery extends for more than a mile from it :

(3.) When the addressee does not reside within the above-described limits, and the sender desires to have his telegram delivered by special foot messenger, the charge to him for porterage by such special messenger shall not exceed *sixpence* per double mile, or any part thereof, beyond such limits :

(4.) When the addressee does not reside within the above-described limits, and the sender does not desire to incur the cost of special delivery, his telegram shall be delivered free of extra charge by the ordinary postal delivery next following on the arrival of his telegram at the terminal telegraphic office.

Section twenty-three of the Telegraph Act, 1868, shall apply in the case of regulations made under this Act as if such regulations were made under the authority of the said Telegraph Act, 1868.

3. The repeal of section fifteen of the Telegraph Act, 1868, shall not affect the validity of any regulations made under the said section before the passing of this Act, and such regulations and all charges made thereunder shall remain in force until revoked by the Postmaster-General, with the consent of the Commissioners of Her Majesty's Treasury, or superseded by regulations made under this Act.

4. This Act shall extend to the Isle of Man and the Channel Islands, and the Royal Courts of the Channel Islands shall register the same accordingly ; and for all the purposes of this Act the Isle of Man and the Channel Islands shall respectively be deemed to be part of the United Kingdom.

ON THE SEAT OF THE ELECTROMOTIVE FORCES IN THE VOLTAIC CELL.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

(CONTINUED FROM PAGE 463.)

12. This is perhaps the most convenient place to introduce the notes or condensed statements which I drew up and distributed at the meeting before the discussion. They were intended to be critically exact (allowing of course for mistakes and possible slips) so as to bear analysis ; and hence it is probably worth while to reproduce them here with notes and comments.

I. *Orthodox Statements believed by the writer to be true in the form here set down.*

A. *Volta.*

i. Two metals in contact ordinarily acquire opposite charges† ; for instance, clean zinc receives a positive charge by contact with copper, of such a magnitude as would be otherwise produced under the same circumstances by an E.M.F. of about ·8 volt.

ii. This apparent contact E.M.F. or "Volta force" is independent of all other *metallic* contacts wheresoever arranged ; hence the metals can be arranged in a numerical series such that the "contact-force" of any two is equal to the difference of the numbers attached to them, whether the contact be direct or through intermediate metals. But whether this series changes when the atmosphere, or medium surrounding the metal, changes, is an open question ; on the one side are experiments of De la Rive, Brown, Schulze-Berge ; on the other side of Pfaff, Pellat, Thomson, Von Zahn.* It certainly changes when the free metallic surfaces are in the slightest degree oxidized or otherwise dirty. And in general this "Volta force" is very dependent on all non-metallic contacts.

iii. In a closed chain of any substances whatever, the resultant E.M.F. is the algebraic sum of the Volta forces measured electrostatically in air for every junction in the chain, neglecting magnetic or impressed E.M.F. [Verified most completely by Ayrton and Perry.]

B. *Thomson.*

iv. The E.M.F. in any closed circuit is equal to the energy conferred on unit electricity as it flows round it.

[Neglect magnetic or impressed E.M.F. in what follows.]

v. At the junction of two metals any energy conferred on, or withdrawn from, the current must be in the form of heat. At the junction of any substance with an electrolyte energy may be conveyed to or from the current at the expense of chemical action as well as of heat.

vi. In a circuit of uniform temperature, if metallic, the sum of the E.M.F.'s is zero by the second law of thermo-dynamics ; if partly electrolytic, the sum of the E.M.F.'s is equal to the sum of the energies of chemical action going on per unit current per second.

vii. In any closed conducting circuit the total intrinsic E.M.F. is equal to the dynamical value of the sum of the chemical actions going on per unit of electricity conveyed ($\Sigma \cdot J\theta\epsilon$), diminished by the energy expended in algebraically generating reversible heat.

viii. The locality of any E.M.F. may be detected, and its amount measured, by observing the reversible heat or other form of energy there produced or absorbed per unit current per second. [This is held by Maxwell but possibly not by Thomson† though its establishment is due to him.]

II. *Statements believed by the writer to be false though orthodox.*

ix. Two metals in air or water or dilute acid, but not in contact, are practically at the same potential.‡ [Sir William Thomson, Clifton, Pellat.]

x. Two metals in contact are at seriously different potentials (*i.e.*, differences of potential greater than such millivolts as are concerned in thermoelectricity). [This is held by nearly everybody.§]

xi. The contact force between a metal and a dielectric, or between a metal and an electrolyte such as water and dilute acid, is small.‖ [Ayrton and Perry, Clifton, Pellat, and probably Sir William Thomson.]

CHAPTER III.—*Theoretical.*

13. Statement of the writer's own views.
14. Example of the calculation of a Volta-effect.
15. Attempt to mentally represent the action of atmosphere on metals at the instant of contact. Mode in which two Volta plates may be regarded as a condenser.
16. Qualifications and doubts respecting the precise calculation of Volta-effects even for absolutely clean pure metals.
17. Calculation of a series of metal-air contact-forces ; *i.e.*, of an absolute Volta series in air or water.
18. Calculation of Volta series in other media, such as chlorine and sulphur.

Additional note.

13. Before proceeding to the statements embodying my own views, it

* Reprinted from the *Phil. Mag.* for April.

† Observe that it is not said that two metals in contact acquire different potentials. Such difference of potential I believe to be only apparent. Compare Figs. 14 and 15.

* I put Von Zahn on that side because he himself considers himself there, and because the great bulk of his experiments lean decidedly that way.

† The only reason which I can think of as likely to have caused Sir William to doubt or deny the validity of this proposition is given and, I hope, refuted at sections 10 and 11.

‡ The truth or falsity of this statement may be held to depend on a question of words, viz., the definition of potential. Sir William at the meeting said he had always defined potential as the work done in bringing a unit charge close up to, but not *into*, the body. This definition explains some apparent inconsistency in one or two of his utterances which I had never quite understood. But seeing that there is no difficulty whatever in giving a charge up to a metal body, but rather the contrary, why not define its potential in the more simple manner which followers of his have unconsciously, and I believe universally, adopted, not knowing that they were thus putting themselves out of harmony with him ? Given his definition, so that the potential of a body means really not its potential but the potential of the medium close to it, statements Nos. ix. and x. are undoubtedly true ; and No. xi. is also true, I suppose, for it then only means that there is not much E.M.F. between the medium close to a metal and that at a little distance.

§ It is much more natural to suppose that the potential of a metallic conductor is uniform, whether it is homogeneous or not. Indeed, it is not only more natural, but it is true, that two parts of a conductor *can* only differ in potential by reason of an E.M.F. located at the junction. Now there usually is an E.M.F. at a junction, but it is only of such a magnitude as is concerned in thermoelectricity. This, indeed, does produce a difference of potential between the metals, but nothing else can. N.B.—Always provided that by "the potential of a metal" is meant that potential, and not the potential of air near it.

‖ The experiments supposed to establish this really prove only that there is very little difference between the air and the water in which a metal is partially immersed. I do not quite know how to understand, on Sir William's plan, the potential of a metal which is half in one medium and half in another.

Digitized by Google

will be more interesting if I try to explain in a fuller and more connected manner what they are.*

Let us regard the air as a dielectric bath of oxygen, in which metals are immersed, and picture a piece of zinc surrounded by oxygen molecules which are straining at it, and endeavouring to combine with it. They may indeed partially succeed ; but suppose they do not, we have here a strong potential chemical action or chemical strain which must probably be accompanied by some physical phenomenon. Now, remember that oxygen is an electro-negative element, and without endeavouring to examine too precisely what signification is involved in that statement, it will be not out of accord with orthodox views if we assume that it means that at least any dissociated oxygen atoms are negatively charged, each with the characteristic charge of a free dyad atom. Granting something equivalent to this, without pressing the form of expression too closely, we perceive that the strain of the oxygen towards the zinc will result in what I metaphorically call a slackening up, or attempted compression, of the negative electricity in it, *i.e.*, in a rise of negative potential. We may therefore say that zinc is at a lower potential than the air surrounding it, and that the step of potential in crossing the boundary from zinc to air is closely connected with the chemical affinity between zinc and oxygen. Observe that this step of potential does not obviously nor probably depend on the amount of oxygen present. It is possible that a few million molecules may be as effective as a large number. Note also that the step of potential is by no means caused by actual oxidation ; in so far as the zinc surface is tarnished by oxidation the strain will be diminished and the step of potential become less.

Nothing is said here about the possible effect of the nitrogen, because it is simplest in the first instance to ignore it, though whether experiment will justify this simplicity or not, I do not yet know.

We may go further and assert that if in general the chemical affinity of two substances can be measured by their energies of combination, then the step of potential in the present case may perhaps be calculable from the heat of combustion of zinc.

And one may justify this assertion thus. Let an atom of oxygen combine with an atom of zinc ; it will generate an amount of heat h, and its characteristic charge, q, will be given up to the zinc and will thereby fall down the step of potential, v, which separates the zinc from the air. *Now, if we suppose that the heat* h *is the representative and equivalent of the fall of energy* q v, it follows, of course, that

$$v = \frac{J\,h}{q}.$$

Make the hypothesis and see what comes of it.

14. The oxidation energy of zinc per gramme-equivalent (*i.e.*, 65 grammes of zinc or 16 of oxygen) is, according to the determinations of Julius Thomsen, Andrews, and Favre and Silbermann, 85,430, 84,825, and 83,915 respectively.

The amount of electricity needed to deposit a gramme-equivalent of zinc, or of any dyad element, is, according to the modern determination of Lord Rayleigh†, 19,320 units.

Hence the value of $\frac{h}{q}$, which is a ratio evidently independent of the number of atoms dealt with, lies between $\frac{85400}{19320}$ and $\frac{84000}{19320}$ probably. Let us say it is $\frac{85000}{19320}$ or 4·4.

Now J in absolute measure is 42×10^6 ; so the value of v, which is $\left(\frac{J\,h}{q}\right)$ according to the above hypothesis, comes out $1{\cdot}85+10^8$, that is 1·85 volt.

This then, I say, is the step of potential between zinc and air. (To avoid circumlocution I will henceforward speak as if the above hypothesis were admittedly true, and all I now say stands or falls with it.)

All clean bright zinc is thus about 1·8 volt below the potential of the air near it ; tarnished or oxidised zinc will exhibit less difference ; and it is perhaps possible that perfectly oxidised zinc need show no difference of potential at all between itself and the air. The step of potential by no means therefore depends upon the occurrence of oxidation ; it is the oxidation *tendency* which causes it, but so far as oxidation actually takes place the step diminishes.

Proceed to consider a piece of copper similarly. Oxygen molecules are straining at it also, but with less force. The combustion energy of copper per gramme-equivalent is given by the three authorities already quoted as 37,160, 38,290, and 43,770 respectively. These do not agree well, and it is difficult to know which to take ; but Thomsen's results are, I believe, generally relied on ; so, assuming his, the step of potential between copper and air will be $\frac{\cdot42\times37200}{19320}$ volts, that is about ·8 volt. This then is the amount by which clean bright copper differs from the air. Oxidised copper will differ less. Comparing this value for copper with that just obtained for zinc, we perceive that a piece of zinc and a piece of copper are, when separate, not at the same potential ; they differ by about a volt from each other. If the zinc is oxidised, they differ less : if the copper is oxidised, they differ more.

Now put the zinc and copper into direct metallic contact, and neglect for the present the third of a millivolt of E.M.F. developed at the junction, which acts so as to drive positive electricity from copper to zinc. A rush of electricity must take place from the copper to the zinc to equalise their potential ; it is impossible that they can remain at different potentials when directly united : all parts of a conductor must be at a uniform potential, and the rush has taken place because they were not so when put into contact.

15. Picturing to ourselves the effect as produced by the straining oxygen atoms, we shall perceive that they could not get at either metal when separate : first, because they surrounded it everywhere, and strained equally on all sides ; and second, because, being all charged with negative electricity, they could not move in on all sides at once without, so to speak, compressing the electricity in the body and giving it an absolute charge. But directly the copper touched the zinc the oxygen atoms were cleared away at the point of contact, and the stress of those at the rest of its surface was no longer counterbalanced. Moreover, they *can* now all move nearer to the zinc because a way of escape for electricity is provided into the copper, whose surrounding oxygen atoms will be thus driven back somewhat further from the surface, until the dielectric strain, assisting the chemical strain on the copper surface and opposing it on the zinc surface, prevents further displacement, and equilibrium is again attained. The electricity which escaped from the zinc to the copper was negative electricity (oxygen being essentially an electro-negative element), the negatively charged oxygen atoms have moved a little nearer to the zinc than their normal distance : *i.e.*, the thickness of its layer of negative electricity is reduced, or its surface is positively charged ; the negative layer on the copper has been slightly thickened—its surface is negatively charged.

This is a pictorial way of representing the process, and may be regarded as somewhat fanciful ; it is, however, the way in which the theory originally occurred to me, and it permits more insight into the processes than a mere statement in terms of potential can ; though it may well be that the imagined processes are but distant likenesses of the real ones.

The oxygen atoms have moved nearer to the zinc ; it is now more easily oxidized than before. The copper, on the other hand, is by contact with zinc somewhat protected.

(TO BE CONTINUED.)

* The reason I set them forth at length is because I had no time at the meeting both to open the discussion and also to properly express my own ideas, and Sir William Thomson was kind enough to tell me to write out the paper completely, and to explain the position I took up fully. This, therefore, I have endeavoured to do.

† "4·025 grammes of silver are deposited by an ampere current in an hour" (Montreal Address). This gives the electrochemical equivalent of silver ·01118, and of hydrogen ·00010352.

EXPERIMENTAL RESEARCHES IN MAGNETISM.*

BY PROFESSOR J. A. EWING, B.SC., F.R.S.E., UNIVERSITY COLLEGE, DUNDEE.

The paper describes in detail experiments of which preliminary notices have already been published. The experiments relate to—

(1) The magnetic susceptibility of iron and steel, the form of the magnetisation curve, and the changes of magnetism caused by cyclic changes of magnetising force.

(2) The influence of vibration on magnetic susceptibility and retentiveness.

(3) The influence of permanent strain on magnetic susceptibility and retentiveness.

(4) The energy expended in producing cyclic changes of magnetisation.

(5) The ratio of residual to total induced magnetism.

(6) The changes of induced and residual magnetism caused by changes of stress.

(7) The effects of constant stress on magnetic susceptibility and retentiveness.

(8) The changes of magnetism caused by changes of temperature.

(9) The effect of temperature on magnetic susceptibility.

The experiments were conducted on pieces of metal which gave as near an approach to the condition of uniform magnetisation as is practically attainable. In some cases rings were used in a manner similar to that employed by Stoletow and Rowland, except that in the present case the process of magnetisation was effected in a series of sudden steps, the total magnetisation being found by summing up the inductive effect of the steps. In most cases, however, the author used straight pieces of wire, whose length was 300 or 400 times their diameter. These permitted the use of a direct magnetometric method of observation, and consequently the magnetising force could be applied and removed continuously and slowly, instead of by sudden steps. Preliminary experiments had satisfied the author that wires of this length gave as near an approach to uniform magnetisation as could be practically obtained by using rings.

Curves are given which show the behaviour of iron and steel in various states of temper, when subjected to a first application of magnetising force, and also to subsequent cyclic changes of magnetising force, such as complete or partial removal and re-application, or reversal. The curves are drawn by plotting either $\mathfrak{I}$, the intensity of magnetisation, or $\mathfrak{B}$, the magnetic induction, in relation to $\mathfrak{H}$, the magnetising force. The characteristics of these curves and their relation to the physical state of the piece under examination are pointed out. Curves so drawn invariably exhibit the static lagging action to which the author (in a former paper) gave the name "hysteresis," any cyclic change of $\mathfrak{H}$ giving rise to a more or less nearly closed *loop* in the curve. Attention was previously drawn to these loops by Warburg, who also anticipated the author in pointing out their important physical meaning, namely, that the area of a loop, or $-\int \mathfrak{I}\,d\mathfrak{H}$, is the measure of the energy expended (per unit of volume) in performing the cycle of magnetisation which the loop describes. In the present paper numerous absolute measurements of this energy are given, especially of the energy which is thus dissipated in each reversal of the magnetism of a piece of iron or steel. These show that while the dissipation of energy by reversal of magnetism is very much smaller in soft iron than in hard iron or steel, even in the latter its amount is very trifling, so that the principal part of the heat which is produced in the cores of

* Abstract of paper read before the Royal Society, January 8, 1885.

Digitized by Google

electro-magnets must be due chiefly to other causes than this static hysteresis, and is, in fact, due almost wholly to the induction of so-called Foucault currents in the cores. The relation of this hysteresis to Weber's theory of molecular magnets, as extended by Maxwell, is discussed, and the insufficiency of Maxwell's extension noticed.

By vibrating a piece of soft iron during the application and removal of magnetising force, the effects of hysteresis are almost entirely removed, and the iron is then found to possess almost no retentiveness. But when the application and removal of magnetising force are effected without mechanical disturbance, the retentiveness of soft iron is found to be even greater than that of steel. In some cases 93 per cent. of the whole induced magnetism of a piece of annealed iron was found to remain on the complete removal of the magnetising force. It is pointed out that there is no discrepancy between this result and the well-known fact that a *short* iron core of an electro-magnet retains almost no magnetism when the current in the magnet is interrupted. In that case the ends of the magnet itself, after the interruption of the current, exert a sufficient reversed magnetising force to destroy almost entirely the residual magnetism. But when tested under the conditions which give uniform magnetisation and avoid the demagnetising influence of the ends, soft annealed iron is more retentive than even the hardest steel.

Examples are given showing that the influence of permanent set in the curve of magnetisation is so marked as to give a criterion by which a strained piece may be readily distinguished from an annealed piece of metal, and that strain diminishes very greatly the magnetic retentiveness of iron.

Numerical values of the coefficients of permeability (μ) and of susceptibility (κ) are given for a number of samples of iron and steel, and the relation of these coefficients to $\mathfrak{B}$ and $\mathfrak{H}$ is exhibited graphically after the manner of Rowland. The greatest value of μ refers to soft annealed iron while under mechanical vibration, and is about 20,000.

The next part of the paper deals with the effects of stress (consisting of longitudinal pull) on the magnetic susceptibility and retentiveness of iron, and the subject is taken up in two different ways. In one the magnetic effects are observed when a load hanging from the wire under examination is gradually applied, removed, and otherwise varied, the wire being then either kept in a magnetising field of constant value, or freed from all magnetising force. In the other method the load is kept constant, and magnetising force is applied, removed, and otherwise varied. The two methods give results which would be identical were it not for (1) hysteresis in the relation of magnetism to load, in a constant field, and (2) hysteresis in the relation of magnetism to field, under constant load. The relation of magnetism to varying load in a constant field is examined at great length, both in soft annealed wire, and in wire hardened by stretching, and the effects, which are very complex, are exhibited graphically. They also afford an easy criterion by which a stretched piece can be distinguished from an annealed piece, and, both in stretched and annealed metal, they exhibit static hysteresis, which can be more or less completely wiped out by mechanical vibration. The connection of the author's present work with the earlier results of Villari, and the extensive researches of Sir W. Thomson, is pointed out.

Numerous curves are given, showing the relation to $\mathfrak{H}$ to $\mathfrak{B}$ when the process of magnetisation is conducted while the piece under test is maintained in a constant state of stress. These show very clearly the position of what Thomson has called the "Villari critical point," or point at which the sign of the effect of stress on magnetism becomes reversed; and it is shown that this reversal is associated rather with a particular value of magnetisation than with a particular value of magnetising force, the same reversal being found to occur when the magnetism dealt with is wholly residual.

Instances are given of very curious molecular reminiscences of previous loads, which were found to exist even when the previous loading had been performed at a time when the metal was entirely destitute of magnetism, and although the loads whose effects were found to remain were much less than loads previously applied to the same wire, and were consequently unable to produce mechanical change of any ordinary kind. These residual effects of former loads became visible on the next magnetisation of the piece. It is shown that these effects of previous loads can be almost obliterated by subjecting the wire to vibration before beginning to magnetise it.

The ratio of residual to induced magnetism in soft and hardened iron and steel has been examined for various degrees of magnetisation, with the result of showing that the ratio passes a maximum when the magnetisation is moderately strong, and then falls off as the state of so-called saturation is reached. The influence of the presence of stress on this ratio and on residual magnetism generally has also been investigated.

The last part of the paper deals more briefly with the effect of temperature on magnetism, a subject already largely treated by G. Wiedemann and others. The present experiments were specially directed to discover whether there is hysteresis in the relation of magnetism to temperature when the temperature suffers cyclic changes. Careful experiments on both induced and residual magnetism have led the author to conclude that within the range of temperature dealt with by him there is no perceptible hysteresis in the relation of magnetism to temperature. Curves are also given exhibiting the process of magnetising the same piece at different temperatures. These cross each other in the same manner as the corresponding curves for different values of stress, a fact to be anticipated from the earlier discoveries of Baur.

The experiments, which have been of a very extended character, were made during 1881-1883 in the laboratory of the University of Tokio, Japan, with the help of Japanese students, Messrs. Fujisawa, Tanakadate, Tanaka, and Sakai, to whom the author is indebted for much valuable assistance. The results have been, almost without exception, reduced to absolute measure, and are for the most part presented graphically in curves which accompany the paper.

REPORT ON ELECTRIC LIGHTING IN THE CITY.

The following report, by W. H. Preece, F.R.S., will speak for itself:—

To the Streets Committee of the Honourable the Commissioners of Sewers of the City of London.

Gentlemen: On the 20th September, 1883, the Commissioners sanctioned a proposal that I made to make certain experiments to determine by calculation and by experiment the best distribution of glow lamps to light up efficiently our streets and narrow thoroughfares. I had previously pointed out the relative advantages and disadvantages of arc and glow lamps for this purpose. The light of the glow lamp is constant, steady, and uniform. It lends itself to an even and regular illumination of streets. It requires no personal attention, no adjustment, no cleaning. It can be turned on and off in an instant. Though it enables the existing posts used for gas to be utilised, it can be fixed anywhere, and it enables us to carry out practically the theoretical solution of the difficult problem of the proper distribution of light. I have already indicated, in a preliminary report, the character of the experiments that I have been carrying out in the city, and in Wimbledon, and I will now deal with them more fully under the following heads:—1. The measurement of light. 2. The distribution of light. 3. The measurement of electricity. 4. The distribution of electricity. 5. The cost of production. I will also deal with the questions of domestic, central station, and street lighting.

1. The Measurement of Light.—To measure the intensity of a source of light is a very simple matter when we have a darkened room and a reliable photometer; but to measure the light in a street, or in a hall, when it emanates from many sources, when these sources are fixed in many positions, and at various distances, and when it falls at different angles, is a very difficult thing. The present position of photometry as practically applied to electric light illumination is by no means in a satisfactory condition. I felt that to meet the difficulty we must not depend upon any direct comparison between the light emitted by a source to be measured, such as a gas lamp, and any given recognised standard of light, such as a British standard sperm candle; but that we should rather make our standard of comparison an area illuminated to a given intensity, whatever and wherever be the source of light. We do not want to know so much the intensity of the light emitted by a particular lamp as the intensity of illumination of the surface of the book we are reading, or of the paper on which we are writing, or of the walls upon which we hang our pictures, or of the surface of the streets and of the pavements upon which circulates the busy traffic of cities; we want to know in fact the degree of illumination due to the emitted light, not the intensity of the rays of the source of light. Illumination of this character depends as a rule not on one source only, but on many sources of light, distributed in innumerable ways. Hence to obtain reliable information as regards the illumination of our streets, I proposed to measure the illumination of surfaces quite independent of the sources of light by which they are illuminated. It was necessary in the first place to determine some standard of reference by which comparisons could be made, for all systems of measurement are simply numerical comparisons with some unit taken arbitrarily as a standard. We measure distances by reference to the *yard*, weight by reference to the *pound*, time by reference to the *second*. We know the effect on our eyesight when reading in bright daylight, or dull twilight, or moonlight, and in gas light, or the light of oil and that of candles. In a dull lighted room we are often obliged to increase the illumination of the surface of the book we are reading, by lighting an additional candle or bringing the lamp very near the book. A sperm candle burning at the rate of 120 grains per hour is the parliamentary standard of light in England. In France it is the light emitted by a Carcel lamp burning 42 grammes of pure colza oil per hour with a flame 40mm. high. A single British standard candle placed at about a foot distance, or a French standard lamp at a metre from the page to be read, gives a very fair amount of illumination. As the metrical system of measurement is being gradually introduced into this country, and our relations with foreign manufactures and measures are becoming more and more intimate, it was very desirable to establish a standard that would be applicable to both systems and in all countries. I made my standard the amount of illumination given by a British standard candle fixed at 12·7in. distance. This is very easily reproduced, and it is the same illumination as that given by the French standard light when fixed at a metre distance. It is the same illumination as that given by a steady gas flame burning 5 cubic feet per hour in London when fixed at 3·96ft. distance, or by a 20-candle incandescent or glow lamp at 4·75ft. distance, or by a 1,000 candle-power arc lamp at 105·8ft. distance. In terms of this standard the illumination at the foot of our ordinary street gas lamps, when the burner burns perfectly, is 0·1, while that at the foot of an ordinary arc lamp is 1·8. If we were to give such a standard a name such as *lux*, then the light at the base of a gas lamp post is one-tenth of a lux or a *decilux*, while that at the foot of a Brush arc is 1·8 *lucea*. Having thus established a standard for comparison, it was necessary to devise an instrument to measure with, or to determine the arithmetical ratio between the light to be measured and this standard. Our instrument for the purpose must be light and portable, for it had to be moved about the streets. It required to be easily reproducible at any time and place, and to be absolutely uniform. I took my idea from the fairy lamps used at the Savoy Theatre in "Iolanthe." Here we had something portable, adjustable, uniform, and very easily manufactured. One of these lamps was placed inside a small box, the top of which had a screen of white paper on which was a grease spot. I was able, by increasing or diminishing the current of electricity producing the light, to vary the illumination of one side of this grease spot. When it was desired to measure the illumination of any space, such as the surface of a street, this box had simply to be put at the place to be measured, and the current had

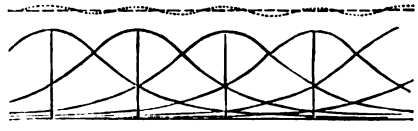
Digitized by Google

to be regulated until the grease spot disappeared. The current of electricity then became the measure of the illumination, and a simple table gave the result in terms of the new standard. The apparatus proved to be so useful, so novel, and so valuable, and it brought out so new and unexpected a law in the behaviour of the current, that I brought the matter before the Royal Society. Several forms of apparatus had to be made before I obtained one which fully met all practical requirements. Before giving results of these measurements, I must deal with the next point.

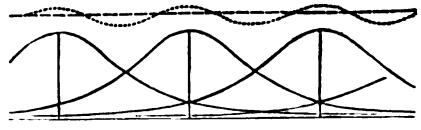
2. The Distribution of Light.—The amount of illumination received by a surface is dependent on the intensity of the source of light, and on the angle of the incident rays. The intensity of the light diminishes as the square of the distance increases, and also as the cosine of the angle which the luminous rays make with the normal to the illuminated surface diminishes. Hence, the practical illumination of our streets is not a very easy question to solve when uniformity and efficiency are desired. We can have either a few intense lights, like the arc electric light, fixed at considerable distances apart, or we can have numerous small lamps distributed about at very short intervals. In the first case we must have either very imperfectly illuminated intervals, or we must have an enormous waste of light; in the second case we can have a fairly uniform distribution of light, if due regard be paid to the laws regulating this distribution. The more intense the light, and the greater the distance apart, the greater the loss and the waste. It was desirable to find out how light was distributed in our street, and then how best it could be done by glow lamps.

The Distribution of Light in our Streets.—The Brush arc lamps are fixed at a height of 15ft. from the level of the pavement, and at a mean distance apart of 150ft. They are nominally 1,000 candle-power lamps, but the mean average intensity of the light they actually emit is by measurement 400 candles. The gas lamps are fixed at a height of 12ft. from the ground, and in the main thoroughfares at a distance of 66ft., measured diagonally across the street. Their nominal candle-power is 14, but their average actual intensity is 10 candles. The Edison glow lamps on the Holborn-viaduct were fixed at the same height and in the same position as the gas. There were some nominal 32 and some nominal 16 candle-power lamps, but their actual mean intensity of light was only three-fourths of this. The simplest method to indicate the way in which these lamps distribute their rays is by a curve, the height of which above the ground-line at any spot indicates the intensity of illumination at that spot. The following curves are the results of actual measurements, and indicate the degree of illumination at different distances from the source of

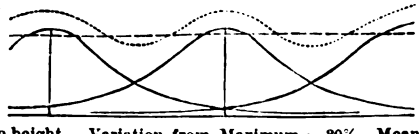
Diagram 1.



Distance apart = the height of the light from the ground. Variation from Maximum = 4%. Mean illumination 1·8 times Maximum of one lamp.



Distance = 1½ times height. Variation from Maximum = 16%. Mean illumination = 1·2 times Maximum of one lamp.



Distance = twice height. Variation from Maximum = 30%. Mean illumination = 0·9 of Maximum of one lamp.

light. The distribution of light on the surface differs of course very materially with the mode in which light is reflected or refracted. Three-fourths of the light emitted by a naked lamp are absolutely wasted as far as the street is concerned; it is lost in the sky. When the intensity of the light is too great for the eyes to bear with comfort, the barbarous practice is in vogue of destroying 50 per cent. of the remaining fourth by covering the light with an opaque, or semi-transparent shade. A good arc lamp should give an intensity of at least 1,000 candles per horse-power, but those in use are often toned down by absorption and obstruction to less than 250 candles. This means wasted energy and a proportionately larger coal or gas bill to pay. The uniform distribution of light over the surface of a street means the utilisation of those rays that are now wasted upwards in the air, and their diffusion without unnecessary loss by absorption. Very rough and unscientific modes of doing this have been attempted by the gas and electric light companies, but with very little success. The light is still distributed in bright patches, which are separated by dark intervals. Gas light must necessarily be enclosed in a lantern which, while it supplies air for combustion, checks draughts and currents which lead to imperfect combustion. It therefore does not lend itself so much to scientific distribution as the electric light, which can be fixed anywhere and anyhow. The question has been most ably and scientifically attacked by Mr. A. P. Trotter, who has produced a dioptric lantern that merits the most careful consideration and examination. It is quite possible, theoretically, to take a light at a given distance from the ground, and so to divert the rays that are now wasted, as to uniformly distribute or spread them over a circular area, whose diameter is many times the height of the lamps. Mr. Trotter has applied to street lamps the same principles that are so effective in our lighthouses in converging all the rays upon a horizontal plane. He makes clear flint glass globes or lanterns of such patterns and shapes that the rays of light are diverted and reflected as shown in Diagram 2.

Diagram 2 shows the influence of this dioptric lantern in spreading the light. The black curve shows the natural diffusion of the unobstructed rays of light; the dotted curve shows the effect of opal globes, or opaque shades; the straight horizontal line shows the effect of the distributing system by means of the dioptric system. The areas embraced by these curves indicate the comparative economy of the different modes. It is seen how wasteful is the obstructive or shaded system. The eye is affected directly by the intensity or quality of the light. It does not take in the quantity of light emitted. The height of the vertical line in these curves gives the intensity at any point, and it indicates how the eye is affected at those points. Thus it shows that, while the dioptric prism apparently lowers the intensity, it spreads the quantity over an enlarged area. Hence it is that when the eye alone estimates the value of the dioptric lantern it is deceived, and it is only scientific measurement by photometers that enables a true conception to be formed of the efficiency of the system. There are other modes of attaining the desired object of distributing usefully the present wasted rays by scattering or reflecting them from white bright surfaces. Many experiments were made at Wimbledon in this direction. The economical distribution of light is largely effected, as I have shown, by its diffusion, but the practical problem as regards our streets is determined more by the amount and degree of light emitted by each lamp, by its height above the ground, and by its position along the street. The illumination of any point is the resultant, or combined effect of all the neighbouring lamps whose rays fall on that point. It is very easy to calculate this resultant when the number of lamps is few, and still simpler to show the result by diagram. Diagram No. 1 shows this distribution when the lights are fixed at various distances apart, and arranged quincuncially, that is, like the five of diamonds, or any other suit of cards. When the distance apart is twice the height of the lamp, there is a variation of 30 per cent., and at three times the height, 60 per cent., but with the dioptric lantern the distribution is practically uniform. It is very easy to show that, from an economical point of view, in an unrestricted space and under ordinary circumstances, it is cheaper to have one bright

Diagram 2.

light, say a 1,000-candle arc lamp, fixed high up in the air, than several smaller lamps, say 20 fifty-candle glow lamps fixed at a lower level; but we are not now dealing with the question of cost, we are considering only the uniform distribution of light, so as to illuminate our streets with the greatest efficiency. The following table is calculated to show the theoretical distribution of light from different sources:—

	Arc lamps 20-ft. post.			Glow lamps, 12-ft. post.	
Candle-power (nominal)	1,000	500	.....	20	50
Horse-power	1	0·75	.....	0·1	0·25
Area illuminated in acres	0·353	0·353	.....	0·1	0·1
Horse-power per acre	2·83	2·12	.....	1	2·5
Length of street, feet	172	172	.....	60	60
Horse-power per 100 feet	0·58	0·435	.....	0·167	0·41
Maximum illumination in luces	2·5	1·25	.....	0·139	0·348
Minimum ditto	0·055	0·0275	.....	0·011	0·0275
Mean ditto	0·41	0·205	.....	0·023	0·0575

As a matter of fact, the mean actual illumination of the arc lamp, owing to obstruction and absorption, is only about one-fourth of the calculated, and the mean actual illumination of the glow lamp by reflection and refraction is twice that calculated. Hence the mean illumination of the 50 candle-power glow lamp and that of the arc may be about the same.

3. The Measurement of Electricity.—No proper conception of the economical production of the electric light can be arrived at without careful and accurate measurements of the quantities of electricity used. Dynamo machines are now brought to such a state of perfection that their commercial efficiency can be determined to an accuracy of 1 per cent. Thus the ratio of the useful work done outside the engine room to the work put in inside can be so accurately determined and even guaranteed by manufacturers, that when once we can measure the strength and potential (or pressure) of the electric currents flowing in the circuit we can calculate the quantity of coal that should be burned in the furnace to produce them. There are no physical quantities that can be determined with such marvellous accuracy as electrical effects, but curiously enough the more minute these quantities the more accurate the result, and the larger they are the more difficult the measurement and the less reliable the apparatus at our command. The measurement of gas or water used for any purpose is very easy. Meters are made which record accurately the quantity of each fluid flowing through, whatever be the pressure, and which record therefore the rate of flow, but in using electricity we require to know the pressure producing the flow, and the strength of the current, or the rate of this flow, to determine the energy consumed, or the work done in the circuit. Gas passes through the meter and is all utilised—a little may leak, but its presence is soon detected. Electricity, however, may be wasted in an unknown and unseen manner, unless a careful watch is kept on its performance. It was therefore essential that an accurate measurement of the electrical pressure and of the strength of the electric currents used should be determined. The pressure is expressed in terms of a unit called a *volt*, which is about the electromotive force of one cell of an ordi-

Digitized by Google

nary Daniell battery, and the strength of the current is expressed in terms of the ampere, which is about the current used in an ordinary 20-candle glow lamp. The product of these two quantities, or the volt-amperes, which is the measure of the rate at which energy is consumed in the circuit, or of the power expended, is expressed in terms of the watt. The watt is a most valuable unit of power for electrical purposes. A horse-power is too large a unit of power. The watt is 1-746th part of a horse-power, or in other words, the horse-power is equal to 746 watts. A man rowing a race exerts about 100 watts, while in ordinary work, such as turning a handle, he works at the rate of about 60 watts. A sperm candle while burning develops about 90 watts—a man's power—while a common gas lamp develops 67 watts per candle. An arc lamp develops only 1 watt per candle, while the best glow lamp of the present day develops about 2·5 watts per candle. Hence the little heat produced by the electric light and the wide field for economy there is in its production. Few realise the waste of energy in gas light, or consider its proper function, viz., the production of heat and of power. The practical instrument used to measure the electrical pressure is called the *Volt meter;* that to measure the current the *Ampere meter;* that to measure the energy consumed the *Watt meter*. Absolutely reliable instruments of these kinds have not yet been produced, so that where accuracy is essential laboratory experiments must be made. There are many kinds of instruments in the market; too many in fact. Every engineer seems ambitious to devise a new form. This is perhaps one proof of their want of reliability. Of Volt meters I have used:—Sir William Thomson's, Cunynghame's, and Cardew's; of current meters:—Siemens', Thomson's, Ayrton and Perry's, Cunynghame's, and Upperborn's. Of Watt meters I have used none, for I have obtained sufficiently accurate results by multiplying together the volts and amperes. Some of these instruments, though equally practical and useful, required frequent verification and calibration in the laboratory. For simplicity, accuracy, and constancy, Cardew's volt meter leaves nothing to be desired, and latterly it was the only one I used. For large currents nothing can surpass Thomson's or Siemens', while for smaller currents Ayrton and Perry's is admirable. As an example of the mode of taking electrical measurement, I give the following results:—

Wimbledon, 20th May, 1884. Three 50-candle Woodhouse and Rawson lamps in one group.

Observation.	Electromotive Force in volts.	Current in Amperes.	Watts per lamp.
1	52	7·5	130
2	52	7·5	130
3	56	6·9	128·8
4	56	6·9	128·8
5	48·5	7·8	126
Mean per lamp.....	52·9	2·4	128·7

4. The Distribution of Electricity.—By this term is meant the arrangement of generators, conductors, and lamps, so as to obtain steady light with the least expenditure of energy, the smallest weight of copper, and the most economical form of lamp. Steadiness of light depends on constant pressure, and this is now obtained without any difficulty by perfectly governed engines and compound-wound machines. It is also obtained by using secondary batteries as regulators. The crux of electric lighting consists in its mode of distribution. The Electric Lighting Act of 1882 contemplates three modes of distribution, viz., the Series, the Parallel, and the Charging systems. A familiar type of the first—the Series system—is the Brush arc system, as used in the city of London, where as many as 40 arc lamps are joined up in series, or succession, on one continuous wire. An example of the second—the Parallel system—is found in the Edison installation on the Holborn Viaduct, where two thick main wires are carried through the area illuminated, and smaller leads are tapped off these conductors in a parallel fashion to act as minor conductors to each house, and again to each room, and again to each lamp. I know of no practical example of the third system as defined in the Act of 1882, though an important modification of it has been introduced into Colchester, to which I shall refer. The Series system is limited in its application. It has the disadvantage that, if one link in the chain breaks down, if one lamp goes out, all must simultaneously become extinguished, for the current will be stopped, unless special apparatus, acting automatically, cuts out each lamp as it fails, and thus restores the circuit. It involves the use of high tension currents, and therefore it means danger to person, unless perfectly protected. It has, however, the great merit of requiring light or inexpensive conductors. It is inapplicable to the ordinary incandescent system, though, as I shall show, a new glow lamp—the Bernstein—can be worked on this plan. The Parallel system is unlimited in its character, though the weight of the conductors increases as the area illuminated increases, in an increasing ratio which renders it impracticable to apply this system to any but small districts. An eminent consulting electrician recently pointed out that to supply an area requiring 100,000 lamps it would be necessary to have two copper bands nearly 31 yards wide and ·4in. thick. Such conductors would weigh 3,950 tons, and cost £1,500,000 per mile. If in full work they would actually waste energy at the rate of 6,750 horse-power, costing £65,000 per mile per annum. Such enormous conductors and such fearful waste render the parallel system pure and simple financially impracticable. The charging system is a system of decentralisation. It contemplates the use of currents of very high tension—4,000 volts—generated in a central station and conveyed along conductors to sub-centres, where they are employed in charging or exciting secondary batteries or accumulators, used as a store of energy, for the purpose of further distribution at a lower pressure into the houses on either the series or parallel system. The charging system, if it were practical, would remedy all the defects of the parallel system. High tension currents render small conductors practical, because they involve the use of small currents, but unfortunately the use of secondary batteries as accumulators has not yet been proved to be a practical success, and therefore this system has not yet had a fair trial. Were these batteries to prove successful, nearly all the difficulties in electric lighting would vanish. A wire the size of a lead pencil would replace the massive conductors required by the parallel system, and electric lighting would become a financial success. There are certain modifications of these systems of distribution which require examination. Dr. Hopkinson in England, and Mr. Edison in America, have considerably diminished the costliness of the parallel system by joining up two dynamos in series, and by introducing a third wire between them, which has allowed twice the electromotive force to be employed. It has thus diminished the total

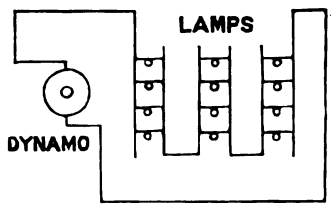


Fig. 1.

weight of copper used by five-eighths, that is, three-eighths of the copper required by the simple parallel system is all that is now needed for this new system. All central station systems put up by Mr. Edison in the United States are, I am told, installed on this plan. I do not know of its use in England. Indeed, there is no central station now at work here. This principle of multiple conductors admits of considerable extension. Dr. Fleming has shown that the economy effected is given by the formula:—

$$\frac{M}{2(M-1)^2},$$

M being the number of conductors, so that if five conductors were used, only 5·32 of the copper which would be required by the simple parallel system would be necessary. There is another serious difficulty in distributing electricity practically, and that is the diminution of electric pressure as the distance increases from the source of power, or as the number of lamps used varies. Lamps of different qualities have to be used in different parts of the circuit, if on the parallel system, to maintain equal efficiency. Thus, while on the Holborn Viaduct 110 volt lamps were used, at the General Post Office 90 volt lamps could alone give an efficient effect. There are two modes of distributing currents in practical use on a small scale, which tend to remedy these defects, the one at Brighton by the Hammond Company, and the other at Colchester by the South Eastern Brush Company, the one at Brighton being regulated by electro-magnetic devices, that at Colchester by secondary batteries. The system in use at Brighton is called the grouping system. It was introduced at the Paris Exhibition of 1881 by Mr. Henry Edmunds in applying a Brush dynamo to light up a large number of Swan glow lamps in the Congress Hall. It is a combination of the series and parallel systems. Supposing a dynamo producing 2 000 volts and 10 amperes were used to illuminate glow lamps requiring 50 volts and 1 ampere to incandesce them, then by this system groups of ten lamps would be joined up in series of forty steps, as in Fig. 1.

Now if the dynamo be self-regulating, as all good dynamos should be, then if any group of ten lamps be suddenly extinguished without breaking the circuit no injury or inconvenience would ensue. On the other hand, if any one lamp of the group be broken accidentally, or extinguished purposely, then too much current would pass through the remaining nine lamps; their existence would be endangered, and if they all went out, the whole circuit would be broken, and all the lamps throughout the whole circuit would be extinguished. This happened, as will be shown further on, in Wimbledon. Very ingenious electro-magnetic devices are used in Brighton to throw other lamps or equivalent resistances into the circuit when any one lamp fails. Of course, where very high tension currents

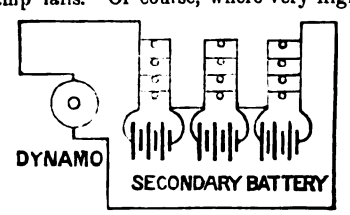

Fig. 2.

are used, there is danger to person if accidental contact is made with the wires conveying the currents; but this danger is reduced to a minimum when the wires are carefully insulated, and where the use of the earth is eschewed. The Board of Trade limits the electromotive force inside a house to 200 volts, but in the group system, while the total electromotive force may be 2,000 volts, it would be practically impossible for a person to touch two conductors at a higher potential with respect to each other than 50 volts. Circumstances might arise when, by the accidental use of the earth, the whole electromotive force might act on a person, but this is a contingency even more remote than that of a person walking deliberately with a lighted candle into a room full of explosive gas. A very important modification of this grouping system was used at Wimbledon, in which plain, cheap, and simple secondary cells were used as regulators

Digitized by Google

instead of electro-magnets, as at Brighton. Each group had in addition to its quotum of lamps 25 secondary cells, connected as in Fig. 2.

At first the whole of the current would pass through the cells, in consequence of their low resistance, but it would speedily generate a counter electromotive force, and as soon as this electromotive force reached the maximum of the battery, which was that required to incandesce the lamp, the whole of the current would then pass through the lamp, and none through the battery. If a lamp broke, then the excess of current would pass through the battery, for the battery would prevent the raising of the electromotive force at the terminals of the lamps, which would be necessary to send more current through them, and therefore the current through them would remain steady. This quality of secondary cells is as valuable as their so-called storage power, and it requires only to be understood to be used. The system in use in Colchester is called the B. T. K. system, from the initials of Messrs. Beaman, Taylor, and King, who introduced it. Two large brush machines (known as No. 8), fixed in a central station, are used to charge secondary batteries placed at six different distributing points in the town. The houses and shops are supplied direct from these batteries. The automatic arrangements devised to stop charging when the batteries are full, and to direct the charging current to a second battery, are very ingenious. In fact the whole system has been worked out well, and it is an experiment that deserves very careful watching. I must confess, however, that at present I have no great faith in the commercial use of the present secondary batteries for the storage of electrical energy. As regulators they are already nearly perfect. Nevertheless, it is impossible to predicate what may be done with them. A novel and remarkable system of distributing by secondary generators, that of Messrs. Goulard and Gibbs, has recently been tried for a short time on the Metropolitan Railway. It is a modification of the charging system without the power of storage. A powerful alternating current dynamo, giving 1,500 volts and 11 amperes at one station—the Edgware-road—excited large induction coils or secondary generators at five other stations where secondary currents were employed to light up and regulate glow lamps in and about the stations. One hundred and fifty-one glow lamps and five Jablochkoff candles were distributed over a circuit eight miles long. The results obtained were surprising, and the efficiency of the apparatus proved to be very good. In selecting a mode of distribution for practical trial at Wimbledon, I had to take into careful consideration all the advantages and disadvantages of these different systems, and to select that which seemed to be the least objectionable. I had also to decide upon the use of a proper dynamo. The choice of a dynamo rested between alternate and direct current machines of high and low tension, some admirable examples of each of which are now to be obtained. The Ferranti alternate current machine is one of the most perfect machines, mechanical, and electrical, which has yet been manufactured, but it does not produce high enough tension for the purpose I had in view. In fact, my choice rested between the Brush and Hochhausen, and I chose the latter because its currents were more uniform and its efficiency apparently higher. This machine was exhibited at the Fisheries Exhibition of 1883 for the first time, and its performance there was very striking. Its behaviour has been admirable, and I am very well satisfied with it. The mode of distributing that I adopted was the grouping, each group being regulated by a secondary battery, as shown in Fig. 2. The working was very successful; the secondary cells kept the electromotive force of each group constant. If any lamp failed, the excess of current would pass through the cells, and not through the other lamps, whose light would remain steady and constant as long as only one lamp remained. Another advantage was that different kinds of lamps could be used at the same time. A current of 10 amperes was used, and this might pass through 10 lamps on one group, giving an ampere to each, or through five lamps taking two amperes each, or through one lamp taking 10 amperes, or any arrangement that would altogether take the whole current, the choice of the lamps for each group being quite independent of the electromotive force, as long as they required the same electromotive force in each group. This question of the proper distribution of currents is one of momentous consequence to the future of electric lighting, and it is one that is still in a tentative state. The Act of 1882 defined modes that are now obsolete. It is very necessary to watch carefully the result of the experiments that are being made at home and abroad, and I propose during my forthcoming visit to America to examine very carefully what has been done there. Unless a mode of distribution requiring light conductors can be proved to be practical, the financial success of electric lighting on a large scale is impossible.

5. The Wimbledon Experiments.—It was to determine the cost of production and to test practically the question of the measurement and distribution of light and of electricity for public street purposes that the experiments at Wimbledon were carried out. A commodious shed was arranged and placed at my disposal for an engine and dynamo room by the Local Board of Wimbledon. A portable agricultural steam engine of eight horse-power (nominal) was hired from Messrs. Wallis and Steevens, of Basingstoke. It was one of their standard pattern engines fitted with sensitive governors, such as is used at the British Museum for electric lighting purposes. The engine worked admirably and gave much satisfaction, but it was used far below its actual capacity, and therefore its consumption of fuel was not economical. This engine was connected by American oak tanned belting to a No. 4 Hochhausen dynamo machine, which was lent for the purpose by Mr. Henry Edmunds. The engine house was supplied with all the requisite meters and indicators to enable the electrical pressure and currents to be read at any moment. Two circuits, partially of solid No. 8 copper, and partially of stranded copper wire, made up of seven No. 16's, and giving a resistance of two ohms per mile, were supported on insulators fixed on ordinary scaffold poles placed at regular distances of 100ft. apart. The wire was lent for the purpose by Messrs. W. Glover and Co. The upper circuit extended through the Broadway, and up the hill to the High-street. The lower circuit extended through the Broadway, down the Merton-road and Gladstone-road, returning to the station by the Hartfield-road. Each circuit was about three-quarters of a mile long, and three miles of wire altogether were employed. The following table indicates the order and character of the experiments which were carried out:—

No. of Experiment.	Upper Circuit.	Lower Circuit.
1	20 c.-p. Swan lamps at 100ft.	20 c.-p. lamps at 100ft.
2	20 c.-p. Swan lamps at 200ft.	20 c.-p. lamps at 100ft.
3	10 c.-p. Swan lamps at 100ft.	20 c.-p. lamps at 200ft.
4	20 c.-p. Woodhouse and Rawson lamps at 100ft.	10 c.-p. lamps at 100ft.
5	50 c.-p. Woodhouse and Rawson lamps at 300ft.	10 c.-p. lamps at 100ft.
6	50 c.-p. Woodhouse and Rawson lamps at 200ft.	10 c.-p. lamps at 100ft.
7	50 c.-p. Woodhouse and Rawson lamps at 100ft.	10 c.-p. lamps at 100ft.
8	Bernstein lamps of various powers at different distances.	10 c.-p. lamps at 100ft.
9	Maxim lamps of various powers at different distances.	10 c.-p. lamps at 100ft.

A yard was especially set apart for experimental purposes, and each kind of lamp separately and carefully measured under various conditions. It would be tedious and unnecessary to describe in this report in detail all that was done and all the measurements that were taken. The programme was rigidly carried out. It will be more profitable to consider the results attained. No particular care was exercised to secure economy in the engine room. It is difficult to attain this in a temporary installation with an engine not specially designed for the work it is intended to do. Moreover, the expenditure involved in obtaining electrical power is so accurately known that there is no difficulty involved in getting it contracted for at a fixed price known to be just and fair, and therefore there was no object to be gained in studying carefully the efficiency and economy of the motive power arrangements. Horse-power developed by the engine can be converted into a definite number of electrical watts in the circuit, the cost of whose production is known, and to supply which responsible contractors could be found.

(TO BE CONTINUED.)

TELEGRAPHIC COMMUNICATION WITH THE EAST.

The following discussion on this subject took place in the House of Lords on Tuesday:—

Viscount Sidmouth asked whether the attention of Her Majesty's Government had been directed to the fact that the sole method of telegraphic communication with Hong Kong and some other British settlements in the East was by wires passing through a territory in the possession of a foreign Power; and whether it was the intention of Her Majesty's Government to adopt immediate measures to insure the safety of intercourse by electric telegraph with those parts. The question, he said, was one of great importance, and he hoped the Government had given their best attention to it.

The Earl of Derby said the noble Viscount was probably aware that there were two alternative lines of telegraphic communication between this country and Hong Kong. One of these lines passed through Russian territory in Siberia and down the Chinese coast to Hong Kong, and the other, from England to Singapore, which was more generally used, passed through Saigon, the French settlement, to Hong Kong. It was true that both these lines passed through foreign territory, but they did not both pass through territory belonging to the same Power; and if by any unfortunate event communication by one line was cut off there would still remain the other. He did not deny that there were advantages in having the entire line of communication in our own hands, but it made a considerable difference when we were not dependent on one line, but had the choice of two alternative routes not passing through the same territory. There was at the present time under the consideration of the authorities a proposal to make a line direct from Singapore to Hong Kong. That proposal was being considered by the various departments concerned, but he was authorised by his noble friend the First Lord of the Admiralty to say that the naval authorities, while not denying that such a line would be useful, did not regard it as of primary urgency, and they considered that the expenditure which would be involved might be more usefully employed elsewhere. At the same time that was the opinion of only one of the departments concerned, and no final decision had been come to by the Government as a whole. The consideration of the matter so far, however, pointed to the fact that this would be a most expensive line, as the cost of maintaining it would not be less than £20,000 a year; and in the next place, even if we had the line, it would not serve the purpose of carrying the whole communication in such a way as to avoid the territory of any foreign Power, because it would be necessary for that purpose to do that which had been often proposed—viz., to make an independent line of telegraph to Gibraltar and Malta.

The Earl of Carnarvon said that this question of submarine telegraphs ought not to be considered simply and solely on the ground as to whether the line would pay commercially. It must be remembered that these stations were valuable to this country, not only as great commercial emporia,

Digitized by Google

but they were great military and naval outposts. He did not understand one remark of the noble earl; he had spoken as if there were no submarine telegraph between England and Gibraltar and Malta. There must be a mistake in the matter, as he himself had seen it at work. He wished to call attention to an important point in connection with this matter, and that was the extreme importance at this particular moment of the Government taking every precaution in their power against these submarine telegraphs being exposed to greater risks than necessary. It should be remembered that most of our commercial transactions at the present time were begun in the first instance by telegraph, and also that nearly all these lines were worked and managed by English capital. Commercially and politically, therefore, they were English property, and deserved every consideration at the hands of the Government. He wished also to point out that in time of war these submarine lines were exposed to very great and peculiar risks, while, on the other hand, through the development of modern science they could be easily repaired. The stores necessary to repair them should be close at hand and available. He sincerely trusted that during a time of peace, when the Government had full opportunity of making preparations, they had taken the necessary steps to secure an available supply of stores. There was not a large stock of telegraphic cable in this country, but it could be manufactured very rapidly when a certain stage of the proceedings had been arrived at. The matter was a delicate one, but he thought it right to remind the House and the country that in 1878, when there were great alarms as to a Russian war, the Russian Government, who were perhaps more alive to the circumstances of the case than we were, had taken measures for cutting the submarine cables and for equipping ships for that special purpose. It was said at the time and on good authority, and was generally believed, that there was a carefully elaborated scheme for taking measures against our submarine cables in the Eastern waters. It was quite right to mention these matters now, and he trusted that the Government had not been blind to the danger of leaving them unprovided for; but that while they had had the opportunity and a full warning they had taken those steps and those measures which might be necessary at any hour. [Hear, hear.]

The Earl of NORTHBROOK was understood to say that the question to which the noble earl referred was of a somewhat delicate character, and that if he thought it necessary to bring the matter to the notice of the Government it would have been more advisable to do so by means of a private communication [hear, hear.] If by making these remarks the noble earl meant to imply that those who were responsible for such matters were not alive to their importance, he was quite mistaken: What his noble friend had said was perfectly correct. There was a line, no doubt, almost entirely in English hands, to Malta, and so on to Hong Kong. He could assure the noble earl opposite that he was quite mistaken in supposing that the Government looked on these lines only from a commercial point of view, and, if he thought so, he must have misunderstood what had been said. There was no doubt that these submarine lines had other importance than mere commercial value. He could assure the noble earl that the Government had by no means shirked their responsibility in the matter [hear.]

The Marquis of SALISBURY said that the noble earl (the Earl of Northbrook) had applied a rather severe measure of interpretation to the language of his noble friend. In the first place, the noble earl (the Earl of Derby) not only did not say that there was a submarine line to Gibraltar, but exactly the reverse.

The Earl of DERBY, who spoke in a low tone across the table, was understood to say that he stated, in reply to Viscount Sidmouth, that there was no independent line to Gibraltar and Malta.

The Marquis of SALISBURY said there was another point which had not been noticed. It was a question whether commercial considerations were to be predominant over all others in these matters. The noble earl had simply stated that the colonies were not making this submarine line to Hong Kong, and that it would cost £20,000 a year. That was the very financial consideration which the First Lord of the Admiralty repudiated. But there was a point as to which he did not know whether it had attracted the attention of the Foreign Secretary, and it was whether the duty of a neutral was fulfilled if he conveyed a warlike message by telegraph. If there was any doubt upon that point the importance of submarine lines would become very great. He was not aware whether it had been decided; but he could easily imagine that if the neutrality of any Power towards us was not very benevolent difficulties might arise.

LIGHTING THE CITY.

At a recent meeting of the Sewer Commission the Streets Committee reported as to the contract entered into with the Hammond Electric Light and Power Company for lighting a part of the City by electricity, that the second £5,000, which was to have been deposited under the contract on Saturday last, had not been paid, that Mr. Hammond appeared anxious to carry out the contract, and that if the Money Market became more settled the company would be able to raise the necessary funds. The committee therefore recommended that the time for depositing the second £5,000 should be extended to June 11th, a period of two months.

Mr. TICKLE moved the adoption of the report. He did not think this was a very unreasonable request, considering the peculiar times when the raising of money for a public purpose must be a matter of considerable difficulty, especially when it was connected with electric lighting. The committee were most anxious to get electric lighting in the City [hear, hear], and a certain district was to be lighted up by the company, and he thought the committee should know the difficulties which surrounded the carrying out of any work for electric lighting, and the committee had endeavoured to assist the company to carry out the contract in every possible way. This was not a question of merely handing over the second £5,000. That was a small portion of the cost of accepting the undertaking. This installation would cost about £80,000, and before the company deposited a large amount of money like £10,000 they must be sure that they would get this £80,000. Whether they could get it remained with the company, but the committee asked for further time that they might have the opportunity [agreed.]

Mr. E. BELL asked the solicitor whether an embargo had been laid on the first £5,000 paid by the company [cries of "Agreed!"]

Mr. MOORE thought it not a fair question. Mr. Bell could obtain that information from the solicitor privately.

Mr. BELL pressed the question. He was simply asking whether that £5,000 was free and unfettered as far as the Company was concerned. He believed it was not.

Mr. MOORE was sure the Court would desire to give every facility to the company with a view of getting electric lighting. The company had acted throughout in a most fair and candid manner, and it was to the interest of the public that it should be assisted.

Mr. ALTMAN and Mr. SHAW urged that the question should not be put, and

Eventually the report was adopted.

Removals.—We are informed by Messrs. Frederick Young and Co. that, in consequence of the increase of their business, they have decided to transfer their office, show room, and works to the Prudential Works, Greville-street, Holborn, E.C. (situated in the rear of the Prudential Assurance Company's offices), and which they will shortly open.—In consequence of the increase of their business Messrs. Eck, Callow, and Co. have decided to transfer their office, show room, and works to the Prudential Works, Greville-street, Holborn, E.C. (situated in the rear of the Prudential Assurance Company's offices), and which they will shortly open.

NOTES.

THE BERLIN TELEGRAPHIC CONFERENCE.—The opening of the Telegraphic Conference at Berlin will take place on the 10th of August.

THE AUSTRIAN TELEGRAPHS.—The Austrian Government opened on the 1st of April a new telegraph office at Fürthof, in Lower Austria.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 17th inst. amounted to £3,605.

THE TELEGRAPHS IN THE FAR EAST.—The people of Singapore are also arranging for their defence, and are pressing for torpedo boats and a direct cable.

ELECTRICITY AND MEDICINE.—During the past week an examination of the cancer in General Grant's mouth was made by means of a small incandescent lamp.

TELEGRAPH BLUE.—Not content with having given us an "electric" colour, Paris is once more to the front with a new shade of blue, called "Telegraph blue."

THE SOUDAN TELEGRAPH LINE.—The military telegraph wire has been laid from Souakin to the front, so that there is constant communication between the two points.

THE RUSSIAN TELEGRAPHS.—A telegram from St. Petersburg, dated the 23rd inst., notifies the opening of a telegraph station at Kachka, in the Trans-caspian territory.

THE EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY.—This Company notify that a mail steamer is advertised to leave Zanzibar for Mozambique on Saturday (to-day).

THE CASPIAN SEA CABLE.—A telegram from St. Petersburg, dated the 21st inst., says:—"The Caspian Sea cable is interrupted, and trans-Caspian telegrams are forwarded *vid* Persia."

THE TELEPHONE IN PARIS.—There have been opened during one week in Paris, by the Société Générale des Téléphones, nine new call offices. The number of such offices available in Paris is now 68.

THE SPANISH TELEGRAPHS.—Early on Sunday morning last the telegraph lines were cut between Madrid and Saragossa. The perpetrators have not been discovered, but no importance is attached to the incident.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th April are £3,980, as compared with £3,221 in the corresponding period of 1884.

VOLCANIC ERUPTION IN JAVA.—It is reported from the Hague that an eruption has taken place of Mount Smeroe, the highest volcano in Java. Much damage has been done to the residences and coffee plantations in the district.

SALE OF PLANT.—We are requested to draw attention to the fact that it is the surplus mechanical plant, and not the electrical plant of the "Pilsen-Joel" and General Electric Lighting Company, which is to be sold by public auction.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 17th inst. were £2,897, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

"TECHNOLOGICAL DICTIONARY."—We have received the second part—German-English—of the new "Technological Dictionary of the Physical, Mechanical, and Chemical Sciences," published by Messrs. Symons and Co., of 27, Bouverie-street, London, E.C.

SMELTING BY ELECTRICITY.—The Cowles Electric Smelting and Aluminium Company of Cleveland, with a capital stock of $200,000, was incorporated at Columbus recently. The object of the company is the extraction, by means of electricity, of aluminium on a commercial basis.

IMITATION PLATINUM.—The appearance of platinum may be given to copper by immersion in a bath composed of 1¾ pints hydrochloric acid, 7½oz. arsenic acid, and 1¼oz. acetate of copper. The article must be cleaned before immersion, and left in the bath till it has the colour of platinum.

TELEGRAPHIC COMMUNICATION WITH THE ISLE OF MAN.—The screw steamer "Monarch" is engaged laying a new cable between the island and St. Bee's Head, and telegraphic communication is entirely suspended; but the work will, it is expected, soon be completed, and communication restored.

THE AUSTRALIAN TELEGRAPHS.—A telegraph office has been opened at Wandiligong, Victoria, South Australia. Mr. H. D. Willcox, postmaster and telegraphist at Alexander South, in Vincent County, has been brought before the local court and remanded on a charge of embezzlement of public moneys.

THE ELECTRIC LIGHT AT THE PALAIS ROYAL.—A syndicate formed by the tradesmen of the Palais Royal in Paris has decided to light the shops, the galleries, and the garden by electricity. The central station in which the necessary works are to be commenced as soon as possible will be arranged for 3,000 incandescent lamps.

SIXPENNY TELEGRAMS.—Down to the time of our going to press the Postmaster General's scheme for altering the inland telegraph tariff had not come on for second reading in the House of Commons. It was understood, however, that the Bill would be withdrawn if Lord John Manners's amendment for retaining full addresses be carried.

THE MEDITERRANEAN EXTENSION TELEGRAPH COMPANY.—The liquidators of this company announce that the transfer books of the company will be closed for five days from 20th inst. prior to a distribution among the ordinary and preferred shareholders of £2 per share of Eastern Telegraph Company's Four per Cent. Mortgage Debenture stock.

THE ADMIRALTY TELEGRAPH WIRES.—The Admiralty have informed the dockyard authorities at Devonport that during the present state of public affairs the use of the Admiralty telegraph wires is to be reserved for the more immediate purposes of the fleet of vessels being got ready for sea and for other matters of pressing importance in relation thereto.

OVERHEAD WIRES.—At a recent meeting of delegates from the various metropolitan vestries and district boards of works held at Lambeth Vestry Hall, resolutions were passed declaring that it was desirable, in the interest of the inhabitants of the metropolis, and as a general principle, that all telephone and telegraph wires within the metropolitan area should be placed underground.

THE TELEGRAPH IN ARABIA.—A telegram from Jeddah, dated the 20th inst., says:—Advices from the interior state that the Turkish troops occupied in laying the telegraph wire between Mecca and Taif were recently attacked by the Arabs inhabiting the district. In consequence of this affair the Turkish Government has resolved to pay an annual subsidy to the tribes for the maintenance of the telegraph between Mecca and Taif.

THE HUGHES TYPE-WRITER.—A well-known French electrician, M. Duplay, has replaced the old system of pedal-

Digitized by Google

winding in the Hughes type-writer by a small automatic electric motor, which enables the pedals at present in use to be dispensed with. This motor is automatically placed in the circuit of a battery, or of a dynamo, at the precise moment when the weights have finished their descent, and causes them to reascend.

ELECTRIC LIGHT FOR STEAMSHIPS.—The steamship "Canada," belonging to the Compagnie Générale Transatlantique, received before her departure for Tonkin an experimental installation put in by Breguet. This consisted of 36 Edison 16 candle-power incandescent lamps, distributed in the saloon, the companion ways, the ladies' boudoir, and the smoking room. The current was supplied by a Breguet dynamo, driven by a small engine of six horse-power.

VOLUNTEER TELEGRAPHISTS AND THE WAR.—A further detachment of the field telegraphists of the 24th Middlesex (Post Office) Rifle Volunteers has been ordered to prepare for immediate embarkation for Egypt. In the event of a war with Russia it is considered probable that these men will proceed to India. The reserve corps of telegraphists from which this detachment is being drawn has recently been augmented by nearly one hundred enlistments.

BOLLMANN'S REDUCER.—A valued correspondent, writing from Vienna, informs us that amongst the apparatus upon which Mr. Bollmann is now engaged is a so-called "reducer" for effecting the conversion of currents of high E.M.F. to currents of low E.M.F., somewhat after the Gaulard and Gibbs, or, more recently, the Tipernowsky and Déri arrangements. Bollmann's contrivance, however, works with a continuous current in the primary circuit, which, on the face of it, seems to be in itself a distinct advantage.

NEW ELECTRIC LIGHTING COMPANIES.—The New Lots (N.Y.) Electric Lighting Company was incorporated at Albany, N.Y., on the 6th inst., with a capital of $15,000. The "Eastern Electric Company," with a capital of $250,000, has also been formed at Elizabeth, N.J., for the purpose of the introduction and sale of Van Depoele electric motors for surface and elevated roads. A tower 150 feet high will be constructed in the principal part of the city, the lights from which (four in number) will, it is claimed, throw a brilliant light 2,000 feet.

AN EDISON EXHIBIT AT PARIS.—At the late meeting of the Société Internationale des Eléctriciens, a minature dynamo was exhibited by the Edison Company, designed for small installations or for charging accumulators. It was capable of furnishing at 2,200 revolutions a current of 15 amperes and 50 volts at the terminals, and of lighting 20 Edison incandescent lamps of 8 candle-power. The total weight of the machine was 50 kilogrammes = 110lbs.; the intensity of the magnetic field 1,820 c.-g.-s. units; and the effective horse-power absorbed about 1·5 when at full speed.

ATTEMPTED ASSASSINATION.—An attempt to assassinate Mr. Geo. L. Masters, manager of the Telephone Exchange, was made yesterday, says the Evansville (Ind.) *Public*, of April 1st, and for a time there was much excitement in the neighbourhood of his office. Mr. Masters had been seated at his desk, and had just risen to answer a telephone call when a shot was fired through a window, passing within less than a foot of him. The ball passed through a glass partition separating his office from an adjoining room, and deeply imbedded itself in the wall beyond. The scoundrel immediately fled, and though pursued, managed to make good his escape. Mr. Masters has no suspicion as to the identity of his would-be assassin.

THE ELECTRIC LIGHTING OF THE BANK OF FRANCE IN PARIS.—It was not until after nearly three years' experience in the offices of the Bank with 180 Edison lamps that the governor of that establishment decided upon the final adoption of the electric light. That decision has resulted from its unquestionable superiority to gas. The new installation consists of two steam engines, by Weyher and Richemond, of 60 horse-power, and three Edison dynamos, of which two are of 500 lights and one of 200. In addition to this, the administration have retained the old dynamo of 200 lamps which they possessed in 1882, and which is put in motion by an engine in the printing establishment. The lamps in actual service number about 950.

LIGHT, OR DYNAMITE?—The *Pall Mall Gazette* says: Two German gentlemen arrived in London on Wednesday morning with a new invention in the shape of an electric light lamp, which they intended to submit to the chief of the Metropolitan Fire Brigade. At the Custom House, however, upon their baggage being searched, the officials thought they had come across an infernal machine, and promptly arrested the gentlemen and seized the invention. The unfortunate inventors were detained in custody all day, pending the verification by telegram of their statements. At a late hour they endeavoured to see Captain Shaw in order to explain their grievances. An appointment was made for Thursday morning, but the electric lamp had to go untested, for the officials had sent it to Woolwich.

WANTED—A NEW WORD.—Mr. Charles Curtoys, of the Consolidated Telephone Company, writes to the *Pall Mall Gazette*, as follows:—"The telephone is now coming into such general use that we begin to want a word for reference to denote messages sent, or received, by that means. Thus we have 'cablegram' and 'telegram,' or even 'wire'—all, by the way, words of rather doubtful authenticity, though answering their purpose. To meet the present requirement, I would suggest (for the purpose of discussion) 'telephoneme'—that is, 'a voice from a distance.' 'Telepnone' would be shorter, and perhaps as explicit, but means unfortunately, in some languages, the telephone itself." Our contemporary suggests, why not "telephonam," or "telepham," for shortness, as we have "telegraph" and "telegram"?

THE NATIONAL TELEPHONE COMPANY.—We have received the April list of subscribers of the above company in the Glasgow district with the important additions of the last few months. The book has been rearranged, and a description is given of some new services of a useful nature. Exchanges have been opened in Dumbarton and Hamilton, and communication can now be given with these places in addition to those formerly, viz., Greenock, Paisley, and Edinburgh; arrangements have been made with the postal telegraph department by which subscribers can receive their telegrams by telephone as well as by the usual way, and can also send their telegrams by telephone, the charge being, in addition to the usual rates charged by the Post Office, 1½d. for each message despatched, and 1½d. for each message received.

SYNCHRONOUS TELEGRAPHY.—Probably the most extraordinary proof of practically absolute synchronism was demonstrated by the experiment recently made by Mr. Delany over the line between Boston and Providence, whereby a single dot was transmitted from Boston to Providence and automatically repeated back and forth over the same wire at practically the same instant of time, travelling over different circuits in rotation backward and forward for the duration of five minutes, during which time it travelled 450,000 miles, this time, of course, being almost wholly represented by the movement of the armatures of the instruments. When we consider, however, the conditions involved in the transmission of a single dot, as in the case of the letter *e*, already referred to, the

Digitized by Google

extent of perfection of the synchronism obtained will be understood.

ELECTRICITY AND WARFARE.—We are indebted to a French contemporary for the information that the Russian Minister of Marine has given orders for the equipment, at Cronstadt, of several fast launches with a powerful electric motor which will be actuated by accumulators of a new kind, invented by an officer of the "Ivéritinoff." The launch constructed by the inventor and submitted to the Russian authorities is said to be capable of running at a speed of 20 miles per hour for five hours. Great things, says our contemporary, may be expected, more especially in regard to night operations, from armed launches of this kind, working without noise, without smoke, and without light. One very serious drawback, however, is the limited nature of the distance covered. We should have expected from a Russian inventor a motor of much more extended capabilities. One hundred miles per hour for a week would have been better and more characteristic of the nation.

ELECTRO-MAGNETIC MILLING.—Here, says the *Milling World*, is the latest idea as to electrical application. The head miller sits in a handsomely carpeted and luxuriously furnished office, his feet easily thrown up on a desk-like structure before him. Within easy reach are a series of electrical buttons, over which are designating words. To his left are a series of electrical bells, also provided with designating words. Now, a farmer drives up with a load of wheat, and the scale bell tinkles the fact to the head miller, who, with his right hand, presses the button which opens the door to the scale hopper. The farmer dumps his wheat therein, and its weight is at once shown up to the head miller by figures electrically displayed. While this is being done another bell rings, and the words "Feed Out," or "Spout Choked," or other specifying phases are shown him, and he, by simply pressing the proper button, remedies all difficulties, and continues smoking. Pretty nice outlook for the dusties, don't you think so?

THE NEUMAYER TELEPHONE RECEIVER.—In the receiver of M. A. Neumayer the magnet is formed by five small bars of the best quality of English steel. In order to obtain an increase of mobility in the magnetism, the inventor employs a bundle of very fine iron wires in connection with the pole nearest to the membrane. Towards its centre this bundle is soldered to a brass socket, a small part of which makes good contact with the magnetised rods, while the other part supports the coil, which has a resistance of about 100 ohms. To avoid the variations of distance, which are in effect variations of temperature, between the pole and the diaphragm he has a plate of brass soldered to the centre of the bundle of wires, to screw upon the box carrying the vibrating plate; this box is of brass, and the diaphragm, of a thickness of three millimetres, rests upon a a breadth of two millimetres upon the upper part of the box. The magnetised bars are maintained in a brass ring, which has a corresponding number of grooves.

PROPOSED CABLE BETWEEN WESTERN AUSTRALIA AND THE MAURITIUS AND NATAL.—The Mauritius correspondent of the *Natal Mercury* says:—"The question of laying a cable from Western Australia to Mauritius and Natal has just been referred to a full committee of the Council of the Government. Some fears were entertained by Sir James Anderson that the weather is so bad between the Australian coast and Cape, *viâ* Mauritius, as to render it next to impossible to effect repairs in the cable. Before submitting the papers to Council, they were referred to an able meteorologist, Dr. C. Meldrum, F.R.S., for his opinion on the question raised as to the meteorological and physical difficulties that are alleged to exist in the way of repairing and maintaining the cable in the sea between Australia and Mauritius. Dr. Meldrum has given it as his decided opinion, based on close observations, extending over thirty years, that, as regards storms, a telegraphic route to Swan River or North-west Cape to Natal, *viâ* Mauritius, would be safer than the telegraphic route between Ireland and Newfoundland."

AN ELECTRIC RAILWAY IN MARYLAND.—We notice in the *Maryland Journal* that the Union Passenger Railway Company, of Baltimore, has commenced the building of a branch connection to Mount Vernon, Hampden, and Woodbury, in which electricity will figure as the motive power. The electric conductor will be a third rail laid in the centre of the regular rails. The cars will be drawn by motors with electric machinery. The contact between the electric rail and the motor is by a wheel, which runs over the rail. A motor, independent of the cars, is being made to try the experiment, and if it is successful, it is likely that the future motors will be part of the cars, so that one man may run the motor and act as collector of fares. It is claimed for the new system that it will be cheaper than horses; that there will be no noise, no smoke, and no cinders, and that it will run from eight to ten miles an hour. The pressing of a finger against a button is all that is required to manage the motors. The length of the new road is two miles and a quarter, and it is expected to be ready for use about the middle of this month.

DOMESTIC ELECTRIC LIGHTING.—The seat of J. Wilson, Esq., Daramoun, County Westmeath, Ireland, has recently been lighted by means of the electric light, the motive power being derived from a small waterfall situated about half a-mile distant. The lighting is effected with incandescent lamps working off Frankland accumulators, to which the current is supplied during the day by a dynamo driven by a turbine. At a ball given recently the ball room was brilliantly lighted by the electric light. No fittings whatever were employed, the incandescent lamps (20 candle-power) being supported upon the shrubs, trees, and floral decorations of the room. A very pretty effect was introduced by placing some of the lamps in large bowls containing tinted water; while another and more quaint effect was given by a number of looking glasses in moss and ivy, into which lamps of 10 candle-power were placed in such a manner that the lamps were invisible, the arrangement resembling small ponds of crystal. The work has been carried out jointly by Mr. W. E. Wilson and Messrs. A. R. Sennett and Co., by whom the accumulators, &c., were supplied.

CABLE COMMUNICATION WITH ASIA.—A correspondent of the *Colonies and India* writes as follows:—"In view of the present agitation in Hong Kong for independent and more direct communication, would not this be a favourable opportunity to advocate a trans-Pacific cable from Hong Kong to Vancouver, which will shortly be in direct communication with England? It appears to me that both commercial and military ends make it desirable. Canadian merchants will in future seek a large direct trade with the Orientals, and will require the most prompt information of their markets. At present (unless I am misinformed), they must cable Eastern Asia *viâ* Europe. As in railway traffic, cable tariffs have relationship to the length of line traversed, and delivery by a direct route is likely to be more efficient and stable than by one of a number of sections, sometimes passing through foreign territory. From a military point of view, the arguments applying to the Canadian Pacific Railway, as a valuable alternative in time of need, apply with equal force to the cable communication. Anyone who is not familiar with the relative distances by the eastern and western routes to China and Japan should refer to a map of the world to see how obvious is the advantage in the latter."

THE INDO-EUROPEAN TELEGRAPH COMPANY.—This Company's report states that the revenue from all sources for 1884 amounted to £98,103. The expenses were :—On commercial and general account, £24,639 ; on maintenance account, £28,684, including £151 paid to the Russian Government ; total, £53,323. Deducting the above expenses, taking credit for balance brought over from 1883, and debiting income tax, there remains the sum of £43,571. From this amount, £10,625 paid for interim dividend, and £5,000 paid to Messrs. Siemens in final liquidation of their agreement of 16th July, 1868, have to be deducted, leaving a balance of £27,953 available. The Directors propose the declaration of a dividend for the last six months of 17s. 6d. per share, making with the interim dividend already paid 6 per cent. for the year, and a bonus of 10s. per share, making in all 8 per cent. for the year. The balance of £4,578 will be carried forward. The amount received on account of the Persian debt, £1,986, constitutes the first payment on account of the item of £21,846 standing to suspense account, which will be gradually liquidated by similar annual deductions from the royalties payable by the Company to Persia.

THE ELECTRIC LIGHTING OF THE LIBRAIRIE HACHETTE IN PARIS.—The large workshops of the Librairie Hachette in the Rue Stanislas in Paris are now completely and effectively lighted by electricity. The installation comprises about 400 incandescent lamps variously distributed, the current being supplied by one dynamo of 200 lamps, and two of 60 lamps each. These are actuated by a motor of 50 horse-power. The principal dynamo, which is placed in a position about 20 metres distant from the others, is driven by a machine of 25 horse-power specially devoted to this installation, and which, in case of accident, can be utilised to drive either or all of the three dynamos. The boiler of this machine is always under pressure during the day for various purposes connected with the Librairie. When it is necessary to light up, the machine can be put in motion in a few minutes. The lighting can be effected either with one dynamo or with the three coupled in multiple arc. The 60-lamp dynamos are by Edison, of the pattern shown in the Electrical Exhibition of 1881, while that of 200 lamps is a new model, giving a current of 150 amperes, with a tension of 120 volts at a speed of 1,300 revolutions. The internal resistance of the coil is 0·023.

THE ROYAL VISIT TO IRELAND.—The *Standard* says :—"Rarely has a nobler entertainment been offered to guests of any rank than that which was given to the Prince and Princess of Wales on Monday evening by the Citizens' Reception Committee. The committee made all their arrangements on the most colossal scale, and such a ball has certainly never been seen before in the Irish capital. The vast halls of the Royal Dublin Society, in which the agricultural shows are held, were placed at the disposal of the promoters, and they succeeded in effecting a most astonishing transformation in the aspect of the interior of the building. Instead of the bare whitewashed walls and uncovered floor, which are the familiar characteristics of the place, the guests were surprised to find a beautifully decorated ball room. The supper room presented a scarcely less ornate appearance. All the tables, that set apart for the Royal guests especially, glittered with glass and silver, which sparkled in the soft light shed by the hundreds of electric lights with which the building had been fitted up for the occasion. The space in front of the Royal table was ornamented in the most profuse manner with flowers and plants and beds of moss, and no feature in the scheme of decoration presented a more beautiful appearance than this."

A NEW SYSTEM OF TIME.—From a paper read by Prof. Loudon before a meeting of the members of the Canadian Institute, Toronto, Canada, we extract the following :—The present day of 24 hours would be divided into ten divisions, so that each hour, if we might so call it, on the new system would correspond to 2 hours 24 minutes. This hour would be again divided into 100 divisions, called minutes if necessary, each minute on the new system thus corresponding to 1·44 minute, a good fractional unit. Again, this new minute division could be subdivided for accurate measurements into 100 divisions, called seconds. The advantages arising from such a system would be : 1. The abolition of the so-called a.m. and p.m. nuisance—what has already been accomplished by the 24 hour system. 2. All the advantages to be derived from the adoption of any system based on our scale of 10—namely, the inconveniences arising from the continual use of vulgar fractions and the use of symbols for each unit in the ordinary affairs of life. 3. The fact that the time in hours and minutes (which for all practical purposes is sufficient) is indicated immediately by the clock. This is the most important advantage, because in the present system we have always to multiply by five before we know the time—thus 1 means five minutes past, 2 means ten, 11 means fifty-five past, or five to, and so on ; and this would really overcome, said the professor, the great difficulty experienced by most children in learning to tell the time.

THE SHEFFIELD TELEPHONE EXCHANGE.—Since October last year extraordinary activity has existed in this very successful private undertaking. At that time it was thought desirable to rearrange the rates of subscription, and the result has been exceedingly gratifying to the management. More than 100 subscribers have been attached to the Exchange during the past six months, and orders for attachment are still far ahead of the construction staff. A great improvement has also been manifested in the private wire branch of the system ; that is, in wires that do not pass through the Exchange. The Exchange and private wires now extend in various directions from ten to twelve miles around Sheffield. Over 13,000 messages per week are passed through the Exchange ; 11 call offices have been opened in the town and district, and five more call offices are about to be opened. The public are admitted to these call offices at a charge of 2d. and 3d. per conversation. The permission of every subscriber has been obtained to allow the free use of his instrument by the public in case of an alarm of fire or accident, and as this fact has been made well known a most complete and comprehensive fire alarm system is thus established. The business has now grown to proportions altogether too unwieldy for private enterprise ; and, as greater and more important developments are immediately contemplated, it has been decided to place the future of the Sheffield Telephone Exchange in the hands of a limited company.

THE TRANSMISSION OF POWER IN NEW YORK CITY.—A correspondent of the New York *Electrical World* writes as follows :—"The Electric Power Company, an organisation composed of some of the most prominent business men of New York City, have commenced active work, having purchased the rights of the Daft Electric Light Company for the counties of New York and Westchester. The Company take as a nucleus the plant put in by the Daft Company on Spruce-street, New York City, in January, 1884. This plant consisted of a six horse-power dynamo located in Buxton, Heims & Co.'s steam power plant, 13, Spruce-street. At first wires ran only to Nos. 32 and 33, Spruce-street. The motor there ran their elevator, its maximum load being 2,000 pounds. In March the plant was increased, another motor similar to the former being put in another leather house, next door to the

Digitized by Google

above. This motor did similar work and ran in parallel with the first. These motors now show but trifling wear. The same armatures, the same commutators, the same everything, are to-day in use. The commutators of the motors have not yet been turned, the wear after a year's run not yet warranting it, although tons have been hoisted daily. Their run has been extraordinary. They demonstrate beyond all question their eminently practical qualifications for such work. Two weeks ago the Electric Power Company substituted one of the Daft Company's largest dynamos in place of the smaller one at 13, Spruce-street. It is their intention now to add as rapidly as possible to the plant. A large order has been handed the Daft Company for motors, aggregating some 30 horse-power. The business of the new company is in able hands, and we feel sure that a revolution of motive power in New York City has started. Economy of room, economy of money, are the desiderata. They will be realised."

THE TELEPHONE IN EUROPE.—Some interesting statistics of the telephone lines in Europe have lately been given by *L'Ingenieur*:—In Italy, at the end of 1884, ten towns possessed telephone lines as against the same number in the previous year, but the number of subscribers showed an increase of 30 per cent. Eleven towns in France had telephonic communication during 1883 and 1884, the number of subscribers increasing 15 per cent. Belgium, at the close of 1884, had five towns connected up; and an increase of 19 per cent. in the number of subscribers. In England, London had a similar increase of 25 per cent.; and Liverpool, Manchester, Southport, and Blackburn together, 17 per cent. In Sweden, in 1882, only five towns had the telephone; in 1884 there were fifty-one towns; and the number of subscribers showed an increase equal to 398 per cent. in the two years. Switzerland had ten towns in 1883, and twenty-seven in 1884; increase, 112 per cent. Russia had, in 1883, six, and, in 1884, seven towns; increase of subscribers, 60 per cent. In Berlin there were 1,500 subscribers in June, 1884. Austria possessed, at the end of 1883, eight cities with telephone lines; and there were 708 subscribers at Vienna in December, 1884. In Norway, on June 30th, 1883, Christiana and Drammén, with 755 and 150 subscribers respectively, were the only towns having such a system. In Denmark, Copenhagen had 516 subscribers in June, 1883. Portugal, at the end of 1883, had Lisbon, with 343 subscribers, and Oporto, with 183 subscribers. The following additional information has also appeared from time to time in our columns:—Denmark, Copenhagen, at the end of 1884 had 1,105 subscribers. England; Dundee, February, 1885, 400 subscribers. New Zealand; at the close of 1884, there were about 1,100 subscribers in the colony, and 100 country stations were open where the telephone is used instead of the Morse instrument. In Holland, in March, 1885, the Nederlandsche Bell Telephone Company alone had 2,400 names on their list. France; 68 call offices are now open in Paris. Germany; the telephone was introduced into this country in 1880; there are now 58 country exchanges, possessing a network of wires extending over a distance of 10,100 miles. San Domingo; an exchange was in course of erection in Puerto Plata last month. Spain; there were last month 80 places connected with the central station in Madrid. Phillipine Islands, at Jolo, between the outlying forts and the residence of the military governor. Mozambique Island, between the fort and the residency, put in in 1880.

UNDERGROUND WIRES AND CHOLERA.—Our American contemporary the *Sanitary Engineer* says:—"The New York City Board of Health has passed resolutions to the effect that the excavations necessary to place the telegraph wires under ground in one season, as required by law, would prove highly detrimental to the health of the city, and that street excavations should be avoided as far as possible during the coming summer, owing to the special danger of an invasion of cholera. We believe that this action of the Board of Health is unnecessary and unwise, but it is to some extent excusable on the ground of the communication addressed to the Board by certain prominent physicians of the city, advising against excavations in the streets for fear of cholera. We do not think that the physicians thus advising have sufficiently considered all sides of the complicated question which they have thus decided, and fear that they have been unduly influenced by the urgent appeals which have been made to them in the name of humanity, but really in the interests of those who wish to postpone the burying of the wires, and have given too little consideration to the danger and nuisance of leaving things as they are. From the present condition of the telegraph wires in this city it would be a practical impossibility to remove them entirely from above the streets between this and the first of November, but the idea that the work can be postponed and resumed after the first of November, to be stopped again the first of May, 1886, is absurd, since in all well-regulated municipal work in northern latitudes there is a provision in contractors' specifications that excavations shall not be made or trenches filled between the first of November and the middle of April. The Board of Health has evidently done too much for the telegraph companies, who would not care to make their excavations by blasting, nor would any engineer care to have a trench filled with chunks of frozen dirt, nor would any one enjoy a drive over a pavement laid on such a foundation. Except in certain down-town portions of the city, where several lines of gas-pipes and the steam-heating pipes with their several branches into various buildings will be met with, the trenches required for placing wires underground will be comparatively narrow and shallow, and need not be open for any length of time. The work should be proceeded with as soon as the frost is out of the ground, and we do not believe that the danger to the public health is worth considering in comparison with the increased comfort and security which the public would gain from having the work done."—Commenting upon this question the *Pall Mall Gazette* says:—"The organised effort to burke the compulsory order of Congress that all telegraph and telephone overhead wires in New York shall be placed underground before the 1st of November next has advanced another step. Having won over a certain class of physicians to professionally declare that the necessary excavations would lay the city open to the inroads of cholera, the affected interests have now got the New York City Board of Health to back up the physicians with a resolution declaring that the excavations necessary would prove highly detrimental to health, and should be avoided as far as possible during the coming summer, owing to the special danger of an invasion of cholera. Of course, once postponed till November, a further postponement over the winter would be easy, for it is a common provision in contractors' specifications in America that excavations shall not be made or trenches filled between the 1st of November and the middle of April. Then in the following summer yellow fever at Panama or Vera Cruz, or leprosy at Honolulu, or some other epidemic, could take the place of the cholera excuse, and the wires might swing for ever overhead, with the simple addition of the doctors' fees to the working expenses. But will Congress allow itself to be so playfully trifled with? We think not. Anyhow, the crisis will certainly become acute between this and the 1st of November next."

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 431.)

Work done by Impressed Forces during Transient States.

When we charge a condenser by means of a voltaic battery a transient current is set up in the circuit, which is quickly stopped by the elastic reaction of the electric displacement in the dielectric. There is then a certain amount of electrostatic energy set up in the condenser, say U, and, during the charge, a certain amount of heat was generated in the conductor. That its value is also U (expressed as energy, to save the perfectly useless introduction of the mechanical equivalent of heat), may be seen at once on remembering that when we discharge the condenser through the same resistance (without impressed force), the current passes through the same series of values at corresponding times as during the charge, and must therefore generate the same heat, which, being now derived from the potential energy of the condenser, must amount to U. And we further see that whether the discharge circuit has or has not the same resistance as the charge circuit, the heat during the charge and discharge are equal, namely U. Thus, in charging the condenser, the battery does 2U of work, half of which is accounted for by the Joule heat during the charge, and the other half by the energy of displacement in the condenser.

This property is wholly irrespective of the manner in which the charge takes place, if no other work be finally done than in heating and in setting up electrostatic energy. Thus a coil may be inserted in the circuit, which may materially alter the manner of the charge, and render it oscillatory; still, the heat will amount to U as before. And if we put another coil near the first, so that there is a current during the charge in it as well as in the main circuit, the heat will still be exactly U, provided we include the heat in the secondary coil as well.

Similarly in charging a submarine cable, the distant end being insulated or only connected to earth inductively through condensers, so that the final state is one of no current (practically), the total heat during the charge exactly equals in value that of the electrostatic energy set up in the dielectric of the cable, condensers, etc., when we count the Joule heat in the conductor, sheath, and wherever else there may be conduction current during the charge.

The general law, of which the above are examples, is as follows:—If, in any arrangement of matter, conducting (metallically), or dielectric, or both, originally uncharged and free from current, we cause any steady impressed forces to suddenly commence to act, and we keep them on, whose distribution is such that the final state is one of no current, the Joule heat generated in the conducting parts during the transient state will exactly equal in amount the value of the final electrostatic energy set up. The impressed forces may be either in the dielectric or the conducting matter. If in the former, it does not matter how they are distributed, for the final state will be one of no current; but if in conducting matter the distribution of impressed force ceases to be permissibly arbitrary. In a linear conducting circuit, for example, their sum must be zero round the circuit. If partly conductive, partly inductive, this ceases to be necessary, but the impressed forces must act equally over the whole cross-section of the conductor, otherwise the final state will not be one of no current.

Suppose, however, other things being the same, the distribution of impressed force is left perfectly arbitrary in the conductors as well as in the dielectrics, with the result that the final state is a certain distribution of steady electric current in conductors, of electrostatic energy in dielectrics, and of magnetic energy in both, all to be definitely known from the given data, the distribution of impressed forces, of conductivity, capacity, and permeability. This we may conveniently divide into three cases; first, the final magnetic energy negligible in comparison with the electrostatic; next, the electrostatic energy negligible in comparison with the magnetic; and last, the real case, both being counted.

In the first case we have a transient state of induction, during which the actual electric force anywhere is that due to the impressed force on the spot and the changing electrostatic force (though "static" is rather misapplied) with electric current, both in conductors and dielectrics, leading to a final state in which the current is confined to conductors. Now, if there had been no electrostatic capacity, the final state of current would have been set up instantaneously, the activity of the impressed forces would be $\Sigma e C_0$, a being the impressed force anywhere and C_0 the current, the summation to include all places where e exists. This activity would have existed from the first moment, so that at the time t after the putting on of the impressed forces, the whole work done by them would have been $t\Sigma e C_0$, wholly accounted for in Joule heating. In reality, when there is electrostatic energy set up as well, the whole work done by the impressed forces up to the time t, to include the transient state, exceeds the amount $t\Sigma e C_0$, which would have been done had there been no electrostatic energy to set up, by the amount 2U, if U is the final energy of electric displacement. Besides doing an additional amount of work U in setting up the energy of electric displacement, the battery does an equal additional amount, which is accounted for as extra Joule heating.

Thus, in charging a shunted condenser, or a cable whose further end is to earth (if we do not count the electromagnetic induction), U being the value of the final electrostatic energy, the battery will do 2U more work than if the electrostatic capacity were *nil*, half in extra heating, half in setting up the electrostatic energy.

In the second case we have a great difference. Here electromagnetic induction is predominant. The law is now (other things being the same) that the impressed forces do 2T *less* work than they would have done had there been no magnetic energy to set up, T being the value of the final magnetic energy. In the electrostatic case the work done was $t\Sigma e C_0 + 2U$; it is now $t\Sigma e C_0 - 2T$, up to any time t including the transient state. Hence the Joule heat (instead of being U more), is now 3T less than if no magnetic work had been done.

In both cases, U and T, the electric and magnetic energy, are recoverable, appearing as Joule heat in the conductors when the impressed forces are removed; but the doing of electrostatic work makes the impressed forces work faster, and of magnetic work slower. The one is potential energy, the other kinetic. The one is connected with elasticity, the other with inertia.

Lastly, coming to what is really always the case, both electric and magnetic energy set up. During the transient state the coexistence of the two inductions causes a singularly complex state of affairs, by no means the mere resultant of the two taken separately. Yet the law, which we might guess from the preceding, is that the additional work done by the impressed forces above the amount $t\Sigma e C_0$, that they would have done had there been no electric and magnetic energy to set up, amounts to $2U - 2T$, being 2U more on account of the electric energy U and 2T less on account of the magnetic energy T; whilst the Joule heat is increased by $U - 3T$.

This includes, of course, all the preceding special cases. Thus, in the case of charging a condenser, the final current $C_0 = 0$, and $T = 0$. The additional work $2(U - T)$ may of course be either positive or negative, according to the values of U and T.

The following proof covers the whole, the impressed forces being arbitrarily distributed, and the matter having any conductivity, capacity, and permeability. Also colotropy in these three respects is included.

Let e be the steady impressed force at any place, put on at the time $t = 0$, and kept on. Let E, H, Γ, G, be the electric force, magnetic force, electric current and magnetic current, at the time t after the commencement, and E_0, H_0, Γ_0, their final values, G_0 being zero.

The activity of e is $e\Gamma$ at any moment, and the total activity is $\Sigma e\Gamma$ through all space, or wherever e exists. Let F be any "polar" electric force, then

$$\Sigma F\Gamma = 0, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (55)$$

because F has no curl, and Γ no divergence; a well known theorem that is made visibly true by considering that the tubes of Γ are closed, whilst the line integral of F round any closed curve is zero.

Digitized by Google

Now, in the transient state, the equation of induction is

$$\text{curl}\,(e-\mathrm{E}) = 4\pi\mathrm{G}\,; \quad \ldots\ldots \quad (56)$$

which becomes, in the final state,

$$\text{curl}\,(e-\mathrm{E}_0) = 0\,;$$

whence

$$\mathrm{E}_0 = e + \mathrm{F}_0, \quad \ldots\ldots\ldots \quad (57)$$

where F_0 is polar, or $\mathrm{F}_0 = -\nabla\mathrm{P}$; P being a scalar potential, the electric potential. Choose then $\mathrm{F} = \mathrm{F}_0$; then, by (55) and (57)

$$\Sigma e\Gamma = \Sigma e\Gamma + \Sigma\mathrm{F}_0\Gamma = \Sigma\mathrm{E}_0\Gamma\,; \quad \ldots \quad (58)$$

or the activity is the same on putting the final real electric force for the impressed force.

Now

$$\Gamma = \mathrm{C} + \dot{\mathrm{D}}, \quad \ldots\ldots\ldots \quad (59)$$

C being the conduction and $\dot{\mathrm{D}}$ the displacement current, D being the displacement (elastic). Therefore, by (58) and (59),

$$\begin{aligned}\Sigma e\Gamma &= \Sigma\mathrm{E}_0\mathrm{C} + \Sigma\mathrm{E}_0\dot{\mathrm{D}},\\ &= \Sigma\mathrm{E}_0 k\mathrm{E} + \Sigma\mathrm{E}_0\dot{\mathrm{D}}, \quad \text{because } \mathrm{C} = k\mathrm{E}\,;\\ &= \Sigma\mathrm{C}_0\mathrm{E} - \Sigma\mathrm{E}_0\dot{\mathrm{D}}, \quad \ldots\ldots \quad (60)\end{aligned}$$

k being the conductivity, and $\mathrm{C}_0 = k\mathrm{E}_0$ the final conduction current, $= \Gamma_0$.

But

$$\text{curl}\,\mathrm{H}_0 = 4\pi\mathrm{C}_0\,; \quad \ldots\ldots\ldots \quad (61)$$

therefore,

$$\Sigma\mathrm{C}_0\mathrm{E} = \Sigma\,\frac{\mathrm{C}_0}{\text{curl}}\,\text{curl}\,\mathrm{E} = \Sigma\,\mathrm{H}_0\,(\text{curl}\,e/4\pi - \mathrm{G})$$

by (61) and (56). Therefore

$$\begin{aligned}\Sigma\mathrm{C}_0\mathrm{E} &= \Sigma e\,\text{curl}\,\mathrm{H}_0/4\pi - \Sigma\mathrm{H}_0\mathrm{G}\\ &= \Sigma e\mathrm{C}_0 - \Sigma\mathrm{H}_0\mathrm{G}.\end{aligned}$$

Putting this in (60), we get

$$\Sigma e\Gamma = \Sigma e\mathrm{C}_0 + \Sigma\mathrm{E}_0\dot{\mathrm{D}} - \Sigma\mathrm{H}_0\mathrm{G} \quad \ldots\ldots \quad (62)$$

This is true at every moment. Now integrate (62) to the time, from 0 to t, to include the transient state (t must mathematically be infinity), and we get

$$\Sigma e\int\Gamma dt = t\Sigma e\mathrm{C}_0 + \Sigma\mathrm{E}_0\mathrm{D}_0 - \Sigma\mathrm{H}_0\mathrm{B}_0/4\pi \quad \ldots \quad (63)$$

D_0 being the final displacement, B_0 the final magnetic induction. But

$$\mathrm{U} = \tfrac{1}{2}\Sigma\mathrm{E}_0\mathrm{D}_0\,; \quad \mathrm{T} = \tfrac{1}{2}\Sigma\mathrm{H}_0\mathrm{B}_0/4\pi$$

are the values of the final electric and magnetic energies. So (63) becomes

$$\Sigma e\int\Gamma dt = t\Sigma e\mathrm{C}_0 + 2\mathrm{U} - 2\mathrm{T} \quad \ldots\ldots \quad (64)$$

which is the required result, showing that the work done by the impressed forces is increased by 2U on account of the electric energy, and reduced by 2T on account of the magnetic energy, the Joule heat being increased by U − 3T.

I have written out the above rather fully. Without the explanations, it goes simply thus,

$$\begin{aligned}\Sigma e\Gamma &= \Sigma\,(e+\mathrm{F}_0)\,\Gamma = \Sigma\mathrm{E}_0\Gamma = \Sigma\mathrm{E}_0\mathrm{C} + \Sigma\mathrm{E}_0\dot{\mathrm{D}}\\ &= \Sigma\mathrm{C}_0\mathrm{E} + \Sigma\mathrm{E}_0\dot{\mathrm{D}} = \Sigma\mathrm{H}_0\,(\text{curl}\,e/4\pi - \mathrm{G}) + \Sigma\mathrm{E}_0\dot{\mathrm{D}}\\ &= \Sigma e\mathrm{C}_0 + \Sigma\mathrm{E}_0\dot{\mathrm{D}} - \Sigma\mathrm{H}_0\mathrm{G},\end{aligned}$$

whose time integral is

$$\Sigma e\int\Gamma dt = t\Sigma e\mathrm{C}_0 + 2\mathrm{U} - 2\mathrm{T}.$$

This shows how much may be put in a small compass.

We should remark that it is Γ the true current that is divergenceless, in general, not C or $\dot{\mathrm{D}}$ separately, except in the final state, when the current is wholly conductive. Also, that we twice make use of the theorem

$$\Sigma\mathrm{A}\,\text{curl}\,\mathrm{B} = \Sigma\mathrm{B}\,\text{curl}\,\mathrm{A} \quad \ldots\ldots \quad (65)$$

through all space, A and B being any vector functions; of this (55) above is a special case. Giving proofs of all the potential properties made use of is out of the question. I entered fully into these matters in former articles in this journal. It is customary in mathematical investigations in electromagnetism to virtually prove this and similar theorems over and over again in the course of working out results, instead of merely quoting them; like proving a proposition in "Euclid" *ab initio*, from the axioms and definitions. It would, however, be very desirable to have special names for the various useful vector theorems connected with the ∇ operator. This is sometimes done by quoting a man's name, and leads to confusion, if two theorems are called, for instance, Laplace's theorem. I think the three fundamental theorems of Slope, Version, and Divergence would be recognisable by these names by anyone acquainted with the theorems, though not previously with these names for them. From them follow a number of others of the greatest utility, of which (65) is an example.

(TO BE CONTINUED.)

A SELENO-DIFFERENTIAL RECORDER.

It is a well-known fact that the weak currents necessarily used in submarine telegraphy, where the points connected by cable are very distant from each other, are capable of working only a limited number of telegraphic instruments. For practical working these instruments consist almost solely of Thomson's reflecting galvanometer and syphon recorder. These, it is almost superfluous to say, are sufficiently sensitive for any purpose, but they possess in themselves certain disadvantages not easily overcome. The reflecting galvanometer, or, as it is almost universally called, the "mirror," is a visual, and not a recording, instrument, and some considerable skill is in many cases required in its manipulation. The syphon recorder, the most perfect instrument we have yet seen for the purposes of long-distance telegraphy, requires to be maintained by powerful and expensive batteries, which feed the mouse mill and the electro-magnets. This expense in regard to the electro-magnets can, as is well known, be dispensed with by employing permanent magnets, but the cost of the energy required to actuate the mouse mill still forms a somewhat large item. Several attempts have been made from time to time by various persons to record the visual signals received on the mirror instrument, in order to obtain a greater degree of accuracy, with a view to increase its efficiency. These attempts have, practically speaking, all resulted in failure.

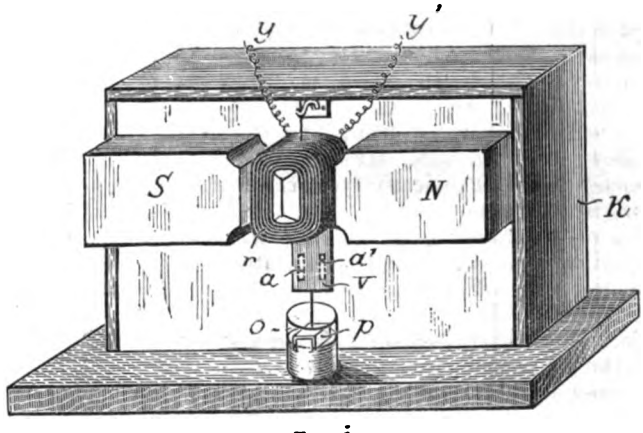

FIG. 1.

Not long ago we had occasion to experiment in this direction, and obtained some good results in regard to greater accuracy by using two pieces of selenium of unequal dimensions in the circuits of two telephones, which gave out sounds upon the resistance of each piece of selenium being altered under the action of the ray of light reflected upon them when the instrument was in operation. The apparatus we are about to describe, which is the invention of Baron Von Taund-Szyll, of Graz, is based in some measure upon the same principle, but possesses the additional advantage of recording the signals as they are received. As regards its practical value we are unable to speak, having no data before us, but if it realises the expectations of its inventor it cannot fail to attract a large share of approbation. The apparatus consists of two main parts, the receiver and releaser, and the relay or simultaneous writing apparatus, constituting the differential recorder.

Fig. 1 is a perspective vertical sectional view of the receiver,

Digitized by Google

Fig 2 a plan section of the apparatus, and Figs. 3 and 4 are detailed views. The receiver consists of a tightly-closed box, K, Figs. 1 and 2, containing in an interior compartment a powerful source of light, the rays from which can pass out through two small narrow slits *a* and *a'*, shown also to a larger scale in side view Fig. 3 and plan section Fig. 4. As the light source, an intense glow lamp, *g*, may advantageously be applied, is placed close behind the partitions shown in Fig. 2.

The releaser consists of a small spool frame, *r*, similar to Sir William Thomson's syphon recorder, which is suspended by a silk fibre, and is movable within a very powerful magnetic field N S. The small frame *r* has (as shown in all the figures) a lower prolongation or shutter, *v*, which is of triangular section, and which hangs so in front of the partition of the box K, as to cover exactly the slits *a a'*, and thus when the frame *r* is at rest, prevents the light rays from the glow lamp *g* from passing out through the slits *a a'*. But when the cable current passes through the wires *y y'* into the coils on the spool of the frame *r*, then the frame *r* will be swung lightly to the left or right, according to the polarity of the current, and will thus be brought nearer to one of the magnet poles. As the lower prolongation or shutter *v* partakes of this motion it will open for the slit *a* or *a'*, and let the light rays out of the box K. The light is thus released.

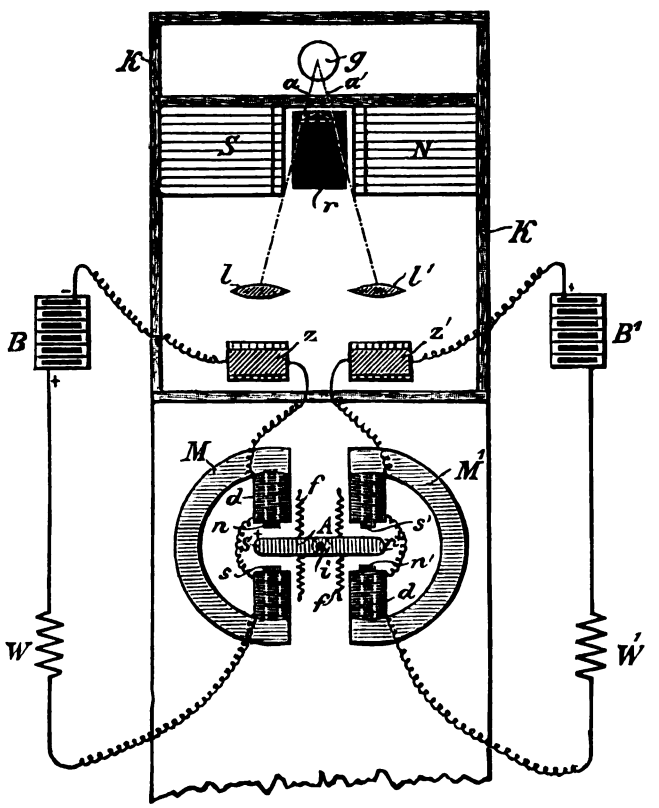

Fig. 2.

In order to regulate the frame *r*, that it does not come into a pendulous motion and so that it may return from a movement into a position of rest, and without going off into an opposite direction, a small plate, *p*, is suspended from the aforesaid shutter *v*, and dips into a small glass, *o*, which is filled with a mixture of glycerine and water to impede its motion.

The arrangement of the differential recorder is as follows:—Within the box K, but in front of the slits *a a'*, in the aforesaid back partition, two powerful convex or collecting lenses, *l* and *l'*, are placed, the foci of which coincide with two selenium cells, *z* and *z'*, so that when one or other of the slits *a a'* is left open by the shutter *v*; the light rays will be concentrated by the collecting lens, and be thrown on the selenium cell on its opposite side. By the light falling on the selenium the resistance which it offers to an electric current flowing round it will, as is well known, be altered. Two polarised horseshoe magnets, M M', carrying soft iron polar cores with powerful coils, *d*, of the finest wire, are so arranged opposite each other that their like poles are crossways, opposite the south pole of one, and just opposite a north pole of the other. Between the poles of the magnets M M' a steel magnet or armature, A, is mounted, to turn on a vertical spindle, *i*, which armature, by means of four helical springs, *f*, is so adjusted that its sides are equidistant from the four pole pieces *n s* and *n' s'* of the two horseshoe magnets M M', whilst the current traverses their coils. It is now to be seen that a difference ever so small in the attraction of the four poles will draw the armature to one side or the other, and both the intensity of such movement and its exactness may be regulated by the helical springs *f*.

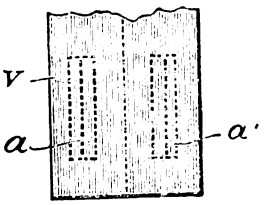

Fig. 3.

The coils of one magnet, M, are by a wire connected with the corresponding selenium cell, *z*, of a local battery, B, and an inserted variable resistance or coil, W; and the coils of the other magnet, M', similarly by a wire with the other selenium cell *z* of another local battery, B', with an inserted variable resistance, W'. The local batteries have several elements. The current from the first-named battery, B, goes to its selenium cell, *z*, then through the coils of the magnet M and the resistance coil W, back to the battery. In like manner a current from the other battery, B', goes to its selenium cell *z'*, then through the coils of the magnet M' and the resistance coil W', back to the battery B'. The two currents are consequently quite separate and distinct from each other.

If, now, the cable currents enter the small frame *r* in such a manner as to turn it towards the south pole, S, then the shutter *v* will open for the light rays to come out through the slit *a'* towards the north pole N, to be collected by the lens *l'* in front of the north pole, and thrown on to the corresponding selenium cell, *z'*. This is all the work which the cable current has to do.

In consequence of the light rays falling on the selenium cell *z'*, this latter will offer quite a different resistance to the current passing through it from the battery B' to that which it offered before the rays fell upon it.

Through this varying resistance, however, the current from the local battery B' is strengthened, but as it flows round the magnet M', the latter will be weakened, and hence, the other magnet M being the stronger, will draw the armature to it, and thus turn it. If a light ray passes out through the other

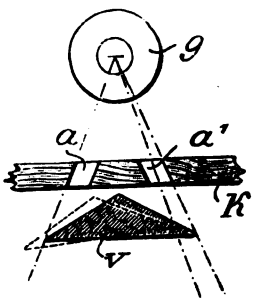

Fig. 4.

slit *a* (by the opposite movement of the small frame *r*) on to the other selenium cell, the same action will take place with regard to the other magnet M, and the armature be turned in the opposite direction. The peculiar arrangement of the magnet poles is in order that the poles should mutually support each other. The north pole *n* of one magnet, M, attracts the south pole *s* of the armature A, and is assisted by the repelling force of the south pole *s* of the same magnet. This assistance by the repelling action paralyses that of the

Digitized by Google

north pole n' of the other magnet, M', on the north pole n of the armature. As soon as the cable current ceases, and the small frame r returns to its position of rest, the slits a a' will again be covered by the shutter, and the selenium cell in question assumes its normal resistance, whereby the differential action of the polarised magnets M and M' again ceases, and the armature A returns to its position of rest, or rather the forces which brought it out of the state of rest come into equilibrium again. The inserted resistances W W' have for object to paralyse the resistance variation of the selenium *per se*—that is to say, to render possible a correction relatively thereto, and to equalise the resistances of the two current circuits (the inner and the outer).

The armature is so combined with a writing instrument that it directly or indirectly puts the writing lever into motion.

The whole first part of the apparatus, including the lenses and selenium cells—that is to say the sensitive parts, which may easily get out of order—may be kept air and dust tight under glass, and may be protected against unusual light variation by another covering of opaque material and only the differential recorder need stand in the work room.

SECONDARY GENERATORS.

The following letter has been addressed to Prof. Galileo Ferraris by Dr. J. Hopkinson :—

SIR : Owing to my ignorance of Italian I have been unable to read the copy of your paper, "Secondary Generators of Gaulard and Gibbs," which I received some weeks ago; but an abstracted translation of your paper which is appearing in our journals has made me aware that you have quite misunderstood what method of experiment I adopted in determining the co-efficient of efficiency of these instruments. That you should have thus misunderstood me is not altogether surprising, for I did not attempt to explain my method of experiment, as the purpose of my report was merely to inform the company which consulted me what the capability of their instruments really was. I did not, as I gather you assume, determine the mean difference of potential between two points of the circuit and the mean current in the circuit, and multiply these two together to obtain the work done, for I have for some years — in fact, since I first studied the theory of alternating currents — known that such a method would be erroneous. What I actually did was by a single observation of the electrometer to determine the mean value of the product at each instant of the current and the difference of potential. This is done by a very ingenious modification of the method of M. Joubert proposed by Profs. Ayrton and Perry some years ago. The method is as follows :—Let A B C be three points of a conductor in which an alternating current is passing; let the resistance between A and B be r, and let there be no self-induction or electrostatic capacity between A and B; it is desired to determine the work done by the current. Connect A and B to the two quadrants of the electrometer C to the needle, then if the quadrant electrometer be in perfect adjustment, the force tending to deflect the needle will be proportional to $(A - B)\left(C - \frac{A+B}{2}\right)$, A B C being the potentials at the corresponding points. Now, $C - \frac{A+B}{2}$ is the difference of potential between C and a point, D, midway between A and B, and $\frac{A-B}{r}$ is the current passing in the conductor, hence the force tending to deflect the needle at any instant is proportional to the work being done at that instant between the points D and C. Hence it follows that the deflection of the needle multiplied by the resistance r is a correct measure of the work done in unit time between D and C.

After this explanation I think you will agree with me that the method I adopted was correct, and that I have not made the error you not unnaturally supposed I had made.

Owing to the considerations which you point out, the efficiencies M. Uzel deduces from his experiments are all somewhat lower than those experiments really indicate. My own conclusions, viz. : an efficiency of 79·3 per cent. for the old type of instrument and 86·1 per cent. for the new type are the correct deductions from the observations which I made. My use of the electro-dynamometer in the case in which I used it for verification was also strictly correct, for the self-induction of the portion of the circuit in which I proposed to measure the work done was practically *nil*.

I send herewith a copy of my lecture before the Institution of Civil Engineers, and would ask you to refer to the remarks on p. 11, also a copy of a recent paper of mine on Alternate Currents, in which the subject of secondary generators is touched upon. From these I think you will see that I was hardly likely to make the fundamental error which you have attributed to me.

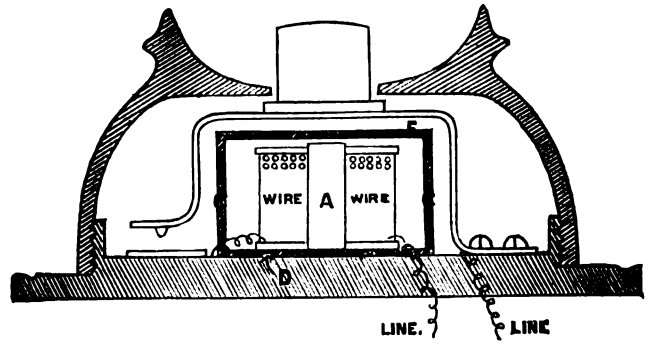
I am sending copies of this letter to the English journals in which abstracts of your paper have appeared.—Yours, &c.,

J. HOPKINSON.

THE MACKENZIE PATENT INDICATOR.

One of the usual complaints against electric bells is that no means exist of knowing whether the bell has rung when the push-button has been pressed.

The Mackenzie indicator, of which a sample and description has been forwarded to us by Messrs. Woodhouse and Rawson, seems to remedy this defect, and to be very simple, and, as far as we can judge merely upon inspection, of an efficient nature.



Its mode of action can be readily seen from the annexed sketch. A is a soft iron core, fixed to an iron base, D, and surrounded by a bobbin of wire, which forms part of the circuit upon which the appliance has to be used. An iron box, C, is placed over this electro-magnet, having the lid E close to the end of the core. Upon the current flowing round the bobbin the core A, and the lid E, being the respective poles of a continuous magnet, become magnetised with opposite polarities, and emit the sound; the make and break action of the bell, however, immediately comes into play, and the core and the lids losing their magnetism again emit a sound which continues to be given out as long as the current is passing.

This is the well-known "Page effect" made use of practically. The action being solely molecular no moving parts are needed, and it is therefore claimed that there is nothing to get out of repair; and being an audible instead of a visual indicator, its use is not restricted to any place where light is required. Its sound is capable of being increased to any desired amount. The apparatus can be adapted to any place where electric bells are used, and can also be made to take the place of a bell itself if required. Being exceedingly small, it can be fitted inside the push itself, the whole forming one complete instrument; or, if preferred, it can be made separately, and adapted to existing arrangements with but trifling cost.

Such an instrument might be applied to numerous other purposes than those set forth above, such for instance as (*a*) telephone circuits between exchange or subscribers; (*b*) between exchanges themselves, showing every time the call bell is rung that the bell is actually ringing, and that therefore the circuit is in proper order; (*c*) on railways in signal boxes this little indicator should be useful, as the pointsman would be certain that the signal transmitted by him to a distant signal box had been received.

IS THERE A TELEGRAPH TO MERV?

Last week we hinted at the desirability of one or more submarine cables to the East being in the hands of the naval and military authorities, the exact routes being known only to them. If it is objected that the secret could not be preserved for long, we would remark, first, that if it were preserved long enough to serve the purposes of a war its object would be accomplished. That such secrets can be kept is proved by what is happening now on the northern frontier of Persia and Afghanistan. For over nine months a telegraph line is known to have been in course of construction between Askabad and Merv; yet to this day its progress is uncertain, and even its existence is denied. Partly as illustrating the value of secret telegraphic communication, partly because of the diplomatic importance which attaches to the question whether there is or is not direct communication between St. Petersburg and the Russian military station at Merv, it may be interesting to bring together the evidence at our disposal bearing on this disputed point.

First, however, we should notice a fact, very much to the credit of the military system of Russia, that nobody in this country—at any rate, no Englishman—ventures to speak positively on the subject except at second-hand. Even Mr. Marvin has to trust to the testimony of a Russian newspaper, which to-morrow might announce that its previous information was erroneous. Our military Intelligence Department seems all in the dark, otherwise the Prime Minister would not speak with such uncertainty. The British representative at St. Petersburg is reported as believing there is no telegraph to Merv, and evidently he does not know how near to that place the telegraph line has been extended. The secret has been well kept; the uncertainty surrounding it has already done Russia an immense service, and may do more should the present negotiations be much further prolonged.

That a line of telegraph followed very closely upon the sudden acquisition of Merv is at least highly probable. The submission—or, as some people call it, betrayal—of the Mervis took place early in last year. An army was soon in possession of the place; and it is not the custom to leave a Russian advanced post out of touch with its base. In the June following we announced, on the authority of a telegram from St. Petersburg, that telegraphic communication was "in the course of construction between Merv and Askabad." Evidently the work had been begun—probably from the Askabad end. The railway went only to Kizil Arvat, we believe, but the telegraph had gone ahead of it as far as Askabad. From there to Merv direct the distance is 185 miles; by way of Sarakhs it is only 67 miles further; and, in spite of M. Lessar's suggestions to the contrary, the line could have been completed easily long before now.

On January 10th of the present year we published a statement that authority had been given for the construction of this particular line. Even if the line had only then been begun there has been plenty of reasons in the interval for constructing a military telegraph line over the distance, especially in the face of momentous events which were then impending, the advance of Russian troops far south of Merv, and within the "debateable" territory of Afghanistan, having taken place in the September previous. Besides this, we know that the railroad from the Caspian to Kizil Arvat was pushed on without "authority;" and we may surmise that the enterprising soldiers in charge of the Transcaspian business may not have waited for "authority" to erect a telegraph wire. But a sort of correction to the statement above referred to came almost immediately after it was made public. The *Standard's* correspondent at Teheran telegraphed that the Russians were *already* laying the line from Askabad to Merv, which seemed to imply that the line was in full course of construction, and had not been delayed for lack of authority. Indeed, we are left to fall back on the June telegram as not improbably a true account of the matter. The line was projected then; nothing had happened to delay its completion; many things were happening then and have happened since to expedite it.

On the 11th of the present month we reproduced a telegram from the *Daily Telegraph's* St. Peterburg correspondent stating that Sir Peter Lumsden's despatch *viâ* Meshed relating to the attack on Penj-deh had been delayed by the cutting of the Persian land wire; whereas "the Russian wire is continuous from St. Petersburg to Merv." The correspondent proved to be correct in one particular; none but political reasons of an amiable kind will persuade any practical mind that he was wrong in respect of the other statement. By a singular coincidence it took ten days or thereabouts for both despatches, travelling by different routes, to reach, the one St. Peterburg, the other London. If the correspondent just quoted was correct, it follows that the St. Petersburg telegram from Merv must have been—well, "delayed in transmission."

But that statement does not stand alone. Mr. Marvin's information, obtained from a Russian print, is conclusive. On the 2nd April the Tiflis *Kavkaz* stated the fact that the line from Askabad to Merv "is already constructed and in full working order." The capture of Pul-i-Khisti and Penj-deh took place on 30th March. Only 130 miles separate that locality from Merv, and still less from Sarakhs. And even if we take the most literal view of the *Kavkaz's* language, there can be no doubt that the line to Sarakhs was completed long before the 2nd April. This circumstance completely disposes of M. Lessar's explanations, to which the *Pall Mall Gazette* gives wide publicity. He doubts

Digitized by Google

the existence of the line, dwells upon the difficulty of its construction, the scarcity of poles, the transport of wire, of batteries, and so forth. But our announcement of January 10th that the line would take the Sarakhs route instead of going direct to Merv is confirmed by the *Kavkaz*; and as there is a road to Sarakhs from Ak Tèpè, close to the scene of the battle, much shorter than the road to Merv, urgent despatches would probably be forwarded by courier to Sarakhs; and this route would certainly be chosen if, as has been alleged, the telegraph is *not* completed to Merv.

According to the Russian agent in London it will take more than a fortnight for St. Petersburg to exchange communications with General Komaroff. Probably it will; but that it ought to take not nearly half the time is rendered plain by a glance at the map, and the evidence here adduced on the subject. Two telegrams from Meshed, dated 20th April, reached *The Times* and *Standard* offices for publication on the 21st; and Sarakhs is telegraphically as near to St. Petersburg as Meshed is to London. The *Standard's* telegram left Tirpul by courier on 16th. Tirpul is apparently the place where the British Commissioner and his escort have halted as fugitives, just on the eastern frontier of Persia. Four days, therefore, suffice for the camel ride; the distance between there and Meshed is certainly greater than from Pul-i-Khisti to Sarakhs, and little shorter than the road to Merv. Subsequent despatches have traversed the whole distance from Tirpul to London in less than four days.

One other point of some importance we must refer to before dismissing this painful subject. The *Pall Mall Gazette* has persistently asserted that the forward move of the Russians as far south as Zulfikar last September was a counter demonstration against, and justified by, the occupation of Penj-deh by Afghan soldiers last June. Its case indeed rests upon that. The true explanation is not far to seek; but in order to connect the two occurrences it has been repeated time after time that the Afghan occupation in June last was not known in St. Petersburg until the middle of September, where it arrived through the agency of "Dr. Regel at Tashkend." We leave political writers to deal with this astounding allegation as it deserves. All we have to say is that the telegraph brought news of the occupation to this country soon after the event; secondly, that it now only takes ten days (or probably less) to bring news which, it is alleged, took three months to travel last June; and, lastly, that whether or not the line to Sarakhs and Merv had made any progress nine months ago, the line was undoubtedly completed and working as far as Askabad. There were military posts from there to the Merv garrison, less than 200 miles distant; and Penj-deh is only two days' ride south of it. The telegraph would perform its part of the task in a day; yet we are asked to believe that the intelligence took three months in reaching St. Petersburg, and that it went by way of Tashkend. We can only hope that in time of need our military agents will keep the secret of their telegraph engineering operations as well as the Russians have kept theirs.

While the above was being written the *Pall Mall Gazette* announced that its inquiries had "elicited the fact" that the line does not now extend beyond Baba Durmaz, about 70 miles beyond Askabad. No authority is given for this statement, which flatly contradicts Russian testimony given before the question was in dispute. But granting the fact, can this 70 miles of wire make all the difference between three months in the summer of '84 and 10 days in the spring of '85? The reported interruption of the Caspian cable will now, however, render all further denials of the Merv wire quite unnecessary.

THE LATE MR. WILLIAM LADD, F.R.A.S.

We regret to announce the death of Mr. William Ladd, F.R.A.S., at his residence, Burnt Ash Hill, on Thursday, the 16th inst., at the age of 70. Mr. Ladd was well known in scientific and commercial circles for his efforts in the field of electrical research, for during the decade extending from 1860 to 1870 he took a very prominent part in introducing into practical utility the then comparatively obscure science of electricity, which is now deservedly receiving marked attention as the leading science of the day. Nor was his interest in this line confined merely to any particular branch of the science, for we find him at one time in correspondence with Prof. Reis, who may be said to have made the earliest efforts towards recording the sound of the human voice transmitted over long distances. A letter is still extant in which Prof. Reis explains to Mr. Ladd his views upon this question, and the partial success that attended his efforts. Mr. Ladd was well known as the inventor and constructor of some of the largest induction coils and electrical apparatus, manufactured under his supervision at his premises in Beak-street, Regent-street.

In 1867 Mr. Ladd brought forward a dynamo machine, which in many respects showed a marked improvement on the previous dynamos of Siemens, Varley, and Wilde, and whereby many of the then existing difficulties in the way of constructing dynamos for practical and commercial use were removed. Somewhat later, in the year 1878, Mr. Ladd was instrumental in introducing into this country the Wallace-Farmer system of electric lighting from America, where it had met with considerable success. The dynamos and arc lamps employed on this system underwent considerable improvement at Mr. Ladd's hands; and one of the earliest installations of electric lighting afforded to the public was made under Mr. Ladd's supervision on the above system at the Liverpool-street Terminus of the Great Eastern Railway.

Mr. Ladd was from the time of its formation a director of the Anglo-American Brush Electric Light Corporation (Limited), and also of the Electrical Power Storage Company, and he took an active interest in the administration of these companies until almost the day of his death.

CORRESPONDENCE.

INCANDESCENT LAMPS AND THEIR HOLDERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. Scott Snell's letter, in last week's *Electrician*, I think that he has mistaken the purport of my letter of March 14. Sir David Salomons had written in the previous number, complaining, as a consumer, of the frequent changes in the forms of lamps and their holders, a consumer having, according to Sir David's experience, to be continually putting his hand in his pocket, in obedience to some change made at the factory.

My object in the letter which, with your usual courtesy, you were kind enough to find room for, was to show that such frequent changes were by no means necessary, and incidentally to give the results of our own experience. I was not aware at the time to whom the honour of designing the holder was due. A sample was sent to us with a number of others by Mr. Lundberg, and after careful trial we adopted it for general use.

We have recently experienced some little difficulty with it over coaling screens, where the lamp receives a sudden jerk when the coal is tipped over on to the screen. We find that occasionally the loop jerks loose from the hook, a spark passes, often fusing the loop and the spiral hook or both, and the lamp, falling out, is broken. This is the first time we have met with any difficulty with this form of holder, and for this we are now trying Cox-Walker's new holder with the wire loop round the lamp.—Yours, &c., SYDNEY F. WALKER.

195, Severn-road, Cardiff, April 22, 1885.

ON THE SEAT OF THE ELECTROMOTIVE FORCES IN THE VOLTAIC CELL.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

(CONTINUED FROM PAGE 479.)

Observe that the contact has not developed any force; it has only, by sweeping away the oxygen from the point of contact, enabled previously existing forces to do work and produce their effect.

The air surrounding the metals in contact is in a state of slight dielectric strain, such as would be produced by two pieces of any one metal of similar size and position, charged so as to differ in potential from each other by a volt.

Zinc and copper plates in contact may therefore be regarded as the plates of a condenser, but they form a peculiar condenser, for they are not really at different potentials; the whole step of potential which throws the air into its state of dielectric strain is located on their bounding surfaces.

Let s and s' be the electrostatic capacity of the zinc and copper respectively; think of them as two independent spheres united by a fine wire; and let x be their common potential; then the zinc has, by the fact of contact, gone up $1{\cdot}8+x$, and the copper has gone down $x-{\cdot}8$; and, since the quantity of electricity which left the one went to the other, it follows that—

$$s(1{\cdot}8-x)=s'(x-{\cdot}8)$$

or

$$x=\frac{1{\cdot}8s+{\cdot}8s'}{s+s'}.$$

There is no necessary relation between s and s' in general, but in the ordinary form of the volta experiment the two plates are of equal size and shape; in which case $s=s'$, and $x=1{\cdot}3$ volt below the potential of the unconstrained air.

All this is wholly unlike a condenser investigation. To treat it as a condenser we must consider the air-surfaces close to the two metals as the plates of the condenser, and we can then speak of its electrostatic capacity S in the ordinary way, and say that it is in the present case charged with the E.M.F. of a volt.

The quantity of electricity on either plate of such a condenser is S $(1{\cdot}8-{\cdot}8)$ or S; hence

$$s(1{\cdot}8-x)=s'(x-{\cdot}8)=S(1{\cdot}8-{\cdot}8).$$

And the general relation between the three S's is like that of two Leyden jars in cascade, viz.,

$$S=\frac{ss'}{s+s'}$$

If the two pieces of metal are circular disks each of radius r, and at a distance z apart, the value of S is of course $\frac{r^2}{4z}$.

In Volta's form of the experiment, two plates are put near each other, connected for an instant, then removed from each other, and the potential of one of them observed. This measures $\frac{S(1{\cdot}8-{\cdot}8)}{s+x}$, where x is the capacity of the electrometer used.

In Pellat's form the charges acquired by contact are neutralised, and the oxygen atoms driven back to their normal distance, by an extraneous E.M.F. carefully adjusted until the plates, after separation, exhibit no charge. This measures $1{\cdot}8-{\cdot}8$ directly.

16. So far I have spoken as if I were sure that (granting the hypothesis) the potential of clean zinc is 1·8 volt below the air; but I am not really sure that this is anything better than an approximation. The fact that no actual combination occurs makes the matter perhaps a little indefinite. If an oxygen atom unites with a zinc atom, one has a right to say distinctly that q has stepped down v; but suppose they are only facing one another, and wishing to combine, are we justified then in asserting that the step v is ready for q to go down, and that it is the same v as before? It almost seems to depend on whether chemical attraction becomes greater as two atoms approach one another, or becomes less.

Suppose, first, it becomes greater, which is the natural hypothesis, then the v calculated from data obtained by permitting the combination to occur will be too large for the step of potential caused by the attraction of metal for oxygen over a standard distance. On the other hand, the differential force urging electricity across a junction of two metals, which is observed in the Volta effect, may be somewhat greater than simply the differences in their pull reckoned at standard distances, because the approach of atoms to the zinc will increase it on this side, and the recession of atoms from the copper will decrease it on that. Hence the Volta effect may perhaps be expected to agree better with calculation than the air/metal potential-difference does, if this latter could be experimentally observed, which it never yet has been.

Next, suppose that chemical attraction becomes less as atoms approach; the step of potential between a metal and air will now be greater than that calculated from chemical data; nevertheless, the Volta effect will be somewhat less than that due to the differences of such steps for two metals, and may thus possibly agree pretty well with calculation.

The agreement or non-agreement of Volta effects with calculation does not therefore quite establish the accuracy of our calculated metal-air contact-forces. But we have no right to assume that even Volta effects will agree with calculation particularly well so long as our data are so slender. They have no chance of accurately agreeing unless the metals used are pure and perfectly clean—a most difficult condition to attain for even a few seconds.

* Reprinted from the *Phil. Mag.* for April.

Before leaving this subject it may be well to point out that, whereas the *calculation* of a Volta effect depends on data obtained by allowing oxygen atoms to approach the metal so as completely and actually to combine, the *experimental determination* by Kohlrausch's and similar methods depends on letting the atoms approach somewhat nearer to one metal and recede somewhat further from another; while the *compensation form* of the experiment employed by Pellat and others depends upon forcing back and restoring the atoms to their original or standard positions. Now, if the views here just expressed have any sense or signification whatever in actual fact, it would be very natural to suppose that the numbers obtained in these three ways might be slightly different. But to specify the direction in which we should expect the differences, if any, to lie would require us to have made up our minds as to the probable variation of chemical attraction with distance. Assuming an inverse variation, the Pellat method should give the least, the Volta or Kohlrausch method the next, and the calculation method the greatest, value for the Volta effect.

But all these ideas complicate the matter somewhat, and they are quite possibly unnecessary. If it be considered that we have no data at present, it may be permitted to work on the simplest hypothesis, viz. that the step

TABLE A.—*Energy of Combination of Metals with Oxygen.*

* This number for sodic oxide agrees with Thomsen's value for the hydrated oxide, whereas for K, Ba, Sr, Ca the oxide is distinctly below the hydrate. By analogy, one would expect to have to subtract some 25,000 from the hydrated oxide $Na_2,O,aq.$, and this gives the 130,000 which I put down as a hypothetical number for Na_2,O.

Digitized by Google

v is independent of how nearly chemical action has occurred—that it is the same for atoms straining at one another at their normal distance as for atoms on the verge of combination. And it may be argued in favour of this view that we really have some data, viz., these.

If it were not true, results obtained by Pellat's method could not be expected to agree exactly with those obtained by Kohlrausch's (of which Ayrton and Perry's or Clifton's may be taken as the best examples). Now results obtained by these different methods do agree very fairly well; exact agreement cannot be predicated, for the most trifling circumstances cause large variations in the Volta effect, but no decided disagreement is observable. Again, if it were not true, the Volta effect observed when two metals far apart in the series (*e.g.* zinc and platinum) were employed would be inconsistent with the results obtained by using metals nearer together, say, zinc and tin, or tin and platinum; and if this were so, the metals could not be arranged in the linear series which eighty years ago Volta showed they could be. These arguments throw no light on what may happen *just* before actual combination, still they are encouraging as far as they go.

17. Let us therefore endeavour to suppress further qualms, and calculate a series of metal-air contact-forces from the heats of combustion; remembering that all we have to do, in order to convert heats of combustion per dyad gramme-equivalent into volts, is to divide by $\frac{19320 \times 10^8}{42 \times 10^6}$ that is by 46,000.

But the decision as to what numbers we shall take to represent heats of combustion is a matter of some difficulty, for not only do the numbers obtained by different observers for the same reaction differ, sometimes considerably, but it is not obvious when different oxides are formed which of them we are to consider as most applicable to the case of the Volta experiment. Perhaps one should take the most common or stable oxide; perhaps, seeing that no combination is supposed actually to occur, and, since the metal is, so to speak, in excess, it is most reasonable to take the lowest oxide which the substance will form. It may be that the data are not known for this; it may even be that they have only been obtained for the hydrate instead of for the oxide.

I must therefore do the best I can, and quote several numbers (Table A) wherever there is obvious doubt. I imagine that J. Thomsen's are the most reliable when they are available.

But it must be remembered all through, that since it is only the *tendency* to chemical action which is the cause of the Volta effect, whereas combination heats are obtained by permitting or causing the combination to actually occur, the numbers obtained by calculation are not likely to be quite right; and they may be expected to err on the side of excess, the calculated number being higher than the actual value if directly observed.

Numbers obtained from unsatisfactory oxides and hydrates like those of aluminium, arsenic, and bismuth, are not likely to be useful for our present purpose. I know of no better data yet available however.

It is now easy to write down a Volta series obtained by pure calculation from heats of combustion. We can then see how far it agrees with the results of direct experiment. The principle on which I determine which of the preceding numbers to select is simply to choose Thomsen's when it refers to the simplest oxide, and in other cases to take what one can get. Metals about which there is obvious uncertainty, as for instance sodium, aluminium, bismuth, &c., are omitted.

Calculated Volta Series.

Lithium and Magnesium	3·0	Nickel	1·32
Potassium	2·95	Lead	1·15
Calcium, &c.	2·84	Thallium	·92
Zinc	1·85	Copper	·81
Iron	1·64	Mercury	·67
Tin	1·46	Palladium	·5
Cadmium	1·43	Silver	·13
Cobalt	1·38		

To compare this series with those obtained by experiment we may as well take zinc as the metal of reference, and write down the Volta effect between it and the other metals, first as abstracted from the above table, and then as found by different observers. Strictly, one ought first to subtract Peltier forces from the observed numbers before comparing them with theory; but these forces are too small to make any appreciable difference.

Volta Effects in Air.

Comparison between Theory and Experiment.

Metal pair.	Calculated from heats of oxidation.	Observed by				
		Pellat.		Ayrton and Perry.		Clifton.
		Clean.	Scratched.	Using commercial zinc.	Using amalgamated zinc.	
Zinc :—						
Tin	·39	·25	·35	·28	·46	
Lead	·70 or ·65	·15	·31	·20	·35	
Iron	·21 or ·4	·56	·70	·60	·74	·75
Nickel	·53	·47	·63	...	...	
Copper	1·04 or ·9	·71	·86	·75	·89	·85
Mercury	1·18	...	...	1·06	1·20	1·07
Silver	1·71 or 1·58	·91	1·12	...	...	
Platinum	.....	...	...	·98	1·13	

The alternative calculated number sometimes given is merely to show the kind of variation probable in those cases from uncertainty of data. In each case of agreement the calculated number is a little higher than the observed, as was to be expected. No reason occurs to me for the breakdown and apparent interchange, in the case of lead and iron, but such vague guesses as may occur to every one.

Measurements of the E.M.F. between clean metals plunged into distilled water or weak acid, have been made by Clifton and by Beetz.* I suppose one is justified in calling them

Volta Effects in Water.

Metal pair.	Calculated from heats of oxidation.	Observed by	
		Beetz.	Clifton.
Zinc :—			
Copper	1·0	·98	82 to 92
Silver	1·7	1·23	
Platinum	1·8 or less.	1·52	1·3 (Smee).
Sodium amalgam :—			
Zinc	1·0	·78	
Copper	2·0	1·79	
Silver	2·6	2·05	
Platinum	2·8	2·31	

I do not wish to blink the fact that some of the numbers in the former of the above tables afford a rather poor support to my theory; but it must be remembered, on the other hand, that they are not relative numbers only that we have calculated, but absolute; and the fact that the heats of combustion reduced to volts are numbers of the same order of magnitude as the Volta effects, is of itself a strong confirmation of the belief that chemical strain at the air contacts is the real cause of the apparent contact force at the junction of two metals.

The agreement of the numbers, though not exact, seems to me too close to be the result of accident. One may, I think, claim that the hypothesis whence the calculated numbers are obtained is justified by the figures as far as they go. It is not put forward as a completed theory, but only as a first step to such a theory. I believe it to be a step in the direction of the truth, but it requires working out and elaborating by a scientific chemist.

[TO BE CONTINUED.]

REPORT ON ELECTRIC LIGHTING IN THE CITY.

(CONTINUED FROM PAGE 483.)

I will consider the results obtained under the two heads of Efficiency and Economy.

A. EFFICIENCY.—It is not too much to say, that at the present moment there is not one single thoroughfare in the City of London, or in any of its suburbs, thoroughly and efficiently illuminated. Wimbledon is lighted by oil lamps, having one-inch flat wicks, and burning petroleum oil, of their kind very good when well trimmed and well supervised, but fixed at such distances apart that they cease to become illuminators, and act solely as guides. Carelessness and inattention, however, frequently render them useless and offensive. They are left to burn themselves out, instead of being turned out like gas, and lamps are frequently found burning vigorously in bright sunlight. They are not interfered with by weather so much as gas lights. The light they give when in good order is very steady. Their theoretical illumination is fifteen candles, but their average light is only twelve candles. The gas lamps in the city are supposed to give an illuminating power of fourteen candles, when burning five cubic feet of gas per hour, and they do so when burning steadily and regularly in the laboratory, but when placed in the street lamps the supply of gas becomes irregular through age and dirt in the burner; the flame flickers about through imperfect combustion and through draughts, the lanterns become dim and the glass, therefore, obstructive, and the result is that the average light given is only ten candles instead of fourteen. An electrical glow lamp avoids all the defects of the oil and gas. The light is absolutely steady, and can be regulated and controlled, turned on and off at will. It is independent of weather, but age gradually deteriorates the carbon filament until it breaks. Its average life however is 1,000 hours, and it is replaced with ease and rapidity. We can make oil, gas, or electric lamps to emit any amount of light we desire within reasonable limits, but as we increase the illuminating power of oil and gas we have to increase the sizes of the lanterns and posts until they attain impracticable dimensions. With electricity, however, we have a power of concentration of light that no other illuminant possesses. The same sized lamp can be made to give any light from one to one hundred candles, by simply varying the strength of the current or the size of the filament. It can be fixed anywhere or anyhow. It is not essential to obstruct its light by glass or shades. In fact it is astonishing how thoroughly the glow lamp lends itself to the illumination of our streets, and how immensely superior it is for this purpose to oil or gas. Experiments were made with glow lamps of 10, 20, 30, 50, and 60 candle-power. That which lends itself best to street lighting, and which gave the most favourable results, was Messrs. Woodhouse and Rawson's 50-candle lamp. The most brilliant

* *Ann. der Physik*, x., p. 348 (1880).

Digitized by Google

results were given by the Bernstein 60-candle lamp, but its commercial efficiency was inferior. Table A indicates the efficiency of these lamps when incandesced to their nominal candle-power, but if they be incandesced above their normal power, their efficiency increases while their durability diminishes.

TABLE A.

Lamp.	Electromotive force. Volts.	Current Amperes.	Candle power (actual).	Efficiency Watts per Candle.
Swan	51	0·71	11·3	3·2
Swan	49	1·31	19	3·37
Woodhouse and Rawson	55	1·15	20·2	2·35
Woodhouse and Rawson	60	2·33	53	2·4
Bernstein	25	5·25	33	4·0
Bernstein	39·75	6·3	66	3·8
Maxim	80	2·16	50	3·45

No experiments have yet been made to determine the life of lamps at these different states of efficiency, though it is perfectly well known that the higher their efficiency the shorter their career. Since, however, the higher the efficiency of the lamp the less the number of watts per candle consumed, it is evident that there must be some limit for every lamp where the value of its durability just balances the value of its commercial efficiency. It may be a very creditable performance to obtain 2,500 hours' life out of a lamp, and this has been done; but this may have been obtained at an expenditure of power that was commercially ridiculous. The value of the lamp may have been wasted over and over again. The cost of the production of energy is, as a rule, greater than the mere lamp renewal, and the efficiency is of far greater moment than the life. An ordinary 20-candle glow lamp has a guaranteed life of one thousand hours. This, at 4s. per lamp, is equivalent to ·0025d. per candle hour. The price of a watt in London is ·002d. per candle hour, hence a 20-candle lamp costs in power ·006d. per hour; thus it is easily shown that, if the efficiency be reduced from three watts per candle to two watts per candle, the life might be 555 hours, instead of one thousand hours, without any alteration in the cost per candle-power per hour, whereas if we were to maintain the lower efficiency, the value of the lamps would be wasted in energy. It is therefore clearly economical to work at a high efficiency, though it entails a shorter life, and the cheaper the makers turn out their lamps the more easily can this be done. Were it not for the inconvenience of frequent renewals, a short life would be unobjectionable, but as it is, renewals, if frequent, would become a nuisance. The constant renewal of the arc lamp is its great inconvenience. Hence there is some state of efficiency for every glow lamp where these advantages and disadvantages are balanced. The duration and scope of my experiments at Wimbledon did not enable me to test this point. The importance of this question cannot be underrated. The practical efficiency of the arc lights in the City of London is nearly two watts per candle, and they are renewed every eight hours. The practical efficiency of the glow lamps I have used at Wimbledon is a little over two watts per candle, but I never had to renew them at all. If I had incandesced them a little more I might have had to renew them every hundred hours, but I should have obtained the same efficiency from them as from arc lamps. Hence the supposed economy of the arc over the glow lamp disappears. An efficiency of one candle per watt is not unattainable in glow lamps, and when that is reached it will equal an efficient arc lamp in economy.

B. HOW CAN GLOW LAMPS AND THE LIGHT THEY EMIT BE BEST DISTRIBUTED?—I have said that a glow lamp of 50 candle-power lends itself best to street illumination. These lamps were fixed at various distances apart, and at various heights above the ground. They were placed by the sides of the streets and scattered in various ways, but the best effect was produced when they were suspended over the centre of the roadway, 25ft. from the ground. If such lamps were placed in dioptric globes 50ft. apart, the light would be evenly and uniformly distributed. A very great number of reflectors of different patterns were tried, and their effect measured. Diagram No. 3 illustrates some measurements taken. The best effects, as judged by the eye, were obtained by bright nickel-plated iron discs of 18in. diameter. In dealing with the distribution of light from an economical point of view, I must deal partially with estimate and calculation. A horse-power in London can be supplied at one penny per hour for a day of six hours. Taking the net efficiency of the machinery and conductors at 67 per cent. or 500 watts to the horse-power, the cost of a watt hour is ·002d.; although we may hope eventually to obtain in glow lamps one candle-power for each watt expended, we cannot estimate for less than 2·5 watts per candle at present. Hence one candle-power by incandescence costs ·005d. per hour, and 50-candle lamps cost ·25d. per hour; therefore, three 50 candle-power lamps, or 150ft. of street, cost 0·75d. per hour. On the other hand, one candle per watt is easily obtained by arc light, though the average useful light from the Brush lamp is by measurement not more than one candle per 1·9 watt. Let us take it at 1·49 watt per candle, or one actual horse-power per lamp, then each 150ft. of street costs one penny per hour, while when illuminated by glow lamps, it costs only 0·75d. for the same time.

THE COST OF WORKING.—The experiments at Wimbledon were carried on from March 21st to June 21st, 1884. The nature of the experiments involved considerable variation and irregularity in the working, but I was able to obtain eight weeks' continued working of 76 lamps, of 20 candle-power, and to reduce the cost of working to an average of six hours per night, and therefore to so much per lamp per hour. Table B gives the result:—

TABLE B.

EXPENSES OF 76 LIGHTS FOR EIGHT WEEKS.

		£	s.	d.	Per night of 6 hrs.:	s.	d.
Coal	7 h.p. at 4lb. per h.p. per hour at 18s. per ton	3	15	6	1½cwt.	1	4
Wood	2d. per night	0	10	6	.....	0	2
Oil	3½ gallons at 4s. 6d.	0	16	6	Oil and waste, say	0	4½
Waste	8lb.	0	4	0			
Lamps	*76 lamps at 1,000 hours' life at 5s. per lamp.	6	8	0	Lamps, say	2	3½
Ditto	Repairs	0	6	0	Repairs, &c, say	0	1½
Brushes	Brushes at 3 months per set	0	2	0			
Wages	Lampman	9	4	0	Wages	8	8
	Driver	11	12	0			
Interest and depreciation	Interest and depreciation on £500 at 10 per cent.	7	6	0	.....	2	6
	Total	40	4	6	.....	15	5½

* This life is guaranteed by the makers.

This is equal to 0·408d. per lamp per hour. Now, since the same staff could have attended to 400 similar lamps, Table C shows what the cost would have been had that number of lamps been used:—

TABLE C.

EXPENSES PER NIGHT OF 76 LIGHTS FOR EIGHT WEEKS.

		£	s.	d.
Coal	40 h.p., at 4lb. for 6 hours = 8½cwt.	0	7	8
Wood		0	0	2
Oil	2 pints and waste	0	1	3
Repairs, &c.		0	0	4
Lamps	Renewals, at 1,000 hours' life, at 5s.	0	12	0
Wages		0	8	8
Interest and depreciation	at 10 per cent. on £1,600	0	8	9
	Total	1	18	10

= nearly 0·2d. per lamp per hour.

DIAGRAM 3.

Digitized by Google

The actual cost of 76 lamps was less than ½d. per lamp per hour; the estimated cost of 400 lamps is nearly one-fifth of a penny per hour, the same price as an ordinary gas burner, burning five cubic feet per hour, when gas is 4s. 2d. per thousand cubic feet. This, however, is independent of rent. Rent would probably bring it up to one fathing per lamp per hour. Let us take it at one farthing per lamp of twenty candles per hour. It follows that a 20 candle-power glow lamp can be maintained for the same price as a nominal 14 candle-power gas burner, such as those used in the streets of the City. But in this calculation no allowance has been made for capital, supervision, accident, insurance, &c., items very difficult to allow for, but all of which are contingencies which must be taken into consideration. I prefer to take as my unit 10 candle-power, not only because I experimented with such lamps, but because it is the mean average of the existing street gas lamps, and a very convenient number for glow lamps. Taking all facts into consideration, I think I am fully justified in estimating the total cost of producing 10 candle-power by glow lamps, for six hours per night at not less than ½d. per unit per hour. It is probable that this would be too high if we employed 50-candle lamps, for the charge on renewal and depreciation would be diminished, owing to there being fewer lamps to renew; but I would rather have my estimate too high than err on the wrong side. The result is that when we compare lighting our streets by gas and by electricity, the cost of each at the present price charged for gas is about the same, but the conveniences and advantages of the electric mode are so manifestly superior to the gas, that it is difficult to justify a continuance of the present method. It will perhaps be instructive to record the accidents and failures that occurred during this three months' trial:—1. March 21st—Bearing of dynamo got very hot. No stoppage. 2. March 22nd—Lacing of belt gave way. Three minutes' stoppage. 3. April 1st—Parallel or group gave out, owing to lamp breaking or being broken. Circuit stopped for 39 minutes. No automatic compensation in use at this time. 4. April 7th—Another parallel gave way during experiment, owing to imperfect adjustment. 5. April 29th—Another parallel gave way, owing to a change of dynamo. [N.B.—After this, compensating secondary cells were inserted in each group, and this liability to failure cured.] 6. May 12th—Three lamps went out, probably from stone throwing, but compensating cells prevented any breakdown. 7. June 10th—Coil gave way in dynamo—all lights out. These were all the accidents that took place, and were all due to preventible causes. The last failure would not have interfered with the lighting had there been, as there ought to have been, a spare dynamo, for the defect was observed long before it interfered with the lighting. The arrangements were made, and the experiments conducted by Mr. Albert H. Howard.

(TO BE CONTINUED.)

B.T.K. STORAGE BATTERIES.

The following is the report of Prof. G. Forbes to the Consolidated Electric Company on these batteries:—

"GENTLEMEN: I have spent a long time in experimenting on the B.T.K. Storage Batteries. I am now in a position to state the efficiency and commercial output of the batteries tested, and to judge of the action of the master-cell, and the general working of the cells. For these experiments I used Sir William Thomson's graded galvanometers, and two Ayrton and Perry instruments. I calibrated the galvanometers for measuring current by frequent comparisons with a voltameter, and the galvanometers for measuring differences of potential by passing a known current through a known resistance. It has been very usual to test the efficiency of an accumulator by a single charge and discharge. I do not consider that this is a trustworthy method. I took the mean of five charges and five discharges in succession, and the observations during this time numbered 960. I used 18 cells of the battery in series. The batteries were locked in a room of which I held the key. The experiments for efficiency lasted a fortnight. I invited your *employés* to supply me with the charging current which they preferred to use, and I discharged at the rate which they adopt in practice. I charged in every case until the master-cell acted, and discharged until the E.M.F. had fallen more than would be convenient in practice. On the first day the current was not strong enough, and the master-cell did not act for about 18 hours. The master-cell generally acted well if a proper current was supplied, but it acts earlier or later as the current is stronger or weaker. If the current be properly regulated it acts well. The experiments gave the following data for calculating the practical commercial efficiency of the battery:—

Total in 1st charge.....	10,905·32	
,, 1st discharge		3,779·25
,, 2nd charge	5,195·20	
,, 2nd discharge		3,804·27
,, 3rd charge	5,302·63	
,, 3rd discharge		2,835·48
,, 4th charge	3,997·51	
,, 4th discharge		1,829·63
,, 5th charge	2,632·39	
,, 5th discharge		4,635·64
Total Charge	28,033·056	
Total Discharge		16,884·274

True commercial efficiency 60·23 per cent.

"The efficiency of batteries is sometimes given by using the E.M.F. of the batteries instead of the difference of potential between terminals. This is really of no value, but in this way my experiments give the nett efficiency = 67·69 per cent. Several of the cells were not in perfect order, and lost their E.M.F. entirely; owing to this cause the efficiency given above is not so high as it would have been with better cells. In order to measure the maximum output of these batteries, I charged them fully without the master-cell, and measured the work given out. I thus got a total of 263·2 ampere hours. But in this time the E.M.F. had fallen very low indeed. The practical output was finished in seven hours, by which time the E.M.F. had fallen 18 per cent., and the output was 132·01 ampere hours.

"The weight of the lead plates in a single cell was—

7 negative plates = 27lb. 3¼oz.
8 positive do. = 30lb. 11oz.

Total..... 57lb. 14¼oz.

(N.B.—I use the terms negative and positive as electricians use them).

"Thus we may say that the useful output is 2·3 ampere hours per lb. weight of plates. But this weight includes the supports and terminals of the plates. It must also be remarked that reports are often made of the output of storage batteries in which the weight of active material (the lead salts) is alone included, and the lead support of the plates is omitted; this is misleading. A certain amount of bulging was noticed in some of the plates after a lengthy discharge. This would not occur with these plates when properly used.

"In conclusion, my opinion is that these cells are good, and that their performance would have been better if they had been better treated before being placed in my hands. The inequalities in different cells would then not have appeared, and the injurious consequences would have been avoided. After I had completed the experiments recorded in the above report I was asked, in view of my statement that the cells were not in perfect order, to test another battery of 18 cells by a single charge and discharge under favourable conditions. The results are given below. In the foregoing experiments I had worked the cells under ordinary working conditions, charging them one day and discharging them the next day at a fairly rapid rate. I now undertook to charge them until they gave off gas, and then immediately to commence the discharge at a slow rate, taking observations continuously at intervals of ten to thirty minutes. This involved continuous observation during 26 hours. I have already stated that I do not consider the efficiency as determined by a single charge and discharge to be capable of the great exactitude which I had aimed at in my five charges and five discharges previously. In order, however, to make the result as reliable as possible under the circumstances, I commenced work by charging for 45 minutes, and then discharged for an hour, and noted the E.M.F. I then charged for nine hours at the rate of 22 to 30 amperes, *i.e.*, from 1:40 p.m. to 10:10 p.m. on 16th March, 1885. I then discharged for about 14 hours at the rate of about 13 to 14 amperes. At the end of this time the E.M.F. had fallen down to what it was in my preliminary discharge. The discharge lasted from 11 p.m. March 16th until 1:15 p.m. on March 17th. The charge put in was not the total charge which might have been given had the object been to measure the capacity instead of the efficiency of the accumulators. The E.M.F. fell only 14 per cent. during the period of discharge, so that the batteries still retained a considerable charge; but in practical working the limits of charge and discharge which I used ought not to be exceeded. The result arrived at was that the charge given to the accumulators was 242·18 ampere hours, and the discharge to reduce it to its primitive condition was 193·48 ampere hours, which gives the efficiency in ampere hours at 79·89 %. But this is not the true efficiency, because the E.M.F. and the resistance of the battery must be taken into account. Calculating the results in this way, the true and practical efficiency comes out 69·02 %. I am able to form no reliable opinion on the probable life of these batteries, as it is impossible, without tests lasting over years, to obtain data upon which to form an opinion. I think it right to point out that my method of testing (putting a number of cells in series) is far more severe, and is certain to give less satisfactory results, than if I tested a single cell. But it is the only method which gives a satisfactory idea of their action in practice, as it is usual to employ a number of cells in series."

THE COMMITTEE ON OVERHEAD WIRES.

The Select Committee of the House of Commons for inquiring into the law relating to telephone, telegraph, and other wires resumed its sittings on Thursday, the 16th inst., Mr. G. W. Russell presiding.

The first witness called was Mr. JOHNSON, the chairman of the Commissioners of Sewers of the City of London, who was examined by the Chairman. He said he had had occasion officially to give much attention to the use of wires in the city, and his opinion was that legislation was much needed. Asked whether it was preferable to have underground or overhead wires, he replied that if it were possible to put all the wires underground they believed that would be undoubtedly the best course, but the difficulties were very great, if not insurmountable, chiefly on account of the enormous cost. They also thought that the difference between the action of the telegraph and telephone wires would warrant separate treatment, so that the telephone must be overhead and the telegraph underground.

You speak of the expense of having the wires underground, would it alter the telephone business?—Yes; if the whole of the expense of putting the wires underground were thrown upon the telegraph and telephone

Digitized by Google

companies at first, the cost would be too large for them to encounter; still, if the expense were undertaken, we have an impression that the telegraph and telephone companies would be able to pay the necessary amount to cover the original expense.

Upon whom would you charge the cost?—It is not a subject which we have really discussed to any great extent. My own idea is that it should not be out of the rates, but that the rentals charged for the wires should be made to recoup the original expense.

What is your view of the administration of the law upon the subject?—At first I would entrust it to the local authority who had the control of the streets.

You would not be prepared to give an opinion as to what should be the controlling authority in any part of London out of the City?—In the City and elsewhere the staff is existent and the means are at hand for the purpose of exercising any amount of control. Delay would be avoided by utilising these staffs.

A great many witnesses have stated that it would be impossible to carry on the business of the companies if they were subjected to the control of many bodies, and they wanted to be placed under the Board of Works, or one municipal body?—It occurs to me that a difficulty would arise if too much discretion were given; but if the Act of Parliament were to define how the wires were to be carried, either above or below ground, and some definite directions were given, it would not be beyond the scope of any local authority to see that the restrictions were observed.

It has been recommended by many witnesses that all the bye laws affecting these wires should be subject to the control of one of the departments of the Government—the Board of Trade or the Local Government Board?—I should think it extremely necessary.

Sir JAMES HOGG: Who is to pay for the cost of these subways?—My idea is that the capital cost should be provided by some such body as the Loan Commissioners; at any rate, it should not be out of the rates.

Would not the putting of subways all through London be an absurd expense?—I do not advocate it. I believe it to be too large an undertaking; at all events, at present.

As regards the inspection, the different companies would have to pay a certain amount to any body for that work?—Certainly; there was no one body in London of sufficient experience or knowlege of the wants of London to qualify them for taking over the general control of the regulations.

Then, if there is nobody at present existing who can make bye laws, to whom would you give that power—the House of Commons could not undertake it?—I would allow each local body to use its local knowledge for the purpose of making such bye laws as are especially suited to their district. I think it would be quite possible to make a code of bye laws.

So you think that 28 sets of bye laws made by 28 different bodies would be the most convenient tribunal for the Companies to go to?—Yes, for the matters relating to each district. They must accommodate their work to the requirements of the district.

By Mr. GRAY: The gist of your evidence is that you would preserve the regulation by local authorities, while securing by the authority of a confirming body such a conformity of regulations as would be necessary for the discharge of business?—Yes.

Do you think that subways should be introduced into the City?—No. The word "subway," as I understand it, means a long tunnel in which a man can walk, and in which pipes and wires can be laid. The construction of such subways would involve cost of immense magnitude, and I should disapprove of it. I think the system of carrying wires close to the kerb underground, as has been done in the case of the telegraph wires, might be adopted with advantage.

Are you aware that the Post Office wires in the City are as a rule systems of trunk wires, and that the telephone system splits up in order to enable the telegraph wires to be carried to individual places?—If your proposal involves the opening up of numbers of streets for these wires going to individual establishments, how do you view the question as regards the traffic?—The use of gas and water pipes afford some parallel.

But these wires would be laid as occasion might arise at different times?—Of course there is that difficulty.

In continued examination, witness said that the increase in the number of overhead wires was most alarming. There were now ten times as many wires as there were a few years ago, and in squalls some of the posts were so overloaded that they deviated from the upright. In the case of a heavy hail or snowstorm a whole system might be swept away.

The CHAIRMAN: Do you think the lines running by the side of the kerb would be more desirable than the overhead wires?—I think they would be a great improvement.

We have heard that there is a scientific difficulty in the way of carrying telephone wires underground. Do you think the difficulties to that are so great as to be insuperable?—I am afraid that the telephone wires must remain overhead. I would try to relieve the strain by putting the telegraph wires underground.

Lieut.-Colonel HAYWOOD, engineer to the Commissioners of Sewers, was the next witness. In answer to the Chairman, he said that in his official capacity he had seen with alarm the rapid increase in the number of overhead wires in the metropolis, an increase so large that these lines now constituted a public nuisance. A return giving the number of the wires in the City showed that across Moorgate-street there were 320 wires, across Coleman-street, 320; across Leadenhall-street, in a length of 1,414 feet, 240; across Fenchurch-street, in a length of 1,700 feet, 160; and across Queen Victoria-street, in 2,000 feet, eight large cables and 408 wires. At Ludgate-circus you could count 142 wires and two cables. In King-street, leading to the Guildhall, there were six cables and 74 wires in a length of 520ft. Cannon-street had seven cables and 360 wires. In some streets there were from 1,200 to 1,500 wires to the mile, and the mean for the City was about 1,000 to the mile. In many places they seemed to darken the air.

You speak with alarm as to the increase of these wires. Have you, in your own experience, heard of any accidents?—There have been extremely few accidents—I have only heard of two. Of course, at present everything is new, and the atmosphere has scarcely had time to work upon the wires. Further examined, witness said that ordinary wires would probably need extensive repairs in 10 or 12 years. The durability of copper wires was much greater. He had not heard of any accidents from the snowstorm of a few weeks ago.

You are of opinion that danger is to be anticipated?—Of course the risk will increase in proportion to the number of wires and in proportion to the number of persons in the streets. The latter reason increases the element of danger in the City. The night population of the City is very trifling—not more than 50,000 or 60,000. But for ten hours in the day there are about 350,000 people in the City, and the population passing in and out of the City daily is about three-quarters of a million.

To what causes besides deterioration should you look for danger from the wires?—Wind, snow, and fire. A fire may occur in a house supporting the wires.

You are of opinion that the method of carrying the wires underground ought to be adopted?—I think so; I think that the public ought not to be subjected to the risk of accidents, although I am bound to say the risk is not extremely great at the present time. I also think the air ought not to be darkened by these wires. The expense of laying the wires underground must, of course, be very great; but in the interest of the public it must be borne.

But it has been said that the expense would be fatal to the development of the telephone system.—I have no doubt the companies would object to the increased expense, but I doubt whether it would be prohibitory. My own opinion is that there ought to be in all the main streets of the metropolis subways such as the Corporation of London constructed in Holborn, and that in these subways should be placed not only these wires but gas-pipes and water-pipes, the Hydraulic Power Company's pipes, the Electric Lighting Company's pipes (whenever they come into existence, as they will do when the ridiculous Act of Parliament is repealed), the Pneumatic Despatch Company's pipes, the Pneumatic Block Company's pipes, and all other wires and pipes.

Your Chairman summed up in favour of underground wires for telegraphs and overhead wires for telephone purposes. You do not agree with that?—No; I would have them all underground, and have subways large enough for the purpose. I believe that this is the only way of getting rid of the danger I anticipate.

Have you any knowledge of the other schemes which have been suggested for minimising the danger?—Yes; I have heard of one for putting up large candelabras in front of houses, and another for putting up posts along the public way. In the first case there would have to be compensation provided for persons who objected, and the second scheme would be inconvenient as narrowing the footpath.

You have admitted that the plan of making a subway is a costly one. On whom would you propose to throw the expense of construction?—I can scarcely say. Certainly the local authority ought to have the control over them, and the cost must ultimately be borne by the users.

Have you any views as to the proper controlling authority in London?—In my opinion the general control should be placed in the hands of the Board of Trade, and the supervision of the execution of their regulations should be entrusted to the local authorities. The Board of Trade have a control over the gas and water companies, and I see no reason why their jurisdiction should not be extended to the companies owning these wires, though I see very great difficulty in anybody cuntrolling the wires so long as they are carried along the tops of the houses. The best way to guard the public against danger under the present system would be to impose a penalty of from £100 to £500 for every wire that falls, whether anybody is injured or not.—In further examination witness said he thought the work of constructing these subways might be undertaken by the gas companies. At present these companies were compelled, on reaching a certain dividend, to reduce their charges. He thought the reduction might for a time be dispensed with, and the sums thus rendered available should be devoted to subways such as he had mentioned. Of course this would be open to objection as a tax on the users of gas, but somebody must be taxed for it, and it was his experience that there was less objection to indirect than to direct taxation. Several provincial authorities were in the habit of devoting gas and water rates to local improvements.

Mr. GRAY asked whether witness had formed any opinion as to the cost of the subways?—Witness answered that proper subways could hardly be constructed for less than £40,000 a mile. He did not think that the proximity of the respective wires would interfere with their proper working. It would of course be necessary for the wires to emerge at places.

Would not your proposal double the charge to those who use the telephones?—I dare say it would, but I do not think the charge would be prohibitory.

You think the telephone would be equally used at £40 a year as at £20?—Of course there might not be quite as many customers at the higher charge as at the lower.

By Sir J. M'GAREL HOGG: It would be quite practicable to make subways in the crowded thoroughfares of the city of London, if it were decided to face the inconvenience and expense. He was taking into consideration the whole group of wires and pipes. He did not think it would be worth while to go to great expense for these wires alone.

Mr. FOWLER, Vice Deputy Chairman of the Metropolitan Board of Works, said that the attention of the Board had been directed to the possible inconvenience and mischief which might arise from the development of the systems of overhead wires. In view of the attempt of the United Telephone Company to obtain legislation on the subject, he might state that the Board considered it desirable that the telephone companies should be subject to the control of a central licensing authority, and that a record should be kept of every wire erected. It was not the wish of the Board

Digitized by Google

to fetter in any way the development of an important commercial undertaking which was now becoming a public necessity, and he fully admitted that everything should be done to encourage its extension. He objected to the proposal to grant to the Companies a right of compulsory attachment, but did not think that compensation should be paid to owners in cases where lines passed over without touching property—that would only be an ordinary case of way leave. He thought the danger from overhead wires had been greatly overrated, and that proper supervision would be sufficient to secure reasonable security from accident. The only difficulties in the way of taking wires underground were the expense and the inconvenience resulting from the opening of public roads; but these objections were so serious that the scheme would be impracticable.

At the conclusion of the evidence of this witness, the Committee adjourned until Monday, the 20th inst.

On Monday the Select Committee of the House of Commons resumed its sitting on the law controlling the telephone, telegraph, and other wires, Mr. G. W. Russell presiding.

Sir ARTHUR HOBHOUSE was the first witness called, and in reply to the chairman he said that he represented St. George's Vestry, and had been requested to give evidence with reference to the proper control of the wires. The vestry had had very little experience of wires, because, while the wires fell, and caused an obstruction, they had no jurisdiction. They had had complaints of wires falling, but no personal injury had resulted. Some of the vestries had desired that the control should be in the vestries themselves. St. George's had never contended for that, but they had desired that inasmuch as the matter was of great public interest and novel, and the law was entirely insufficient to deal with it, that there should be some public authority having the control over the laying and the maintenance of the wires. As to the sort of control to be exercised that was a question of considerable difficulty, and on which there was a great difference of opinion amongst the vestries. The St. George's Vestry could not see their way to ask that the vestries themselves should have a veto upon the establishment of a wire, because wires extended over districts larger than the jurisdiction of the vestries, and consequently conflicting views might arise. On the other hand, St. George's Vestry was strongly of opinion that the details of laying and maintenance of the wires were the proper subjects of strict local control. St. George's Vestry had passed resolutions on the subject as follows:—That it is necessary to create some central authority other than the existing local authority for the purpose of deciding whether power should be given to erect wires in cases where it is proposed to lay wires extending over an area subject to more than one local authority; that such central authority should be either the Metropolitan Board of Works or Board of Trade; that such central authority should have jurisdiction over the erecting of wires from point to point or within certain lines of deviation; and that all questions relating to the mode of erecting such wires and to maintenance and supervision should be left to the decision of the local authority; and further that all questions relating to wires entirely within the area subject to the local authority should be left to the decision of the local authority. To point out the cases in which there was a dividing line between the jurisdiction of the local authority and the central authority, there was the Electric Lighting Act where the whole power was vested in the vestry. The Act said "that notwithstanding anything in the Act the undertakers shall not authorise any line along, over, or across any street without the consent of the local authority." A provisional order might overrule that, and in fact that was done when the vestry remonstrated, and the Board of Trade inserted provisions maintaining the authority which was given by the Electric Lighting Act. There the Board of Trade gave the power to lay the line, and when the line came to the streets then the local power fastened upon it, and nothing could be done without the consent of the vestry.

By Mr. GRAY: The Electric Lighting Act gave to the vestries absolute prohibition.

By Mr. FIRTH: There is no control at present unless there happens to be an annoyance, and then the vestry has jurisdiction. A central authority should have power to make bye laws, but the vestries should have a control of details of maintenance and supervision, supposing the owner of a wire proposed to carry it across the street at a span or angle which the vestry considered too large. The local authority should have jurisdiction in such a case as that.

Would not you lay down that there should be some similarity of general regulations?—That depends upon the subject. You could not make a regulation to have all overhead or all underground wires, because some might be more advantageously placed overhead and others underground; or you could not regulate the span or the strength of the posts, which must depend upon the weight and the thickness; and all these matters were strictly within the jurisdiction of the local authority in each case. The power that should be given to a central authority would be to lay the wires from point to point or within certain lines of deviation. For instance, a company should receive power to place wires from Westminster Bridge to Paddington Station, and the central authority should have the power of saying that they should not be erected in over crowded places. The central authority should not frame bye laws on every subject, for some discretion must be left to the vestries. They should have complete powers as to the ownership of the wires and inspection, and as to the strength of posts, and this would involve some registration, but he would not make it compulsory to register. He had had a wire placed over his own house; but he intended to ask the company to enter into an agreement to remove it whenever he desired. In a company with which he was connected they had demanded 6d. a yard as rent for the wire, and this had been agreed to. That was merely to preserve their legal rights.

By Mr. GRAY: The vestries had no power outside the area of user. At present no damage had been done by the wires in St. George's district.

If the wires were a source of danger to the public would not the local authority then have power?—No. If it could be shown that there was imminent danger the local authority would have power, because it would come under the head of annoyance; but that could not be shown.

By Colonel ALEXANDER: How do you have the right to say anything to a wire going over your house, through the air as it were?—My house gives me the dominion of the moon.

Mr. M'CULLAGH TORRENS: You say that you have a right from the foundations of your house to the moon?—Further than that—from the centre of the earth to the moon; that is my common law right.

By Mr. DICKSON: I do not oppose overhead wires universally.

Is it possible to have a system of underground wires in connection with the development of telephones?—If there were subways that would be all right, but then there are none, or very few. Subways would be very expensive, and it is a simple matter of expense.

Mr. CHARLES MOSSOP, chairman of the Electric Lighting Act Committee of the Chelsea Vestry, said that the vestries and district boards should have authority over the wires. The dual authority of the vestries and the Metropolitan Board was inefficient, and caused great delay. They had passed the following resolution:—"That the authorities to sanction the laying of telephone wires in the metropolis should be the vestries and district boards, and not the Metropolitan Board of Works, and that the dual authority suggested by the Metropolitan Board of Works has already proved inefficient, and that it leads to great difficulties, and causes delay" That resolution was sent to all the vestries and district boards, and up to that morning they had received fifteen replies, and thirteen were in favour of this resolution. The local boards must necessarily know a great deal more than the Metropolitan Board, because the former had several local officers, whereas the Metropolitan Board had only one. If the matter were put into the hands of the Metropolitan Board they would be receiving their information at second hand from the officers of the local boards. The question had practically been settled already, because under the Electric Lighting Act of 1882 it was decided that under no circumstances should the Metropolitan Board be the local authority, and that was carried out. Then the Telephone Bill included such places as Southampton, Manchester, and Leicester, and it would be monstrous to suppose that such places as these would tolerate the appeal to the Metropolitan Board of Works.

Sir JAMES HOGG: There is no idea of Leicester and Manchester being put under the Metropolitan Board. You are raising up an object to knock it down.

Mr. GRAY: It is not so irrelevant, for if there were an appeal in London to the authority and another appeal to a different authority for the country it would be an awkward affair.

The CHAIRMAN: I am bound to say that there would be a different appeal in the case of London and the Provinces.

WITNESS: The reason that I object to the Metropolitan Board is, first of all, because it is contrary to the precedent of the Electric Lighting Act, and, secondly, you get in the arbitrator business. Supposing a dispute arose between Chelsea and St. George's, and the matter were referred to the Metropolitan Board, Chelsea would have only one member to advocate its claims and St. George's would have two; and that would not be an impartial tribunal.

The CHAIRMAN: That is certainly a good point.

By Mr. GRAY: I have drawn up a report to the Vestry as Chairman of the Electric Lighting Committee on the United Telephone Bill, in which I say that, having regard to the value of the telephone to the commercial world and to the power which the Bill provides for the examination and testing of the wires, overhead wires might be used without danger to the public. However the Bill may limit the power of local authorities, it enables them to impose such prohibitive conditions as would either partially or wholly debar the parish from the advantage which telephonic communication affords, as the scale of subscription must of necessity be regulated according to the cost of construction and maintenance. The cost per mile of wires laid underground is £350, whereas overhead wires can be fixed at £10 per mile. With proper supervision these overhead wires could be made safe, and, with periodical testings, they could be efficiently maintained. Under such circumstances local authorities might give their consent to the limited use of overhead wires rather than insist upon the use of underground wires only, at a thirty-fold increase of the outlay, and consequent addition of cost to the user.

Mr. GREENWELL, of the Marylebone Vestry, was the next witness. He said their vestry had submitted a report to the other vestries, and ten of them had agreed to its principle. The chief features of that report were that no existing authority to be created would be better qualified to govern and control of the wires than the existing authorities represented by the western boards, because they formed the only authority under whom all the matters connected with the streets were governed; that the Board of Works should be the court of appeal in case of dispute between the companies and the local authorities, but in case Parliament should not sanction it, then that the alternative should be the Board of Trade. The decision of the court of appeal should be final. Every wire should be registered within six months after the passing of the Act; and to enforce the provisions of the Act there should be penalties.

In reply to Mr. FIRTH, witness said that the reason why they fixed on the Board of Works as the court of appeal was given in their report, viz., because the Metropolitan Board had been the body most identified with the local authorities, and distinctively representative of the people; but should Parliament not accept this proposal then they should like the Board of Trade to be substituted.

Mr. EDWARD BIRD, of the Fulham District Board, next gave evidence. He said they had not much experience of the wires in their district, as they had not many at present. A short time ago a wire broke, but no damage was done. If a resolution making underground wires compulsory

Digitized by Google

were passed, the expense would not be great in Fulham. He would place the control of the wires in the District Boards. The central authority should be the Board of Trade. Overhead wires should be tested and inspected by the Board of Trade, and should not be used until they had been so inspected. All the expense should be borne by the companies, as they were trading for profit.

Mr. ADAMS, of the Islington Vestry, said they felt that there was no control over the telephonic wires, and it was of the utmost importance that something should be done. His vestry preferred the Board of Trade to the Metropolitan Board as a court to refer matters in dispute. They had had a man nearly decapitated in Islington by the wires, and up to the present there had been no hurricane to test the stability of the wires.

The committee adjourned until Thursday.

THE CABLE SERVICE TO SOUTH AFRICA.

A meeting of persons in the trade of and connected with South Africa was held on the 17th inst. at the Cannon-street Hotel "To protest against the constant interruptions of the cable service to South Africa, and to take steps for having a duplicate line laid down to meet the exigencies and the growing importance of the trade with South Africa."

Baron ALBERT GRANT, by whom the meeting had been convened, stated that at the wish of two or three firms interested in the trade of South Africa, and also in his own behalf, he had ventured to ask them to attend that meeting with the object set out in the notice convening it. Probably that morning they had received a letter emanating from the Eastern and South African Telegraph Company, and signed by Sir James Anderson, the managing director, who stated that it was not true that there had been a continuous interruption of the cable service. He, however, contended that the reply of Sir James Anderson was no reply at all. He had said that the total number of interruptions spread over five years—though only three and a half years' dates were given—had been 107 days, and the length of each interruption was given. Now, if he (the Chairman) took these figures in a different way, the following were the results:—In 1882 the cable was interrupted twenty days, in 1883 for fifty-one days, in 1884 for twelve days; and already in 1885 the cable had not been in operation for forty days. He maintained that those figures alone showed the correctness of those who viewed the working of the cable as unsatisfactory. He presumed he was addressing a body of gentlemen more or less connected with South Africa, but whether with South Africa or elsewhere the experience was the same, that when once a cable service was established the manner in which all business relations with such distant place and England were conducted was completely changed to that which was the case before the cable was laid. Where commercial firms relied on correspondence they took their measures accordingly, and in the way of remittances, advices, and contracts, the business was conducted by post, and they were prepared for the interval of time necessary to go and come back; but he maintained that when once a cable service was established the public had a right to count upon a continuous service. Such interruptions as those mentioned by Sir James Anderson constituted a most serious inconvenience, and one calling for a remedy. The question was whether they were entitled to enter a protest, which, though a very mild proceeding, injuring no one, had often been found very efficacious. Many of the cables now in operation had been "loaded," as it was termed, at the time they were launched; and but for the "telegraph ring," which was formed many years ago, the telegraph enterprise at this moment in this country would be twice as efficacious as it was, and those who had invested in the undertakings would now be receiving a different rate of return. He did not know whether it was in consequence of that meeting or from pressure on the part of the Government, but Sir James Anderson now admitted that it was necessary to duplicate the line on the section which had been breaking, and he (the Chairman) contended that to that extent it proved that duplication was necessary. With what he regarded as an inferior service they had to pay a very high tariff—10s. a word. If an important colony like the Cape Colony, and all the places served by this cable, could not afford to have a continuous communication, practically free from the risks which he admitted were inseparable to deep sea cables, it was high time that they had such a service. That the Home Government should have been for 24 days without any communication from the Government of the Cape—from January 31 to February—at the time of Sir Charles Warren's expedition in Bechuanaland, and again since the 1st of April (that was, for 16 days) seemed monstrous, especially as the cable in question had been laid, not like other cables, depending on the traffic, but with the stipulation that the Eastern Company should get a *minimum* from the Government for some years. The object he had in asking them to attend that meeting was twofold—first of all, if they agreed with him, to protest against the present system being considered satisfactory, and secondly to say that there should be either a duplicate line along the same coast, or, what he thought better, another or alternate line on the West Coast of Africa, which would accommodate a great many places now without communication, and give them the great advantage of not being dependent entirely on the Eastern line, for they could then send messages by the Brazilian line, joining at Cape de Verde. But, whichever of those two alternatives was to be adopted, he intended asking them to say that a second line was imperatively required; for he doubted very much whether the duplication of the particular section which had been breaking was sufficient. If a second cable were to be laid alongside the present one, he thought that the same cause which had operated on the one would operate on the other. He would therefore propose that a second cable should be laid from the Cape by the West Coast, passing St. Helena, Cape Coast Castle, Sierra Leone, and joining at Cape de Verde, where it would connect with the Brazilian line. The third point was, how was this to be brought about? He did not know whether their meeting there and making a protest and sending it to the Eastern Company would be sufficient; but for his own part he should say that the proper thing to do was to sign a memorial to the Colonial Secretary, pointing out that he, having guaranteed a certain sum as revenue to the existing section of the South African cable, should either call upon the Company to duplicate the line as a necessity for the efficiency of the service, or that, if necessary, the Government should increase their subvention in the public interest, in order to enable the Eastern Company to lay another line, and to be able to do so without the entire risk (in consequence of there not being sufficient traffic) being borne by them. He was sure that no one having any connection with South Africa could be satisfied with the present service; and if that were the opinion of the meeting he would invite them to say so by passing the following resolution:—"That this meeting is of opinion that the service between England and South Africa owing to the frequent interruptions is not satisfactory, and that a repairing ship ought to be provided, so that communications may be kept up by steamer pending repairs, and that representations be made to the Eastern Telegraph Company on the subject."

A gentleman, whose name did not transpire, said that a repairing ship was now engaged in carrying messages.

The CHAIRMAN said that what was meant was that a steamer should be permanently established between the two points to carry messages quite independently of any repairing ship, so that the effect of an interruption of the cable might at all events be minimised.

Mr. BARKER seconded the motion.

Captain MILLS thought there could be no possible objection to the resolution. Everyone connected with South Africa must deplore the interruption to the cable, on account of the immense interests involved. There was a contract between the Cable Company and the Imperial and Colonial Governments which he thought must be regarded in considering the question. When the cable was first proposed by the Imperial Government during the time of the Zulu war, and when it became an absolute necessity, there was an attempt made to lay a cable by the western route; but that proposal fell through, and the contract which he held in his hand was entered into between the Company and the Imperial Government and the Government of the Cape. That contract provided that the cable should be kept open on certain payment of subsidies by the Imperial and Colonial Governments, and that in the event of the cable being interrupted for a period of three months at one time between Durban and Zanzibar, and six months at one time between Aden and Zanzibar, the subsidy should be stopped and not be paid by the Government. As would be seen by the statement of Sir James Anderson that event had never once happened, and the consequence had been that the subsidies had been regularly paid. He had always been of opinion that all cables should run parallel with the lines of steamers, and when this cable was proposed a great number of people at the Cape were of the same opinion, and urged that the cable should go, if possible, down the western route, and run parallel with the main line, in order that all messages might be conveyed at a time of a break in the cable. He was still of that opinion, and would be very glad now to see a cable laid on the western coast. But at the time contrary opinions prevailed, in consequence of the Zulu war and in consequence of Imperial interests, and the cable was laid the other way. Great pressure had been brought on the Company by the Cape Government, and a resolution was passed on the matter by the Legislative Council of the Colony on the 8th of August, 1883. This was forwarded to the Company, who had but one answer—which he supposed would be the answer to any protest at that meeting—which was that their interests and the interests of the public were identical, and that if there were breakages they could not help them, and that they would avoid them if they possibly could. No doubt there was a great deal in this answer; but it appeared to him as taking a practical view of the question that there were two proposals of relief. One was the proposal made by the Company, which was to duplicate that system of the line which had been breaking, which Sir James Anderson had said they were doing, and he had every reason to believe that they had adopted that course. The other way of relief was the one the Chairman proposed, which was a competitive line along the West Coast of Africa.

The CHAIRMAN desired to substitute the word "alternative" for "competitive," as the same company might have it.

Capt. MILLS observed that an alternative line would be a very large undertaking, and he was not at all prepared to say that the Government of Cape Colony, which was now paying, and would have to pay for the next fourteen years, a subsidy of £15,000 a year, would be in a position to subsidise a second line along the West Coast, more especially in view of the fact stated by Sir James Anderson, that the line on the East Coast, which was now a single line, did not pay. A heavy subsidy would under these circumstances be required by any Company who would lay down a cable along the West Coast, and he did not think the Government of Cape Colony was prepared to pay any large subsidy for such a line. In saying that, however, he was speaking without book, and the question had not been considered by the Colonial Government; but he gave his own opinion on the subject of the subsidy. At the present moment he did not see in the contract before them that there was very much to be expected beyond what the Eastern Company was doing. There had been representations made on the subject of the tariff, and on the subject of the interruption of the cable, and he must say that the Company had shown great anxiety in endeavouring to do all that they could to maintain the communication, and when it was broken to put ships on the line, and to carry on the messages.

Mr. SILVERBAUR said he belonged to the Cape of Good Hope. He could well remember, as Captain Mills had just said, when the discussion first arose with regard to laying down the cable that there was a general feeling in favour

Digitized by Google

of the western route, on account of the soundings which had been taken and the nature of the sea bottom along the western and eastern coasts. Some difficulty was experienced at the time respecting the subsidy. £15,000 was not very much for the Cape Government to pay; but still the question was in its infancy, and people had to be educated to the advantages of the cable. His eyes had been opened to that, and although at first he had thought that £15,000 was a very heavy sum to pay, as soon as the cable had been at work he in his own business looked upon it not as a luxury but as a necessity of life, and the same thing which had operated on his mind was operating on the minds of others. The colony had been suffering for the last three or four years from excessive droughts, which had had a very prejudicial effect on the general interests of the colony. But this state of things was not going to last for ever. He thought that £15,000 in a few years time would not be considered of great moment considering the enormous advantages which were daily experienced from the cable. The cable, he believed, would never have been laid but for Cetewayo; but he believed that in selecting the eastern coast the selection was made hastily, at a time of great public emergency. It had already, however, been of infinite importance in our political troubles. It had staved off wars and prevented enormous mischiefs by bringing the Colonial Government into direct communication with the Imperial Government in Downing-street. They had dealt with political and commercial interests; but there were also private interests to be considered, and he knew of cases where the cable had become a regular medium of communication and where the greatest inconvenience was experienced whenever a breakage occurred.

Mr. R. J. JENKINS thought after what Captain Mills had said as to the advantages of an alternate route that the question really turned on the raising of the capital. He had some knowledge of cable work, and he could say with every confidence that if the subject were approached now with the manufacturers (of whom there were some half a dozen in this country and some abroad), people would find a very different figure would be asked for the manufacture of a cable. All experience in that line had been bought, and bought very expensively, as the Chairman had said, by the British public. If the matter were taken up in a public manner, and the Imperial and Colonial Governments took up the matter with sufficient spirit, there was public spirit here enough to provide an alternative communication. He had no doubt that the Eastern Company and Sir James Anderson were perfectly honest in saying that the interests of the Company and the public were one. Up to a point they were, but there was a point where the union of interests would cease. Sir James Anderson had stated that the line did not pay; but how could it be expected when it was a considerable time not working? He was satisfied that an alternate route was one that should commend itself rather than duplication, because he believed that duplication would come as a matter of fact.

The CHAIRMAN, in reply, said with regard to the resolution, it was simply limited to a protest as to the way the cable had been working. The question of the route would be the subject of the second resolution. He then put the motion, which was carried, and said that it would be communicated to Sir James Anderson. In respect of the second resolution he observed that it was a declaration that a second cable was necessary, and that it should be laid down, in the opinion of the meeting, *vid* the West Coast. When he had used the word "competitive," he had meant an alternative line. He was delighted that Captain Mills was of his opinion. As to the question of subsidy, he did not think any cause was advanced by want of candour, and his own impression was that without a subvention a line along the West Coast could not pay, and consequently he would not harbour himself under the doubt which Captain Mills had expressed as to whether it would or would not pay, but say at once that it would not pay, and that therefore a subvention was necessary. With great submission, however, to Captain Mills's knowledge of the Cape Government, and with great deference to the opinion expressed by that gentleman, he would venture rather to think with Mr. Silverbauer that if it were a question not of £15,000 but of £50,000, so that the Cape Government and the dependencies could have the proposed additional communication, he thought there would not be any difficulty in getting it, and he believed that the Germans, in view of their new colony, would assist. He regarded the necessity of cable communication now as being as great a necessity as gas or any other daily requirement. It was an absolute necessity, because once they had laid out their arrangements for communication the mere cessation of a week or ten days caused a complete break in the communications. The duplication of the cable along the East Coast was a very proper precaution, but it was not an absolute guarantee, and that was what they wanted as far as possible—an absolute guarantee that they would never get up any morning and find communication 7,000 miles away absolutely stopped for an indefinite period. Therefore, he held, they must go to the West Coast. The question, however, was how far they should make that statement in the City of London without endeavouring to do something practical. His impression was that with the trade on the West Coast, with the subvention which could be obtained from the Imperial Government, and, with great respect to Captain Mills's opinion, from the Cape Colony, and possibly from some of the interior Governments, there would be no difficulty in the matter. As Mr. Jenkins had pointed out now, when cables were at such a very low price, was a favourable opportunity for laying a new cable, which, with a moderate traffic and a subvention, ought to give a moderate return with a very low tariff. He therefore commended the next resolution to their attention. It was as follows:—"That the constant breakages of the cable on the East Coast of Africa involve great interruptions, which are prejudicial to the mercantile community having relations with South Africa, and demand a remedy; and this meeting is of opinion that a second line, *vid* the West Coast of Africa, is imperatively required."

Mr. JENKINS seconded the motion.

Captain MILLS said he had to leave the meeting to fill another engagement, but before going, he desired to say that, in alluding to a subsidy from the Cape Government, he had merely expressed his own opinion, taking care particularly also to mention that he had no instructions from the Government.

The CHAIRMAN put the motion, which was carried. The third resolution would be taking, he said, a practical step towards carrying out the resolution just passed. It was as follows:—"That a memorial embodying the views of this meeting be presented to the Right Honourable the Earl of Derby, Secretary of State for the Colonies, such memorial to be signed by the representatives of the firms interested in the West and East Coasts of South Africa; and those present pledge themselves to use their influence to obtain the end desired."

This resolution was also carried.

The CHAIRMAN afterwards read the memorial, one clause of which was as follows:—"We are of opinion that the great interests represented in South Africa demand a second cable; and, seeing that the British merchants on the West Coast have no means of cable communication, this meeting is of opinion that a second line should be laid down to communicate by the way of the West Coast either from the Cape to Lisbon or to join the Brazilian line at Cape Verde, or such other station as may be found most convenient." In signing this memorial, continued the Chairman, they were committing themselves to nothing beyond putting in writing the opinions they had expressed in the resolutions which they had passed.

A vote of thanks to the Chairman brought the proceedings to a close.

COMPANIES' MEETINGS & REPORTS.

Reuter's Telegram Company (Limited).

The twenty-first ordinary general meeting of the shareholders of this Company was held at the Company's offices, 24, Old Jewry, on Wednesday last, Colonel James Holland presiding.

The SECRETARY having read the notice convening the meeting,

The CHAIRMAN said: As described in our report in the second paragraph, the falling off in the receipts and the net profits as compared with last year is entirely owing to the military operations in China, Egypt, and the Soudan, and especially the latter, for these districts being beyond the course of our regular correspondents we have been compelled to employ special correspondents, and in a service like that in the Soudan and in Egypt it will strike you naturally that it is a service which requires high payment. Great risks are run, and as an evidence of that I may mention that one of our correspondents perished and another was very severely wounded. We have been greatly indebted to the gentlemen who have been and still are our correspondents in those districts for the zeal and the highly satisfactory manner in which they have performed their arduous and perilous duties. But those services, although they tend to keep up our reputation, which is a matter of the first importance to us as a Company formed for the procuring and dissemination of important news, has proved, unfortunately, as might have been expected, anything but beneficial to the shareholders—that is to say, the expenses have increased to a greater extent than the receipts. If you turn to the balance-sheet you will find that the receipts have been £3,700 more than they were last year, which shows at any rate that the business is not falling off. But, on the other hand, the cost of procuring the intelligence has increased by just under £6,000. It will be, therefore, a serious and anxious duty for us as the engagements now standing with the press fall in—as they expire—to endeavour with such fresh agreements as will satisfy the shareholders that a very moderate interest that we look for upon our capital should be made in the future. It is evident that with wars constantly on the horizon expenses must increase beyond the receipts, unless those receipts are augmented, and the outlook is not at all a reassuring one at the present time. Turning to the balance-sheet, there is very little beyond the fact which I have mentioned of increased receipts and increased expenses to note. The liabilities and debtors' accounts are mere current accounts that are settled at the end of every month, and there is nothing whatever to say about them except that the liabilities which existed on the 1st of January no longer exist, and it is so far satisfactory that we may say that we have no bad debts. The current expenses have increased in sympathy with the general expenses of telegrams and agencies. Having increased work to do we have had an increased staff to maintain at home, and there is an item also of about £600, which is not likely to occur again, in increasing the accommodation in the present building. There is really nothing further to say, except to express a hope that when we meet this time next year, as I trust we all may, we shall find that, although the war expenses may still continue, yet that those who benefit by our exertions will be able to show a more complete appreciation of the benefits they receive from us than they have done in the past. With these remarks I have nothing more to do than to propose "That the report and balance-sheet now presented be received and adopted, and entered on the minutes."

Admiral the Right Hon. Sir JOHN HAY, M.P., seconded the motion.

The CHAIRMAN invited discussion, but no one rising to address the meeting, he put the resolution, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. J. S. STOPFORD, Baron de Reuter was re-elected to his seat at the Board.

The auditors, Messrs. Quilter, Ball, and Company, were afterwards re-elected.

Mr. LOVEDAY then proposed a vote of thanks to the Chairman and Directors, the Secretary and staff, observing that he did not think there

Digitized by Google

could be a more powerful evidence of the confidence of the shareholders than the paucity of their attendance at that meeting.

The motion having been put and carried, the CHAIRMAN briefly acknowleged the vote, and the proceedings terminated.

The Eastern Extension, Australasia, and China Telegraph Company (Limited).

Report of the Directors for the six months ended 31st December, 1884, to be presented to the shareholders at the twenty-third ordinary general meeting, to be held at the City Terminus Hotel, Cannon-street, on Wednesday, the 29th inst., at 2 o'clock.

The gross receipts, inclusive of Government subsidies, have amounted during that period to £248,087 19s. 5d., against £231,056 1s. 4d. for the corresponding half year of 1883, showing an increase of £17,031 18s. 1d. The working and other expenses, including the abnormally heavy item of £33,746 10s. 1d. for cost of repairs and renewals of cables and expenses of ships, absorb £79,496 9s. 1d. against £69,862 0s. 2d. for the corresponding half year of 1883, leaving a balance of £168,591 10s. 4d. From this is deducted £2,767 13s. 5d. for income tax, and £41,595 for interest on debentures and contributions to sinking funds, leaving £124,228 16s. 11d. as the net profit for the half year, which, with £17,147 18s. 1d. brought forward from the previous half year, leaves an available balance of £141,376 15s. Against this the Directors have charged £20,000 on account of the partial renewal of the Singapore-Saigon and Penang-Rangoon cables. One quarterly interim dividend of 1½ per cent., amounting to £31,250, has been paid for the half year, and it is now proposed to distribute another of like amount, together with a bonus of 2s. per share, payable on the 30th instant, making with the interim dividends and bonus paid for the first half year a total distribution of 7 per cent. for the year 1884. The balance of £33,876 15s. has been carried to the general reserve fund, which now stands at £510,649 11s. 9d. The investments on account of this fund now include the securities shown in former accounts as standing in the names of the trustees of the 5 per cent. Australian subsidy debentures, the same having been sold to the Company to provide funds to meet the bonds drawn for payment on the 1st July last. In pursuance of the conditions upon which the issue was made, 433 of the Company's 5 per cent. debentures of 1880 were drawn by lot on the 18th instant for payment at par on the 1st May next. A new cable steamer, "Magneta," built for the Company by Messrs. R. Napier and Sons, was despatched on the 8th ultimo to Singapore to replace the ss. "Agnes," which had been ordered home to be overhauled with a view to the repairs reported to be necessary. No tidings of the ship's arrival at Gibraltar having been received up to the present time, the Directors are reluctantly compelled to infer that unhappily she has been lost with all hands. The ship was fully insured. The policy of strengthening the weak portions of the Company's system has been continued during the half year by the renewal with brass-ribboned cable of 285 nautical miles of the Singapore-Saigon Section and 100 nautical miles of the Penang-Rangoon Section. Most of the old cable will, it is anticipated, be picked up and brought into the spare stock of cable at Singapore during the current half year, when the cost of the operation will be shown in the accounts. The cable when re-served will be available for further renewals or extensions. The principal cable interruptions during the half year have occurred on the Penang-Madras and Java-Australian (original) Sections. The former took place on the 13th June, during the height of the south-west monsoon, but was successfully repaired during a lull on the 14th July. Unfortunately, however, the large expenditure of cable shown in Abstract C was principally incurred during this repair in consequence of a return of bad weather immediately after restoration of the communication preventing the recovery of the old cable, which, however, may be picked up when a favourable opportunity offers. The cable between Victoria and Tasmania was also interrupted in July, and owing to the unusually severe weather that prevailed at the time, was not repaired until the end of September. To prevent as far as possible a recurrence of the inconvenience to the Colonies and loss to the Company thus occasioned, the Directors have determined to duplicate this section (176 knots in length) from its stock of spare cable at Singapore. All the Company's cables are now in good working order. During the past half year the land line belonging to the South Australian Government between Port Darwin and Adelaide has continued to work well. In accordance with the Articles of Association, Charles William Earle, Esq., and Sir Thomas Fairbairn, Bart., retire by rotation, and offer themselves for re-election. The retiring auditors, Mr. Henry Dever and Messrs. Quilter, Ball, and Co. offer themselves for re-election.

The Oriental Telephone Company (Limited).

Report of the Directors for the year ended 31st December, 1884, to be presented to the shareholders at the Fifth Ordinary General Meeting at the City Terminus Hotel, Cannon-street, on the 28th inst., at one o'clock :—

The profit and loss account, so far as the year's operations are concerned, results in a credit of £3,242 19s. 9d., after including the dividends accrued on shares held in the subsidiary companies. It has been deemed advisable to charge this account with the full liabilities incurred in respect of guarantees to the Bombay and Bengal Companies, and the amount of £9,082 6s. 7d., now appearing to debit, represents the guarantees to 31st December last. The foregoing sum embraces, in the case of the Bombay Company, a period of 18 months from the 1st July, 1883, and in the case of the Bengal Company of 19 months, from 1st June of the same year. A further important item charged to this account is the difference between the nominal market value at the end of the year of the "A" shares held in the Bengal Telephone Company, and the price at which they were valued in the balance sheet for 1883. Against these sums debited as above, the following items have been transferred from the balance sheet of last year to the credit of profit and loss account :—£7,000 entered as a reserve fund, £8,426 0s. 5d. profit on sale of the Bengal Exchange, and a further sum of £1,000, being one-half of the amount, reserved last year in respect of estimated depreciation of the Egyptian Indemnity Award. The indemnity award amounts to 200,000 francs, which will, it is hoped, be received very shortly, and so strengthen the available funds of the Company. The balance remaining at credit of profit and loss is £3,945 1s. 1d., which it is proposed to carry forward to meet current guarantees and possible further depreciation of assets. No new exchanges were opened in the year under review, but one is in course of construction at Moulmein, to which considerable support has been promised, and it is anticipated a small income will be derived therefrom during the current year. The opposition which has existed in Calcutta has been removed. This, we trust, will greatly benefit the Bengal Company. There has been a fair increase in the number of subscribers, to both that and the Bombay Company's exchanges, during the year. The Telephone Company of Egypt has added ninety to its number of subscribers, and the shares held in that Company have been taken into account at the same valuation as last year. From Shanghai the accounts received from the agent are very promising in spite of the unsettled state of China. The books of the China and Japan Company have not yet been made up, the final accounts not having been received. As the shareholders have so recently had placed before them the report of the committee of investigation, the Directors do not think it necessary to make any further statement regarding the affairs of the Company. The call of one shilling per share made payable on the 10th ult. has been received to the extent of £9,600, leaving £1,400 still due. The loan of £5,000 from the bankers has been paid off. The Hon. G. G. Hubbard, Mr. T. A. Edison, and Mr. P. Carnegy, C.I.E., retire from the direction. Messrs. Deloitte, Dever, Griffiths and Co., the auditors of the Company, retire, but offer themselves for re-election.

NOTES.

THE SION COLLEGE.—It is proposed to light the new Sion College by electricity.

THE TELEGRAPH TO MERV.—The *Daily News* says:—"The telegraph line to Askabad and Merv is advancing!"

THE SUBMARINE TELEGRAPH CABLES BILL.—This Bill passed through its second reading on Monday night.

ELECTRICITY AND SUBMARINE MINES.—Experiments are about to be made at St. Petersburg with submarine electric lamps.

THE CABLE IN THE CASPIAN SEA.—A telegram from Vienna announces that this cable was cut, on Monday last, by some fishermen.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 24th April amounted to £3,151.

SMART.—The result of the Oxford and Cambridge boat race was received in the office of the New York *Telegram* exactly five seconds after the finish.

NEW CABLE.—The new cable between the Isle of Man and Cumberland has been successfully laid, and telegraphic communication was resumed on Saturday evening.

OVERHEAD WIRES.—A letter, asking the Southend Local Board to petition Parliament against the United Telephone Company Bill, has been referred to the Parliamentary Committee.

THE STANDARD OHM.—We notice in the advertisement columns of a contemporary that a few of these are to be had at 2s. 6d. each. See into what disrepute the unfortunate unit is falling!

THE HONG KONG CABLE.—The Colonial Government has at last recommended the furnishing of the cable and torpedo boats which have been pressed for in *The Times* for some months past.

NEW TELEGRAPH COMPANY.—A company has been organised in Topeka, Kansas, for the immediate construction of a new line of telegraph from Kansas City to California, to be known as the Western Telegraph Company.

THE EASTERN TELEGRAPH COMPANY.—This company announce the payment, by interest warrant, on the 1st May proximo, of interest for the half year ending 30th April on their Four per Cent. Mortgage Debenture Stock.

THE ELECTRIC LIGHT IN RUSSIA.—That the workmen employed by the Russian Steam Navigation Company may work at night, electric light plant of the value of £3,000 has been provided for the illumination of the yards.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 24th April were £2,515, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

OPENING OF NEW TELEGRAPH STATIONS IN CHINA.—The Eastern Telegraph Company notifies the opening of three new telegraph stations in China, one on the island of Hainan, called Kiungchow or Hainan, and the others at Liemchow and Neuchang.

THE TELEPHONE WANTED AT BLACKBURN.—Tenders are invited for the erection and maintenance of about 19 miles of telephonic wire, together with the apparatus for working it, at Blackburn. Full particulars will be found in our advertisement columns.

THE ELECTRIC LIGHT ON WARSHIPS.—Messrs. R. E. Crompton and Co. have secured orders for lighting five of Her Majesty's ships. We are informed that this company have orders on their books for dynamos to give a total output of nearly one million watts.

CHEAP TELEPHONES.—On reference to our advertisement columns it will be seen that the Signal Engineering Company are supplying improved telephone receivers, in ebonite cases, at a price which will place these very useful instruments within the reach of everyone.

THE "MAGNETA."—Several bodies have been washed ashore on the Portuguese coast; but up to the time of going to press none have been recognised as belonging to the crew of the missing ship. Instructions have been sent to spare no effort to identify any bodies thus washed ashore.

THE DIRECT UNITED STATES CABLE COMPANY.—The directors of this company have resolved upon the payment of an interim dividend of 3s. per share, being at the rate of 3 per cent. per annum for the quarter ending 31st March, such dividend to be payable on and after 16th inst.

THE ELECTRIC LIGHT AT THE HOUSE OF COMMONS.—The success which has attended the introduction of the electric light in other parts of the House of Commons buildings has induced the First Commissioner of Works to extend this system of illumination to the members' tea room.

THE SOUDAN TELEGRAPH LINE.—On Tuesday morning a party of Hadendowas, probably assisted by some Egyptian convicts who had escaped to Osman Digna, cut the telegraph wires, pulled down several of the poles, and undermined the metals on the railway in several places between Handoub and Suakin.

BATHING IN LIGHTNING.—The *New York Mail* says it is hard to conceive a more risky thing, for example, than some of the electric baths, where the visitor, being shut up in a pen, is entirely at the mercy of an attendant, who may turn on enough electricity to send him to death before he is aware of it.

IMPROVED WHEATSTONE TRANSMITTERS.—The Post Office are now issuing a new form of automatic transmitter capable of running at a speed representing 400 words per minute, 10ft. of paper passing through the instrument in 7½ seconds. The top speed of the old form of transmitter was 200 words a minute.

CHARING-CROSS AND WATERLOO ELECTRIC RAILWAY.—The Bill for extending the Charing-cross and Waterloo Electric Railway from Northumberland-avenue to Cockspur-street has been withdrawn. The Bill was one of a group set down for hearing before Mr. Hardcastle's committee of the House of Commons on Monday.

TELEGRAMS FOR EAST AFRICA.—The Eastern and South African Telegraph Company notifies that the steamer specially engaged to carry telegrams will leave Zanzibar early on Saturday for Mozambique. Telegrams for South Africa to go by this vessel should be sent from London not later than eight o'clock on Friday evening.

THE TELEGRAPH IN CHINA.—The war between the French and the Chinese has, it is said, had the effect of inducing the authorities of the Chinese Empire to extend their telegraph system. The principal towns on the frontier of Yunnam have been connected to Canton by improvised lines, constructed in many cases through dense forests.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—At a meeting of the directors of this company held on 29th April, it was decided to place £8,000 to reserve, and to recommend to the shareholders at the approaching meeting

Digitized by Google

that a dividend of 6s. per share be declared on account of arrears of dividend on the first preference shares.

OVERHEAD WIRES IN AMERICA.—A discussion is going on at Harrisburg, Pa., on a Bill to place electric wires underground. Representatives of the Western Union and Pennsylvania Electric Light Company have been heard against the Bill. The legislative committee in charge of the measure has decided to limit its operations to cities of the first and second class, which are Philadelphia and Pittsburg.

THE ELECTRIC LIGHT IN CANADA.—We are informed that Messrs. Francis and Co., of the Eagle Telegraph Works, Hatton-garden, E.C., have obtained a contract for the complete installation of electric lighting throughout the New Congress Hotel and avenue at Toronto, together with electric bells and indicators to and from each apartment of the several buildings, and direct telephonic communication between the hotel and the Dominion telegraph stations.

THE ELECTRIC LIGHT IN NEW ORLEANS.—New Orleans has been for a good while debating the lighting of the suburban districts. Finally an ordinance was passed by the City Council, and signed by the Mayor, awarding the contract for tower lights to the Louisiana Electric Light Company. On 17th March the Council decided that 34 tower lights should be furnished at an annual cost of $34,000, with the proviso that the city should be at liberty at any time to increase or decrease the number of lights.

THE ELECTRIC LIGHTING IN VIENNA.—The Imperial and Continental Gas Association who, as already notified in our columns, have obtained a concession for lighting Vienna, have entrusted Messrs. R. E. Crompton and Co. with the contract for supplying the requisite machinery, which will include, among other things, three of the largest dynamos, each capable of developing 100,000 watts at terminals. These machines will be driven direct by Willans' latest form of compound engine. Electro governors will also be used in this installation.

THE B.T.K. SYSTEM.—The Consolidated Electric Company has installed 108 of their No. 2 B.T.K. accumulators in the Quadrant of the International Inventions Exhibition, the coloured incandescent lamps on the tables and in the reception room at the dinner of the Civil Engineers on the 29th ult., having been run from 82 of these cells. A very successful installation of the B.T.K. system has also been completed this week at the residence of S. Courtauld, Esq., Bocking-place, Braintree, where 64 incandescent lamps have been fitted, supplied from accumulators.

DOMESTIC ELECTRIC LIGHTING.—A temporary installation of electric light was made at Lady Hervey's, Hyde Park Place, on Thursday last, on the occasion of her ball. The work was carried out by the Electrical Power Storage Company for and under the direction of Mr. F. Geere Howard, of 36, Cleveland-street, Fitzroy-square. Twenty-four lamps of 20 candle-power were used, fed by 24 one horse-power, E.P.S. accumulator cells placed in the area. These cells were brought from Millwall the same afternoon and returned the next morning. The lights were on 6½ hours.

BOOKS RECEIVED.—"The International Inventions Exhibition Railway Guide and Route Book," compiled and edited by J. R. Somers Vine, official agent of the Exhibition at the City offices, 96, London-wall, E.C., contains, besides a number of compendious time tables, &c., some useful and interesting notes for visitors.—The Specialist Series. Vol. III.: "Ballooning; a Concise Sketch of its History and Principles." By G. May. London: Symons and Co., 27, Bouverie-street, E.C.—"Proceedings of the National Conference of Electricians, Philadelphia, September, 1884." Published by W. J. Johnston, New York.

EXTENSION OF TELEGRAPHS IN CANADA.—The new telegraph line around the north Canadian shore of Lake Superior is now said to be in excellent working order, thus giving direct telegraphic connection through Canada, by the Canadian Pacific Railway route, without passing through United States territory. The train despatcher's office at Ottawa has now direct connection with the train despatcher's office at Winnipeg, with only one circuit. The distance is 1,400 miles, and messages have been sent and received with accuracy. At an early date direct connection will be completed between Montreal and the Rocky Mountains.

AN IMPORTANT EXPERIMENT.—On the occasion of a recent execution in Paris, the professors of the school of medicine were so anxious not to lose time that they went to the cemetery and began their work directly the body was replaced in the prison cart. It is pretended that the results of this examination, effected at the short interval of thirty-five minutes after decapitation, and which had especial reference to the effects on the motor regions of the cerebral substance on their being stimulated by electricity, are of extreme importance. It was ascertained that on the brain being directly subjected to excitement by electricity a movement was produced of the facial muscles.

L'ECOLE CENTRALE DES ARTS ET MANUFACTURES, PARIS.—The new school buildings erected in Paris are of an extensive character, having a frontage of 99·6 metres, and a depth of 60·9 metres. The basement contains, among other things, three large Geneste and Herscher generators for heat and ventilation, the boilers of which also serve the engines used for the generation of electricity for purposes of illumination. The electrical works of the school are said to be very remarkable. They include two engines, each of 40 horse-power, working an Edison dynamo of 200 lamps, and three Gramme machines, which latter are used alternately to actuate six ventilators, distributed over the building. The offices of the administrative body and a large amphitheatre on each story are lighted both by gas and electricity.

THE CABLE IN THE ARLBERG TUNNEL.—It is proposed to lay a gigantic telegraph cable, of a length of 10,270 metres, and weighing nearly 80,000 kilogrammes, in the tunnel of the Arlberg in Austria, inaugurated on the 15th of last August. The cable is composed of twelve conductors, of which six are reserved for the special service of the State, three to that of the railway, while the three others will be spare. Each conductor in itself consists of seven wires of copper twisted and embedded in gutta percha. Besides the insulating material and the usual serving, the cable will be wound with metallic tape, and finally bound with eighteen galvanised iron wires. It is further protected at its two extremities, *i.e.*, Saint-Antoine in the Tyrol on one side, and at Langen on the other, by two lightning conductors of large size.

THE AMEER AND THE TELEGRAPH.—The correspondent of the *Daily News* at Rawul Pindi states that among the Ameer's presents which he takes with him from India are four sets of telephones; and that it is thought possible he will consent to a line of telegraph being laid from Jamrud to his capital. This would be a great gain, as it is highly important in these critical times that we should have rapid communication with Cabul. If we could, too, get a telegraph line from Herat through Candahar to Chaman, it would be of immense benefit to us, as news now takes a fortnight to reach us, except through Mashhad, Teheran, and the Persian Gulf, which line

Digitized by Google

is a precarious one, and would be instantly closed—or at least the section from Mashhad to Teheran—if Russian influence became paramount at the Court of the Shah, for that section belongs solely to the Persian Government.

ELECTROTYPING.—The electric machine used by the Electro-Metallurgical Company is the Elmore dynamo, which has the power of depositing one and a half tons of copper in one week, and this the finest and purest metal that can be found. The copper is deposited in tanks holding upwards of sixty thousand gallons of solution, the largest tanks being 15ft. deep by 10ft. by 12ft. in length. These large tanks are used for coating large pieces of machinery with copper, such as the rams for the recoil machinery of the big guns on board Her Majesty's ships of war, which, if not copper coated, would soon be destroyed and oxidised by sea water. A coating of as much as half an inch in thickness is laid upon these. They range from 6ft. to 10ft. in length, and are from 6in. to 18in. in diameter, but the plant is arranged to coat rams up to 24in. in diameter. An ingenious system of overhead travellers enables these heavy pieces to be suspended in the tanks, and moved about with great facility.

CHINA, DENMARK, AND THE GREAT NORTHERN TELEGRAPH COMPANY.—With reference to the conspicuous anxiety of Denmark to give a proof of her friendship for France at the expense of China in regard to the declaration of the former that rice is a contraband of war, the *Pall Mall Gazette* states that Denmark's conduct has caused the utmost surprise and annoyance among Chinese officials, who remember the extraordinary concessions which China granted to Denmark some years ago in the form of the telegraphic convention entered into between Li Hung Chang and the Great Northern Telegraph Company. It is regarded as strange that the Danish Minister of Foreign Affairs should have forgotten, when he promptly sacrificed China to France, that this convention is not yet ratified, and that the political insignificance of Denmark, which was so powerful a reason for granting to her these extraordinary concessions, may perhaps now appear to the Chinese the very reason why they ought not to have made them.

THE PHŒNIX ELECTRIC LIGHT COMPANY.—One of the numerous cases involving alleged fraudulent representation in the prospectus of new companies came before Mr. Justice Chitty on Tuesday afternoon. Mr. Dawson, an applicant for shares in the Phœnix Electric Light Company, now in course of liquidation, who on application paid his deposit of £50 on 500 shares and afterwards a first call, brought his action against the company on the ground of misrepresentation contained in the prospectus, on the faith of which he applied for shares. The prospectus, of course, contained a glowing vision of future profits to be derived from the working of Fitz Gerald's patents, already spoken highly of by Prof. Varley, for which offers had been made. The plaintiff alleged that the persons who made the offers to the company were people of no means, and that Prof. Varley's certificate was qualified by the expression that he had not had the opportunity of submitting the invention to a test of long duration. The case is likely to last for some time.

"IS THERE A TELEGRAPH TO MERV?"—The following additional particulars and corrections relating to our leading article under this title last Saturday have reached us from various sources since then. The railway to Askabad is certainly completed, General Zelensy having mentioned it as a well-known fact in his recent address to the Tiflis Geographical Society. The telegraph poles in that locality are uniformly of iron, a circumstance which disposes of M. Lessar's difficulties in respect to the local scarcity of timber. As to news by courier, O'Donovan's ride from Teheran to Shahrood, a distance of 284 miles, in 1880, was performed in two days and three-quarters, counting only from sunrise to sunset, changing horses at the post houses every 24 or 32 miles. We find that we understated our case as regards the distance of Tirpul from Meshed. It is twice that which separates Ak Tapa from Sarrakhs. Lastly, General Komaroff now admits that he received the order prohibiting the occupation of Penj-deh on 23rd March—only six days after the date of the "solemn convention."

THE ELECTRIC LIGHT AT BELLEGARDE-SUR-VALSERINE (AIN).—For very nearly a year this pretty little town has possessed an electric lighting system which will compare most favourably with that of much larger centres of population. The works are situated by the railway line from Mâcon to Geneva, upon the picturesque Valserine River, where a waterfall is utilised to furnish an available force of about 2,000 horse-power. The dynamo, which is a Thury multipolar machine, has been constructed by Messrs. Meuron and Cuenod, of Geneva. The subscribers, who are rapidly increasing in number, are able by a wise arrangement to pay for the light by the lamp, by the hour, or by the month, at the following prices:—

One 8-candle lamp.....	0·4d. per hour
One 16-candle lamp	0·8d. „
Subscription per month	2s. 4d. per 8 candles
Or	4s. 8d. „ 16 „

The lamps used are the Edison incandescent, of which a large number, of 16 candle-power, are used in the lighting of the streets.

HEATING TRAINS BY ELECTRICITY.—In the system of MM. Courcelles and Elu, heat is produced by the passage of the current through a certain number of small lead plates contained in a footwarmer, &c., of the ordinary pattern. These plates of lead are placed according to the length of the footwarmer, and are all in derivation upon two conductors of iron wire, which carry the current. In such case the heat is found to be distributed in a uniform manner. In some experiments with the current produced by a Gramme machine traversing in series five footwarmers, of which the dimensions were 0m·22 long and 0m·05 thick and 1m·80 length, each case containing 45 plates of lead, the five cases are found to be sufficient for the heating of one carriage. The current was 24 amperes, with a difference of potential of 50 volts at the terminals, and the energy dispensed was 120 kilogrammetres, or more than a horse-power and a half. From these figures it may be seen that with a train composed of several carriages this mode of heating requires a considerable amount of power, and the adoption of such a system would entail an expense which few railway companies will probably be disposed to incur.

DECOMPOSITION OF SOUND.—*L'Etoile Belge* says the celebrated physician, Logosphillos, of Athens, has by means of an apparatus resembling the telephone been able to decompose the sounds emitted by the human voice. The apparatus comprises a receiver, consisting of a very thin metallic plate, of large dimensions, connected to a multiplicity of metallic wires, of unequal length and thickness and all communicating with a dynamo machine, also connected to the receiving plate. This plate is immersed in a bath of distilled water, having the form of a prism. It is said (says our Belgian contemporary) that a prism of glass, or of water, has the faculty of decomposing light. It is proved to-day that light, heat, electricity, sound, &c., are similar forces. The photophone has demonstrated that truth, and now we are told that a prism of water de-

Digitized by Google

composes the voice, and that each oscillation or vibration is transmitted, according to its intensity, to a special cord. The appearance of the arrangement of these metallic cords resembles that of a harp. It is dreadful to imagine what would be the result if one omitted to place *distilled* water in the apparatus of M. Logosphillos. The soft notes of one of our queens of song might by such inadvertence be reproduced in the less agreeable tones of our native Billingsgate.

THE NATIONAL TELEPHONE COMPANY.—The April list of subscribers in the Scottish North Eastern District of this company has just been issued. This list includes the counties of Aberdeen, Banff, and Kincardine, and shows that, although the first telephone was not placed in Aberdeen until 1881, there are now in operation nearly 450 instruments, a number of exchange connections, including switch lines, amounting to 425, and 29 private lines, representing together a length of nearly 260 miles of wire in the district. The longest line is that to Culter Paper Mills, which measures eight miles 447 yards. The longest private line is that of Messrs. Mitchell and Rae, from Ellon to Newburgh, five miles 870 yards. In other districts the company have much longer lines in operation, notably between Glasgow and Edinburgh, and Glasgow and Greenock. New call offices have been established at the National Telephone Company, 28, Market-street; the National Telephone Company, Arches, Wellington-road; Ellis and M'Hardy, 132, Union-street; Wm. Bain, 44, Union-place, for the use of subscribers and the general public. Non-subscribers can speak to subscribers (within a radius of six miles) from these offices only, on affixing telephone stamps to the value of 3d. for three minutes' conversation, and 1d. for each additional minute, to the call office sheet. Telephone stamps are sold at the call offices.

NEW ARRANGEMENT OF THE THERMO-ELECTRIC PILE OF MM. CLAMON AND CARPENTIER.—At a meeting of the Academie des Sciences on the 13th of April last some new models of thermo-electric piles of an improved nature were presented. The couples of these new models are of plates of iron or of nickel, and of bars of an alloy of antimony-zinc. That alloy is said to give its maximum of thermo-electric power when the two metals are mixed according to their equivalents, feeble variations in their proportions being productive of large variations in the energy of the couples. Each couple attains its maximum of electromotive force at the temperature of the fusion. This maximum is $\frac{1}{10}$ of a volt for the couples of iron alloy, and about $\frac{1}{8}$ for the couples of nickel alloy. To counteract the dangers to which the pile is exposed, when the temperature arrives at this limit the heating is arranged to maintain a sensibly lower temperature; the electromotive force utilised is then reduced to $\frac{1}{11}$ of a volt for iron alloy and $\frac{1}{12}$ for nickel alloy. Of two models which were shown one was comprised of 12 sets of 10 elements, giving altogether 120 elements. The normal electromotive force was 8 volts and the resistance 3·2 ohms. The other had 6 sets of 10 elements, giving 3·6 volts, and having a resistance of 0·65 ohm. The quantity of gas consumed per hour was the same for the two models, and amounted to 180 litres.

THE TELEPHONE COMPANY OF IRELAND.—The directors, in their report for the six months ending 31st December, say the increase in the number of wires, both exchange and private, erected during the year, and of orders received, has again been very satisfactory, the total number being 809 on 31st December, 1884, as against 647 on 31st December, 1883. The directors are in communication with the Post Office Department with a view to obtain the consent of the Postmaster-General to establish public telephone call offices at all the post offices in Dublin and the suburbs. This arrangement has been found to be most convenient by the public in Paris, where the requisite license was readily granted to the Local Telephone Company by the French Minister of Posts and Telegraphs. The line to Kingstown is opened, and working satisfactorily. It is intended to establish a public call office here, and a considerable extension of business is anticipated in this direction. The amount standing to the credit of profit and loss, including the balance of £99 10s. 3d. brought forward from last account, amounts to £1,369 0s. 8d. This admits of payment to preference shareholders of the full dividend, amounting to £550 12s. 5d., upon the preference shares. The balance, £818 8s. 3d., admits of a dividend at the rate of three-quarters per cent. per annum upon the ordinary shares, as against one-half per cent. per annum for the corresponding period of last year, leaving £162 3s. 3d. to be carried forward to the credit of the current half year.

LIGHTING OF THE ULSTER HALL, BELFAST.—On the occasion of the visit of the Prince and Princess of Wales, the ball room, vestibule, staircases, corridors, and supper rooms of the Ulster Hall, as mentioned in our last issue, were brilliantly lighted throughout by electricity. The lighting of the ball room consisted of a range of about 200 glow lamps fixed under the balcony which surrounds three sides of the hall, and screened by a draping of pink tarlatan. Six powerful arc lamps hung from the ceiling, enclosed in thick opal shades, and were further toned down with yellow and pink muslin, which transformed the ordinary somewhat trying effect of arc lighting into a tempered radiance, which it was admitted gave a most becoming effect. A novel and striking feature was a miniature iceberg, surrounded by rare exotics, and illuminated from the interior by variously coloured incandescent lamps, giving a wonderful effect, as of enormous blocks of ruby, emerald, and opal. The vestibule was also lighted by glow lamps, the central gasalier being used for one cluster, while a number of handsome brackets, with cut glass shades, surrounded the walls. Underneath the staircases were ice grottoes and ferneries, studded with incandescent lamps; and, ascending the stairs on either side, the landings were transformed into "cool grot and mossy cell," the realism of which was enhanced by falls and jets of water lighted by glow lamps in frosted bulbs, some being completely submerged, to the great bewilderment of the gold fish which flashed about in the light. In the long corridors the glow lamps again appeared in a new guise, being hung under glass shades of novel and artistic shape. The supper room was lit entirely from the roof by some 200 glow lamps in clusters of three under white reflectors, which harmonised well with the floral and general decorations of the room. In the Princess's boudoir and the Prince's room electricity was still the illuminant, cut crystal brackets being used in the former, while in the latter the lamps were concealed in the interstices of the rockery and foliage. It is satisfactory to note that Belfast is far enough advanced to be able to provide so complete an installation of electric lighting from the resources of a local company, the entire work being done by the Belfast Electric Appliances Company, whose able manager, Mr. G. Annesley Grindle, deserves every credit for the perfection of his arrangements and the complete success which attended this application of electric lighting on so extended and varied a scale to ball room decoration. It may be observed that, notwithstanding the total absence of any arrangements for ventilating the hall, the temperature throughout the evening was so pleasant as to call for universal remark, and to receive the special commendation of His Royal Highness. The power for lighting was supplied by the engine at the company's works, supplemented by a semi

Digitized by Google

portable compound engine, kindly lent by Messrs. Fowler and Co., of Leeds, and by a special lighting plant of Messrs. Ewart and Co., which was kindly placed at the disposal of the company. The glow lamps (90 volt Victoria Brush) were run by Elwell-Parker 12-unit dynamo machines, and the arc lamps were the Belfast arcs, manufactured by the local company.

ELECTRIC LIGHTING IN BRADFORD.—A Bradford contemporary says:—That the usefulness of electricity for lighting purposes is gradually becoming more appreciated in Bradford is proved by several extensive installations which have recently been made. Messrs. John Roper and Co., of Trafalgar-street, have just completed the fitting up with apparatus for electric lighting of the rooms on the ground floor of the premises of Messrs. G. Thorpe and Co., wholesale and retail drapers, of Tyrrel-street and Ivegate. The installation comprises fifteen automatic electric arc lamps of the most approved style, each giving a light equal to 1,200 candles. The internal fittings and working parts of the lamps are mainly silver-plated. Resistance coils, which are placed in the circuit, work automatically, in order that if any one of the lights goes out the remainder are not affected. The globes are unusually large, and are made of alabaster glass, covered with wire netting, and saucers of similar glass are placed underneath to catch any particles of carbon which may fall off, and these do not in any way obstruct the light. The tops of the globes are ornamented with large gilded coronets, which give them a massive and elegant appearance. In order that the attendant who controls the light may see at a glance how much electricity is being supplied to the lamps, a current meter, an instrument answering a similar purpose in relation to electricity to that of the steam gauge in connection with a steam boiler, has been fitted up in the engine room; and, providing for the possibility of an excess of current, fusing pieces, which in such a case would melt and thus prevent damage to the machines or lamps, have been fixed in the circuit. The electricity is generated in a large continuous current dynamo machine, the superiority of which has been proved by long experience; and a Crossley gas engine of 16-horse power supplies the motive force. The effect on the light of the working of the gas engine is scarcely noticeable, special provision having been made to obviate unsteadiness by placing a heavy fly-wheel on the shaft of the dynamo. The light has been used with very satisfactory results, and will presently be in constant use at Messrs. Thorpe and Co.'s premises. A new departure has been taken in electric lighting, so far as Bradford is concerned, by an installation at Mr. F. Illingworth's residence, 5, Ashburnham-grove, Manningham. The entrance hall of Mr. Illingworth's house is illuminated by an arc lamp of 1,000 candle-power, which can be connected or disconnected at will, and a number of small incandescent lamps are switched into the circuit. A set of resistance coils is provided, by which the light may be regulated from a dull red to its full brilliancy. There is also an ammeter, which indicates at a glance the amount of electricity supplied to the lamps. The dining room is lighted by six lamps suspended from the existing chandeliers, to which the current is conveyed by flexible cords of various colours, which do not in any way interfere with the movements of the chandeliers. In the drawing room there are five lamps, similarly arranged, and fixed to ornamental pendants. In the library are three similar lamps. Switches are fixed at the entrance to each room, by which the lights in that particular room can be turned on or out. The electricity is generated by a shunt-wound dynamo, driven by a Crossley gas engine. The light has been in use for some time, and Mr. Illingworth has expressed great satisfaction with it.

THE BALLOON OF THE FUTURE.—In the May part of *Cassell's Magazine* there is a story bearing the above title, which will be found of interest to those who deal in speculative fancy. A lecturer on balloons had just retired to his own particular sanctum, when a visitor was announced, described as a tall, rather stern-looking man, with hair turning grey. He had piercing black eyes, and a rather protuberant forehead. In his hand was a small box, which he laid upon the table.

The visitor's name was Eneas Klampenberger. He was an inventor, a machinist, a dabbler in electrical science, and a student of "currents," atmospheric chiefly. His card declared him to be a "Professor;" and, indeed, it struck us that he did profess too much.

"I have come," said he, "to direct your attention to my model balloon. You, sir, I see by the papers, have been lecturing on balloons. They are useful things, but misunderstood. You must humour them. My balloon is of the future—the great future—which is rapidly approaching."

"Then I am afraid your invention is no use at present," we answered. "Wait till the future comes."

"Then it will no longer be future," he replied—"the present will have arrived—the present *has* arrived—in this box—for you. See!"

That my visitor was a madman I had little doubt, and to get rid of him was my first object. But this was more easily imagined than effected.

Disregarding all hints and suggestions, the Professor unpacked his box, and took out a small balloon neatly folded. From a corner he next extracted a pair of bellows, then a small battery, finally a cylinder, which he informed me contained a supply of "electric motive-power," stored and hermetically sealed, ready for use. This was his patent, and he retailed it in tins for the use of balloonists, as soup and meats are sold to families.

"My dear sir, there is scarcely time for any experiment to-night. I have an article to write."

"I have an article to exhibit," said the Professor, interrupting. "Do you see this balloon? Watch me. You must; you shall; you do!"

I did! I could not help it. I was fascinated, even as the prey of the snake is fascinated by the reptile—the mouse by the cat. I watched my visitor closely.

The Professor half inflated the balloon with the bellows; he then lighted a match, and with it a taper; this prepared gas-taper he held under the toy, and it swelled to all its graceful, rounded form. In the little car he fixed a twin-screw, and inside the car he placed a gas-stove, on which he heated some water. Steam was quickly generated, the twin-screw revolved with tremendous rapidity, and agitated a pair of side wings, or sails, like windmill sails, which beat the air furiously and regularly.

We were speechless. The balloon, now released, ascended half-way to the ceiling, and then round towards the window. The professor ran round the table with the bellows and blew against the model, but it still made its way against the wind, which, indeed, by feeding the sails, assisted the power of the downward stroke, and propelled the balloon upwards, as a kite is sent up, but it still went on.

"There," said the Professor triumphantly, "is not that the balloon of the future?"

"But," we asked, "who suggested the idea? and how is this balloon locomotion managed?"

"Simply by electricity and an application of the primitive laws of physics. Our motive-power by the twin-screw propeller is electricity stored in canisters, and used as required. The sails are utilised when running before the wind; the paddles for beating to windward. I steer by moving the paddles, which catch the wind and sway the balloon. See!"

One of the fluted paddles, was, for a second, turned, and the balloon's course was altered sideways instantly, as the wind acted with greater force in one particular direction.

For the conclusion of the story and the exciting adventures of the lecturer and his uncanny visitor, we must refer our readers to the pages of our contemporary.

ALTERNATING CURRENTS.

BY THOMAS H. BLAKESLEY, M.A., M. INST. C.E.

(CONTINUED FROM PAGE 471.)

The problem of the evenly distributed condenser is somewhat different to the foregoing cases of condensers situated at points of a circuit, in that the current in the conductor at different points is neither the same at two consecutive points, nor in the same phase. Each element of the conductor has its potential continually changing by the excess or defect of the flux of electricity from and to the point considered. Thus, the phase of the potential, the phase of the current, the maximum values of both potential and current will vary according to the point of the conductor considered. Mathematical analysis will serve, therefore, rather better than geometrical demonstration.

The differential equations which express the condition of flow at a point are easily obtained.

Let E be the potential at a point P,
$E+\delta E$ be the potential at a point Q, at distance δx from P,
ρ be the resistance of unit length of the conductor,
C be the capacity of unit length of the conductor,
I be the current at P,
$I+\delta I$ be the current at Q,
δt be an element of time, and δx of length.

Then $\rho \delta x$ is the resistance between P and Q; therefore $\frac{\delta E}{\rho \delta x} = -I$, the current being positive in the direction of the increase of x. Therefore, $\frac{dE}{dx} = -\rho I$. . . . . (α)

The difference between the current at Q and P has during the time δt diminished the potential of the element P Q. Since δE is the decrease of potential and $C \delta x$ is the capacity of the element, the quantity of electricity which has left the element P Q is $-C \delta x . \delta E$, and must be equal to the balance of the current leaving and the current entering the element during the small interval δt.

$$\therefore \delta I . \delta t = -C \delta x . \delta E.$$

Therefore, ultimately

$$\frac{dI}{dx} = -C \frac{dE}{dt} \quad . . . . . \quad (\beta)$$

By differentiating (α)

$$\frac{d^2E}{dx^2} = -\rho \frac{dI}{dx}$$

and combining this with (β)

$$\frac{d^2E}{dx^2} = \rho C \frac{dE}{dt} \quad . . . . . \quad (\gamma)$$

Then these equations must be true in the complete solution of any particular case.

In the case of an infinitely long conductor, if subject to an impressed alternating E.M.F. ϵ whose period is 2 T, the time being measured from its zero phase when its value is increasing (or from the epoch of its ascending node), the solution is

$$\left.\begin{aligned} E &= \epsilon e^{-\sqrt{\frac{\rho C \pi}{2T}} x} \sin \frac{\pi}{T}\left(t - \sqrt{\frac{\rho C T}{2\pi}} x\right) \\ I &= \epsilon \sqrt{\frac{C\pi}{T\rho}} . e^{-\sqrt{\frac{\rho C \pi}{2T}} x} \sin \frac{\pi}{T}\left(t - \sqrt{\frac{\rho C T}{2\pi}} x + \frac{T}{4}\right) \end{aligned}\right\} (\delta)$$

Here x is the distance from the point at which the alternating potential has its maximum value ϵ.

The proof of these formulæ rests upon their satisfying the equations (α), (β), (γ), and the condition that when $x = 0$, the maximum value of the potential is ϵ.

Among points worthy of notice in these formulæ, is (1) that at any point whatsoever the phase of the current precedes the phase of the potential by the same interval of time, viz., $\frac{1}{8}$ of the whole period of revolution, expressed by $\frac{T}{4}$.

(2). Since the phase of either potential value or current is continually postponed in proportion to x, we have a series of points equidistantly situated along the line which are in the same phase of their alternation.

This distance is equal to

$$2\sqrt{\frac{2\pi T}{C\rho}},$$

which may be called the wave length of the undulation.

The series of points bisecting this first series are in an opposite phase.

(3). Although the total resistance of an infinitely long conductor is infinite, still there may be a considerable flow of electricity at any point, if there be capacity distributed along the conductor.

The effect of the current on the dynamometer at any point, x, will be such that if I_1 is the direct current giving the same reading on the same instrument

$$I_1 = \frac{1}{\sqrt{2}} \epsilon \sqrt{\frac{C\pi}{T\rho}} e^{-\sqrt{\frac{\rho C \pi}{2T}} . x.}$$

The reading of the dynamometer will be—

$$\epsilon^2 \frac{C\pi}{2T\rho} . e^{-\sqrt{\frac{\rho C \pi}{2T}} 2x.}$$

or, when $x = 0$, $\epsilon^2 \frac{C\pi}{2T\rho}$, which is equal to $\frac{\epsilon^2}{2\left(\frac{T\rho}{C\pi}\right)}$

By the reading of the dynamometer is meant the angle of the index on a uniform graduation in which the unit angle is that indicated when a direct uniform unit current is passing through the instrument, the coils being in series. Under these circumstances, when an harmonic current is passing through the instrument, of maximum value I, then the reading will be $\frac{I^2}{2}$.

A uniform current, I, would of course produce a reading I^2.

In what follows, therefore, the dynamometer reading may be taken to mean the value of half the square of the maximum value of an harmonic current.

The equations (δ) give the values of the potential and the current at any point of the conductor and at any time. They indicate that these quantities vary harmonically, and the factors which are outside the periodic function of the time give the maximum values of the quantities.

If we were to divide the maximum value of the potential by the maximum value of the current, we should of course get something of the order of resistance, which might in a certain sense be called the equivalent resistance. Performing this operation, this resistance will be found to be in every case $\sqrt{\frac{T\rho}{C\pi}}$.

Call this quantity B; it will be wanted in comparison later on.

Since, however, the phase of the E.M.F. lags behind that of the current by $\frac{1}{8}$th of the period, it would be instructive to make the case parallel to one in which a generator of E.M.F. equal to that at any point considered plays into a circuit of resistance r, closed by a perfectly non-leaking condenser of capacity K, and endeavour to find what values must be given to r and K, so that the current may be the one at the point considered in phase and magnitude. Then r and K may be more properly called the equivalent resistance and the equivalent capacity of the infinitely long circuit.

The necessary values are found thus :—

Since the current precedes the E.M.F. by one-eighth of the period, the geometrical diagram of the E.M.F.'s concerned will be a right-angled triangle, having each of the smaller angles equal to $\frac{\pi}{4}$.

Hence $\frac{K\pi r}{T} = \tan \frac{\pi}{4} = 1$, $\therefore K = \frac{T}{\pi r}$.

Again, the effective E.M.F. bears to the impressed E.M.F. the relation of $1 : \sqrt{2}$, as gathered from the diagram; and the

Digitized by Google

effective E.M.F. divided by the resistance is equal to the current.

Calling α the impressed E.M.F., *i.e.*, the maximum value of E,
β the effective E.M.F.,
γ the current, *i.e.*, the maximum value of I,
for the sake of putting the above statements in algebraical form, we have,

$$\frac{\beta}{\alpha}=\frac{1}{\sqrt{2}}, \qquad \frac{\beta}{r}=\gamma.$$

$$\text{Hence } r=\frac{\beta}{\gamma}=\frac{\alpha}{\sqrt{2}\cdot\gamma}=\frac{1}{\sqrt{2}}\frac{\text{maximum value of E}}{\text{maximum value of I}}.$$

$$\left.\begin{aligned} \therefore \quad r &= \frac{1}{\sqrt{2}}\sqrt{\frac{T\rho}{C\pi}} \\ \text{and} \quad K &= \frac{T}{\pi}\frac{\sqrt{2}\cdot\sqrt{C\pi}}{\sqrt{T\rho}}=\sqrt{\frac{2CT}{\pi\rho}} \end{aligned}\right\} \quad \ldots\ldots \quad (\epsilon)$$

Thus the equivalent resistance varies as the square root of the specific resistance, and inversely as the square root of the specific capacity. The equivalent capacity varies as the square root of the specific capacity, and inversely as the square root of the specific resistance. Both quantities vary as the square root of the period. Their product is equal to $\frac{T}{\pi}$, depending merely on the period.

We have now to consider the cases where the conductor is not infinitely long, but has a length l.

The two important cases are—

(1) When the distant end is put to earth, and is kept, therefore, at zero *potential*.

(2) When the distant end is perfectly insulated, and, therefore, is subject to zero *current* at any instant of time.

These cases are in reality very similar.

Suppose, as before, that the conductor is infinitely long, and that at a point $2l$ distant from the zero point the source of another alternating E.M.F. is inserted, whose maximum value and period are ϵ and 2 T respectively, as in the primary case, but whose phase is *exactly opposite* to the E.M.F. at the zero point. It is clear, then, that the point l from the origin, since it is equidistant from both sources, has its potential raised as much by one alternation as depressed by the other, and the potential will remain, therefore, at zero. The point may put to earth. For the potential and current at any point between 0 and l we have merely to add the effects of the two alternations. We have already expressions for the primary source. Calling those due to the secondary source *reflected* potentials and currents, we have as follows :—

The reflected potential at any point and time will be

$$\epsilon e^{-\sqrt{\frac{\rho C\pi}{2T}}(2l-x)}\sin\frac{\pi}{T}\left\{t-\sqrt{\frac{\rho CT}{2\pi}}\cdot(2l-x)+T\right\},$$

and the reflected current, positive towards the origin of x

$$\epsilon\sqrt{\frac{C\pi}{T\rho}}\cdot e^{\sqrt{\frac{\rho C\pi}{2T}}\cdot(2l-x)}\sin\frac{\pi}{T}\left\{t-\sqrt{\frac{\rho CT}{2\pi}}(2l-x)+\frac{T}{4}+T\right\}$$

Combining the original effect and the reflected effect, and writing for brevity $\sqrt{\frac{\rho C\pi}{2T}}=a$, we have for the potential at any time and place—

$$E=\epsilon e^{-ax}\left\{1+e^{-4a(l-x)}-2e^{-2a(l-x)}\cos 2a(l-x)\right\}^{\frac{1}{2}}\sin\left\{\frac{\pi t}{T}-ax+y\right\},$$

$$\text{where} \quad \tan y=\frac{e^{-2a(l-x)}\sin 2a(l-x)}{1-e^{-2a(l-x)}\cos 2a(l-x)},$$

which shows that the phase of the potential is advanced by the finite conductor being put to earth, compared with the phase at the corresponding point of an infinite conductor.

The current at any point of time or place I is given by

$$I=\epsilon\sqrt{\frac{C\pi}{T\rho}}e^{-ax}\left\{1+e^{-4a(l-x)}+2\cdot e^{-2a(l-x)}\cos 2a(l-x)\right\}^{\frac{1}{2}}\sin\left\{\frac{\pi t}{T}-ax+\frac{\pi}{4}-z\right\},$$

$$\text{where} \quad \tan z=\frac{e^{-2a(l-x)}\sin 2a(l-x)}{1+e^{-2a(l-x)}\cos 2a(l-x)},$$

which shows that the phase of the current is delayed by the finite conductor being put to earth, compared with the phase at the corresponding point of an infinite conductor. We cannot, however, say that the current and E.M.F. at any point differ in phase always by the same amount. The amount varies at different points.

(TO BE CONTINUED.)

ON THE DESIGN AND CONSTRUCTION OF DYNAMOS.

BY GISBERT KAPP.

(CONTINUED FROM PAGE 433.)

In making this assumption as regards self-induction, we tacitly make another, viz., that the ring be subdivided into a sufficient number of sections. If this were not the case the self-induction of each single coil would be considerable, and would vary within wide limits as the current varies. In this case it would not be admissible to simply allow a small percentage of loss of electromotive force, but a much more complicated calculation would be necessary. In practice, however, and especially in incandescent machines, the number of sections in the commutator is always reasonably large (between 24 and 100), and hence the allowance to be made for loss through self-induction very small. Before leaving this subject it will be interesting to point out by the aid of our mechanical model (Fig. 11) the difference existing between arc and incandescent machines. On

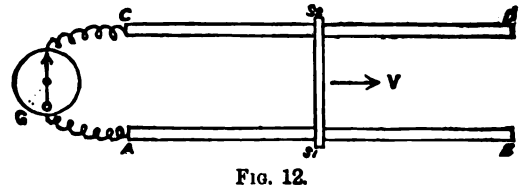

FIG. 12.

account of the greater multiplication of turns in each coil of an arc machine the self-induction is greater than in the coil of an incandescent machine of equal electrical output. That corresponds in our model with an increase of weight of each single roller, and the friction in the journals of each roller is also greater (increased resistance of a larger number of turns of finer wire). If we give the roller sufficient time this increased friction will be nearly or quite sufficient to bring it to rest before the power is applied which reverses the motion. In other words, the angle A O B must be the larger the heavier the rollers. As a matter of fact, we find that the brushes in arc machines are made to lie flat or tangentially on the commutator so as to ensure a greater angle of contact, whilst in incandescent machines the brushes are placed almost end on and the surface of contact is only a little wider than the thickness of the brush. We can now enter into the question of how to calculate the electromotive force of a given dynamo, and in order to place our formulæ on a scientific basis it will be necessary to briefly refer to the absolute units of electromotive force, current, and resistance.*

Let (in Fig. 12) A B, C D be two straight parallel wires placed in a magnetic field of given uniform intensity, I. This means that every square centimetre of surface contained between the two wires is traversed by I lines of force running at right angles to the plane A B C D. The ends A C of the wires are connected with a galvanometer, G, and the circuit is

* See A. Gray's "Absolute Measurements in Electricity and Magnetism;" also Thompson's "Dynamo Electric Machinery."

Digitized by Google

completed by a sliding wire, $s_1 s_2$, which is moved in the direction of the arrow with a velocity of v centimetres per second. If d be the distance between the two parallel wires, the area enclosed by the circuit will be increased through the movement of the slider at the rate of $d v$ square centimetres per second, and the number of lines of force enclosed by the circuit will be increased at the rate of $d v$ I lines per second. The slider, therefore, cuts $d v$ I lines per second, and in doing so it produces a difference of potential between the points s_1 s_2, which in absolute measure is equal to this number of lines. We can therefore write $e = d v$ I. The unit of electromotive force will be produced if each of the three factors d, v, and I are equal to unity—that is, if the parallel wires are one centimetre apart, each square centimetre contains one line of force, and the velocity is one centimetre per second.

Assume that only the slider have a resistance r, but that the galvanometer and the parallel wires have absolutely no resistance. In this case the current indicated by the galvanometer will be expressed by $\frac{e}{r}$, and unit current will be obtained if $e = r$. In a unit field d I $= 1$, and therefore $r = v$. The resistance of the slider can be expressed as the velocity in centimetres per second at which it must be moved across a unit field so as to produce unit current. The relation between these absolute units and the volt, ohm, and ampere employed in practice is as follows :—

One volt equals 10^8 absolute units of electromotive force.
One ohm equals 10^9 absolute units of resistance.
One ampere equals 10^{-1} absolute units of current.

To produce in our slider a difference of electromotive force of one volt, it would have to be moved across a magnet field of unit intensity at a speed of 1,000 kilometres per second. This is an inconveniently large, or, to speak more correctly, an impossible speed, and to reduce it we must employ a stronger field, and increase the distance between the wires. To fix ideas by an example, let us assume that the speed of the slider shall be limited to 10 metres a second, which corresponds to about 22 miles per hour, and is a very moderate speed for the periphery of armatures in dynamo machines. Then to obtain one volt the product d I must equal 100,000, which can be obtained by employing a slider one metre long in a field which contains 1,000 lines of force to the square centimetre, or by a slider 10 centimetres long in a field containing 10,000 lines to the square centimetre, or with any other combination, giving the same total number of lines cut per second. What is the maximum number of lines which can be produced per square centimetre is not definitely known; some say 11,000, others 13,000 to 14,000. In practice, however, such an intensity is never reached. In good machines there are from 6,000 to 8,000 lines to the square centimetre of armature core, which with a drum armature would give about $\frac{6000}{\frac{1}{2}\pi} = 3{,}800$ lines to every square centimetre of the field. Suppose a machine could be constructed, the field of which were formed between the polar surfaces of two magnets standing opposite—something like the Elphinstone-Vincent dynamo—and with just sufficient clearance between them for the armature wire (corresponding to our slider) to pass, and an unlimited exciting power were employed, we would get an ideal dynamo, giving a maximum of electromotive force with a minimum length of wire. At a speed of 60 miles an hour every inch of wire would give about one volt. Such results are, however, not attainable in practice, and we must be content with a much lower electromotive force per inch of armature wire.

Let in Fig. 13 N and S be the poles of the field magnets, and A, B, C, D a drum armature of radius a and length b. The lines of force enter the core above and leave it below, and those lines contained within the rectangle, 2 a b, are useful in producing electromotive force. Let I be the intensity of the field expressed by the number of lines per square centimetre of air space between the polar surface and the armature core. This quantity is never constant throughout the field, but, as is well known, is greatest at the corners of the pole pieces. The exact distribution of lines could be ascertained by an instrument similar in principle to that employed by Mr. Gordon in his alternating current dynamo for the same purpose, or by the method described by Prof. Thompson in his book on dynamo electric machinery. For the present we need not concern ourselves with the exact determination of every part of the field, but we assume that the strength of the field varies in a certain way with the angle α—in other words, that it is a function of α. We can therefore write $I = f(\alpha)$. Assume that the angular distance between two succeeding coils be Δ, and that there be N t external wires, if counted all round the circumference, so that Δ N $t = 2\pi$. It has been shown above how the electromotive force created in a wire depends on the speed at which it moves across the lines of force. Other things remaining the same the electromotive force is simply proportional to the speed. We can therefore assume, for the purpose of our investigation, any convenient speed, and calculate for it the electromotive force. To obtain the electromotive force at any other speed we would have to multiply the result first obtained by the ratio of the two speeds. Assuming, then, that the angular speed of the armature is exactly equal to the angular distance of two neighbouring coils, the wire W_1 would require one second to reach the position previously occupied by its neighbouring wire W_1', and similarly the opposite wire W_2 will advance in one second into the position of W_2'. The electromotive force created in W_1 is evidently $a b \Delta f(\alpha)$, and the sum of all the electromotive forces created in all those wires which are above the horizontal diameter A C is $\Sigma_{\alpha=0}^{\alpha=\pi} a b \Delta f(\alpha)$.

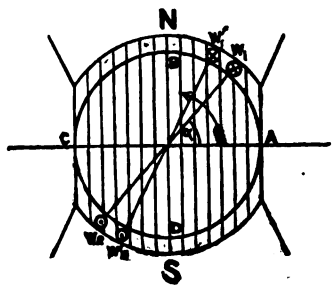

FIG. 13.

Now a, b and Δ are constants, and $\Sigma_{\alpha=0}^{\alpha=\pi} \Delta a f(\alpha)$ is simply the sum of all the lines of force entering the armature core per centimetre of its length above the horizontal diameter A C; and $b \Sigma_{\alpha=0}^{\alpha=\pi} \Delta a f(\alpha)$ is the sum of these lines over the whole length b of the armature. From this it follows that the total electromotive force only depends on the total number of lines passing through the core, but not on the way they are distributed. In consequence of the manner in which the coils are connected up with each other and with the commutator, all the wires above the diameter A C are for the time being placed in series, and similarly all those below A C are in series, the two halves of the armature being at the same time in parallel connection. Let Z be the total number of lines passing across the armature core, then the total electromotive force created within the armature coils is

$$E = Z,$$

the speed being, as assumed above, only equal to $\frac{\Delta}{2\pi} = \frac{1}{N t}$ revolutions per second. If we were to drive the same armature at a speed of n revolutions a second, every thing else remaining the same, the electromotive force would be increased in proportion to the ratio of speeds; that gives

$$E a = Z \frac{n}{\frac{1}{N t}}$$

$$\text{or } E a = Z N t n$$

The electromotive force equals the product of the total number of lines passing across the armature core with the number of external wires, and with the number of revolutions per

second. If Z be given in absolute measure, E a will also be obtained in absolute measure.

In deducing the above formula, we started from a drum armature wound on the Siemens-Hefner-Alteneck principle. The result would have been the same had we taken a Gramme armature as the basis of our investigation, provided we do not count those lines which pass across the central space of the armature. It is evident that a line passing through the central space in the armature must be cut by the inner portion of the coils, and thus create in them an electromotive force opposed to that which is created in the outer coils by the

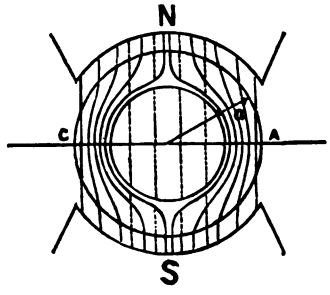

FIG. 14.

cutting of the same line. These lines (dotted in Fig. 14) going straight across the central space contribute, therefore, nothing to the total electromotive force, and must not be included in the value of Z. All the useful lines take the path as shown in full in Fig. 14, and in order that there may be a preponderance of these over the useless lines the space available for their accommodation should be considerable, or, in other words, the radial depth of the core a should be sufficiently great in order that the density of lines should be within the limit of 6,000 or 8,000 lines per square centimetre of core

(TO BE CONTINUED.)

OLD CABLE STORIES RETOLD.—VII.

BY F. C. WEBB.

(CONTINUED FROM PAGE 68.)

THE RED SEA AND INDIA CABLE OF 1859—60.

I left Suez on November 30 for Aden, with Mr. Brunton and Mr. Mayes, in the P. and O. steamer "Emeu." On the 1st December the thermometer was only 75° in the shade, but by the 4th it was 92° on deck, 93° in cabin, 117° in engine room, and 150° in stoke hole. The ship was very crowded.

On the 5th we passed the wreck of the "Alma," on board which ship Mr. Gordon (of Newall, Liddell and Gordon) and Mr. Lionel Gisborne were passengers at the time of the wreck a few months before. They were taken off the island by H.M.S. "Cyclops." We arrived at Aden on December 7th. Mr. and Mrs. Newall were there waiting for the "Imperidor" and "Imperatrix" to arrive. Mr. Long (formerly, and, I believe, now again with Negretti and Zambra) was superintendent in charge at Aden. We arrived at Bombay on the 15th; left the next day for Kurrachee in a wretched steamer called the "Scindian." She only went six knots an hour, and yet we had to stop at night to cool bearings. Arrived on 20th at Kurrachee. Found H.M.S. "Cyclops" there, and we breakfasted on board her; then to Europe Hotel, a curious little building, with a round tower at each corner just like a small Bastile. The only other persons in the hotel were four officers, just down from Delhi, and who had been through the Indian mutiny.

The "Imperidor" arrived and anchored outside on the 24th. A length of 200 miles of cable had been laid several months before from Aden towards Kooria Morria Islands. The "Imperidor" had on her way from Aden hooked up the end and found it covered with coral. The length had become faulty. Mr. Newall at first refused to take Mr. Mayes on board. He had also refused to take from Aden the furniture for Khooria Mooria and Muscat, and had also refused to bring on my batteries, which I had brought as far as Aden, and he refused me a passage in the paying-out ship, although I had a special order from the Board of Directors. He even tried to get Mr. Forde to go in one of the accompanying men-of-war.

The position of the engineers for what may be termed the buying company in submarine telegraphy has always been a peculiar one. The ship and staff for laying the cable are under the contractor, and the unfortunate engineers for the buying company are entirely at the contractor's mercy. I know this from my own experience. I have had also, however, to act for contracting firms as their agent, and I have always looked upon the representatives of the telegraph companies as gentlemen whom it was the interest of my employers to conciliate as far as possible, consistently with a due regard for the solid interests of my employers. But I am afraid this has not always been the key note of many submarine contractors or their agents.

After reams of correspondence at Kurrachee it was finally arranged between Mr. Brunton and Mr. Newall that I should take passage in H.M.S. "Retribution" (32-gun paddle frigate), which ship had arrived at Kurrachee to assist in the expedition.

On January 13 I went on board the "Retribution," commanded by Commodore Harry Edgell, and was introduced to the ward room mess. Fortunately there was a spare ward room cabin, in which I was installed. It was as dark as Erebus, and indeed the ward room itself was nearly as dark as it was on the lower deck, and the after part where the stores, &c., were kept had constant lights burning in the day time.

On the 13th, the "Imperidor" and "Imperatrix" brought up close to Manora Point. The end was landed from the "Imperidor" at 8 a.m., and at 2:10 p.m. she commenced to pay out the first cable for joining India with Europe. She paid out at about 5 knots. We skirted the Mekran coast, and on 14th were going 6½ knots. At about 5 p.m. we sighted H.M.S. "Cyclops" which had gone ahead to sound, and at 5:30 she joined the expedition. At noon this day 119 miles had been run. On 15th "Cyclops" had much difficulty in keeping up with the rest of us, as we were going 7 knots. We went on ahead, sounded, found 15 fathoms and anchored at 2 p.m., 173 miles from Manora Point. "Imperidor" came up paying out and anchored. "Cyclops" reported having sounded across towards Muscat and found 1,900 fathoms as deepest water. On the 16th we got under way at 7:30 a.m., and kept W. by S. in 12 to 16 fathoms. At about 9:45 deepened water, deepened to 500 fathoms by noon. At 10:45 p.m., 99¼ on patent log; "Imperidor" fired rocket. Answered it, and changed course to S.W.W½., and we plunged towards the dreaded deep water. On the 17th high land near Muscat in sight, about 15 miles off; by 9 a.m. went on ahead near to where cable was to land. Noon "Imperidor" arrived. Made signal "Congratulate you." As they came up to us we accompanied them, the ship's company cheering, and the band playing "See the Conquering Hero Comes" (192 by patent log). "Imperidor" brought up to splice on shore end, to pay out to a small bay on the south-western side of Muscat Harbour. The "Retribution" then went into Muscat Harbour, and saluted the flag of the Imaum of Muscat. It was found, however, that although 22 guns were loaded, only 20 had been fired, and the Commodore sent ashore a lieutenant to apologise, and to offer to fire the salute over again, but this was politely declined by the Imaum. The salute was returned by the Imaum from batteries in various concealed places high up amongst the rocks that tower round the harbour, and was a most peculiar sight, which was even novel to the experienced and travelled officers of the ship. Two or three guns were fired apparently out of the rocks in one place, and this was taken up by three or four on the opposite side high up, and then the other side would take it up on a lower level, and you could never tell where the next were coming from, so perfectly concealed were the batteries of this old kind of pirate's nest. Our boats then towed a French sailing frigate further up the harbour.

CONDENSERS.

We invite those of our readers who are Electricians and who have Condensers in their charge to kindly furnish us with information as to the actual capacity of such Condensers as against the nominal value; together with a note of the temperature readings with both wet and dry bulbs; and any other data which may be of interest.

THE INVENTORIES.

Judging by a cursory inspection at the beginning of this week, we might be inclined to predict that the Exhibition of Inventions will not be ready for the opening ceremony on Monday next; but the general activity which prevailed on the premises, the progress made under our very eyes, and the solemn assurances of the management that all would be ready in good time, incline us to take a hopeful view of the situation. Exhibitions are usually behind time, owing to the dilatoriness of the exhibitors. But in this instance it is well known that the offers of exhibits long ago far exceeded the possible space available; and it is perhaps partly on account of the abundance of exhibits actually on the spot that the Commissioners express themselves confident that the Inventories will be quite exceptional in the way of completeness on the day of opening.

Be this as it may, the enlargement of the area of accommodation, the intrinsic interest of the objects to be exhibited, and the many additional provisions made for the comfort and enjoyment of visitors, both inside and outside the exhibition building, leave no room to doubt that, weather being favourable, the forthcoming show will be as popular as the last. People who, under the sanction of authorities on Health, partook of unwholesome drinks, kept late hours, and revelled in crowds which, if not certainly unhealthy, were probably extremely mixed, will not be deterred from taking their recreation in a similar fashion as patrons of Invention. Many, if not most, of these votaries of science probably hold with the saying that the man who invents a new pleasure is the greatest benefactor of his kind. The Inventories, although not altogether a new pleasure, is at all events another; and those who seek for it will find it where they found the last.

There is often a good deal of cant in the talk about combining amusement with instruction; but in sober earnest we see no harm, but rather considerable good, in getting the public to take even a passing stroll through the wonderland of science, even if their ultimate goal be the temple of bliss just over the border. It is impossible to mistake the general impression made on the vast majority who witness such a spectacle as that which will be repeated on Monday next. It is one of wonderment, admiration, and even of awe. It is a sort of revelation to mankind in the aggregate of the great things mankind in particular is capable of achieving; and it increases the general reverence for the exceptionally gifted of their race who employ their talents for the common good of all. Genius is thus encouraged by widening the circle of its admirers; and on the whole genius will not be jealous of the humbler and less serious attractions thrown in as a concession to the weakness of average humanity.

One immense advantage of these South Kensington gatherings is that they are not got up primarily with the object of paying. In reality, and perhaps on this very account, they do pay. But this is not the first consideration; and consequently the arrangements are all on an exceptionally liberal scale. This is manifest in the item of Electric Lighting, which, we believe, will be almost exclusively employed both inside the buildings and for the ornamental gardens in which they stand. A great opportunity will thus be afforded of displaying the many improved devices which have been perfected during the past year. Whatever is new in this department is sure to be found there. One at least of our contemporaries has already, as heretofore, been busily describing things which are certainly not yet there; but on the present occasion we almost expect to see them duly in their places before the season is over, and we hope they may answer to their somewhat premature descriptions.

To inventors themselves—and we allude, of course, more especially to those engaged in electrical improvements—these annual exhibitions serve the double purpose of advertising the wares of the inventor and informing him of the progress or deficiencies of his rivals. On these occasions everybody has an interest in making his ingenuity and researches as widely known as possible; and it follows that by general comparisons on a scale of such magnitude as the present the Inventor's own education will be greatly improved. It is better to learn that we have failed than to waste time on something that has succeeded in other hands.

Exhibitors of electric lighting appliances have again to be thankful for the publicity afforded by this popular exhibition for the display of the new illuminant. The installations, we are confident, will be carried out in a workmanlike way, and on scientific principles. The light will have the advantage of being seen at its best; and the public will receive one more proof of its beauty, its servicableness, and its wholesomeness

Digitized by Google

during the hottest months of the year. It is now past hope that anything will be done during the present Session to rectify the injustices of the Electric Lighting Act. But the lighting of the Inventories is some compensation; and it may prove to be a lever with which even that huge obstruction invented by the Board of Trade will be cleared away.

SUBMARINE TELEGRAPHY.

A general misapprehension prevails in many quarters as to various questions relating to submarine telegraphy. The letter of Sir James Anderson given elsewhere summarises and emphasises the cardinal points to be kept in view—not only in the commercial considerations but also in the political—for the maintenance of cable communication. The primary object, commercially, is to connect points where sufficient business will be developed to obtain a fair return upon the capital expended. The mere laying of a cable between two points is comparatively uninteresting, the questions to be solved are, rather, probable business and cost of maintenance. Either of the three great manufacturing companies would undertake to manufacture and lay a cable between any two points; but the maintenance of the cable is another matter. A somewhat thoughtless suggestion has been made by a contemporary to lay a direct cable between the Cape and India, passing to the eastward of the Mauritius. The objections to such a cable are manifold. The capital required would not be less than one million, the traffic would be small, the cost of maintenance large. With regard to the maintenance, the configuration of the bed of the Indian Ocean is practically unknown, but what is known of it is not reassuring. The depths are great, and experience has shown that the bed is liable to severe vulcanic action. Add to these the surface troubles of currents, winds, and storms, and the look-out is still worse.

Capitalists would not risk their money to carry out such a scheme. The business would simply be that arising between India and the Cape, which is not very great; and this would, of course, be divided between the two routes. We shall say little of the political question, which is outside the commercial question. The necessities of politics are best known to politicians. It is certain, however, that, whether a cable is laid for commercial or political purposes, or a combination of the two, the ability of a foe to injure it remains the same. Sir James Anderson is clear that the cable should be in frequented waters. Natural or wilful damage must be guarded against by despatch boats, and the shorter the distances to be thus bridged the less the evil. In case of war the Government should not only organise a service of swift cruisers to protect the merchant vessels, but every cruiser should be on its guard to protect the cable communications, and should carry one or two men skilled in cable work. These men could grapple for a cable in certain places, connect it up to the instruments on the ship and send cypher messages through, which might be of great value, and this in absolute secresy. Of course it would be necessary to provide a secret code for this purpose.

OBITUARY.—The death is announced of M. Jules Dûcoté, one of the delegates of France at the Conference of St. Petersburg, and who was Director of Postal Telegraphs of the Seine, Paris, at the time of his decease. M. Dûcoté was educated at the Ecole Polytechnique and was connected with the French Administration since the year 1851, during which time he carried out many important works in the technical department of the administration.

CORRESPONDENCE.

PROPOSED CABLE BETWEEN WESTERN AUSTRALIA, MAURITIUS, AND NATAL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of 25th April, quoting from the Mauritius Correspondent of the *Natal Mercury*, it is said the apprehensions I entertain in regard to maintaining submarine cables from the Cape, *viâ* Mauritius, to Australia have been referred to Dr. C. Meldrum, F.R.S., an able meteorologist, who has given it as his decided opinion, *as regards storms*, that this telegraphic route is safer than the route between Ireland and Newfoundland.

I ask leave to say in reply that as regards the frequency of storms I agree with him; but I cannot believe he will differ from me when I say—

1st. That the trade winds along the track referred to are for the greater part of the year strong, and always within two or three points in the same direction.

2nd. That the prevailing winds between Mauritius and the Cape have the same peculiarity.

3rd. That the Agulhas current is so strong as to make the maintenance of a submarine cable as nearly impossible as physical conditions can make it.

4th. That the distance between the points named is excessive, and so are the depths of these broad oceans.

I have crossed the track thirteen times, and my opinion is that it would be very difficult to grapple for a broken cable across the line of wind, waves, and currents which there prevail.

5th. There are hurricanes of overwhelming violence in the region of the trade winds and Mauritius, and a repairing steamer must be large, with great coal endurance, to undertake the repairs in those seas.

6th. For a cable to be of any use commercially between points so distant the conductor must be large, necessitating a larger external covering and ships of greater tonnage to lay it, therefore more expensive in all respects than cables meant for moderate distances.

It is not saying much to say that as regards storms this route is safer than the Atlantic, because irrespective of storms we are seldom in the Atlantic without one or more broken cables.

Two have been broken ever since last September; there are four broken just now. All cables break and require repairs. Some may escape for a few years, but as they get older it is illusory to imagine that they will not break, need repairs, and *renewals*.

I could say more of a disappointing character if I had any real object in preventing cables from being laid between the points referred to; but I have no special desire in the matter. My real point in replying to this notice is to put on record once more, and as briefly as possible, what I do think should be the principles which should govern the selection of a route for submarine cables.

a. Cables should be laid as far as possible where they can most easily be got at to repair.

b. They should be laid in as short sections as convenient—touching at as many points as are likely in the near future to develop some traffic or commercial intercourse of any kind.

Speaking generally, the most useful and economical lengths for cables are from 500 to 1,000 miles, and the depths which we would all select if we could would be between 300 and 1,000 fathoms.

c. Cables should be laid as much as possible along the track usually selected by our mercantile marine, for the two special reasons—1st. When any interruption takes place the broken section can until repairs are effected be more frequently bridged over, and there are more chances of chartering a steamer to continue going between the interrupted points if the interruption seems likely to be prolonged. 2nd, and very important. In time of war the national armed cruisers appointed to patrol the track of our commercial marine would at the same time be guarding the track of the cables.

Digitized by Google

It is all very well to lay cables across great oceans if there is no other way of getting at the points desired, but in my judgment every useful purpose is best served by cables which internationally, intercolonially, and amongst islands touch at as many points as offer some chance of promoting commerce.

For all these reasons any additional cables for Australia will give the best results if they are laid amongst the very numerous and important islands in proximity to the great Australian colonies, and from which more than any other community they will derive the greatest amount of good from any commercial development that may accrue.

In my opinion all money expended in cables across broad oceans, where it can be avoided, is money thrown away.

In time of war they can be easily broken. They can never be easily, quickly, or cheaply repaired. They are therefore strategically unreliable, and in their first cost and maintenance more expensive than those laid as I have suggested.—Yours, &c.,

London, April 27th. JAMES ANDERSON.

PROFESSOR FORBES' REPORT ON THE B.T.K. BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to Prof. Forbes' report on the B.T.K. storage battery, however instructive and satisfactory it may be to the Consolidated Electric Company, I venture to ask of what value is it to those seeking a suitable battery for electric lighting?

We are given two columns of figures (presumably watts), marked "charge" and "discharge," but nothing is said of the rate at which these operations were carried on. The discharge apparently was carried to the extreme point, as the report speaks of several cells having lost their E.M.F.

I am, however, most surprised at the report regarding an "output" as practical when the E.M.F. had fallen 18 per cent., and am interested to know if, in calculating the efficiency, the discharge was carried to this point.

Of what light-giving value would a normal 45 volt 20 candle-power lamp be if the E.M.F. were allowed to drop to 37 volts? Probably 4 or 5 candle-power.

Later on a test is recorded of a specially-prepared battery in which a drop is allowed of 14 per cent. in E.M.F. This is also too great, as for satisfactory electric lighting by incandescent lamps the maximum drop should be 5 per cent.—Yours, &c.,

M. RUDDLE, A.S.T.E. and E.

5, Wellington-terrace, Barton-road, Stretford, Lancashire. 27th April, 1885.

PROF. FERRARIS' EXPERIMENTS WITH GAULARD AND GIBBS' GENERATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I enclose a copy of a letter I have just received from Prof. Ferraris.

I avail myself of his kind permission to send it to you, because I know that it will be most agreeable both to him and to me that it should be known that we are agreed upon this matter.

Prof. Ferraris is in no way in fault. The mistake has arisen from my not being sufficiently explicit.—Yours, &c.,

J. HOPKINSON.

(Copy.)

Turin, April 26th, 1885.

Dr. Hopkinson, F.R.S.

Sir: I thank you heartily for your letter of 21st inst., in which you give me explanations in regard to the method you adopted in determining the efficiency of the secondary generators of Gaulard and Gibbs. Your account which I read in the *Electricien*, of Paris, April 15th, 1884, p. 344, the only one which you had published, only said that your measures were done by means of a quadrant electrometer by the method followed some years ago by M. Joubert in Paris, and this caused me to believe that you had calculated the energy absorbed by the secondary generator by multiplying the mean difference of potential by the mean strength of the current. M. Gaulard had besides strengthened my opinion, so that I thought it unnecessary to write directly to you in order to ask information.

Therefore I was innocently induced to put down your name amongst those of the experimenters who inexactly interpreted their experiments. The explanations you now kindly give me in your letter convince me that I have misunderstood you, which makes me very happy, because I like very much not to be at discord with a man of science whom I esteem highly.

You have done well in publishing your letter in the journals in which abstracts of my paper have appeared. I authorise you to do the same with the present if you think that it is convenient.—Yours, &c.,

(Signed) Prof. Galileo Ferraris.

A WORD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice in your last issue a paragraph relating to the need of a word to express a telephone message.

The words suggested appear to me of doubtful etymology, or so like the word "telegram" as to perhaps cause confusion.

By the word I would suggest the etymology is preserved, but by simply reversing the order of the component parts of the word "tele-phone" a quite distinct word is obtained, and one that cannot be confused with "telegram," "telephone," &c., namely, "Phōnētĕl" (φωνητελ).—Yours, &c.,

29th April, 1885. C. S.

ON THE SEAT OF THE ELECTROMOTIVE FORCES IN THE VOLTAIC CELL.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

(CONTINUED FROM PAGE 497.)

18. Not many measurements of metal pairs have been made, even in air; for mere permutations such as copper-tin, tin-silver, &c., follow at once from the numbers given above by Volta's series law; but in gases other than air one has at present no experimental guidance beyond the barest qualitative one given by Mr. Brown, that copper-nickel reverses its sign when changed from air to hydrochloric acid, and that copper-iron is reversed in sulphuretted hydrogen. But satisfactory observation in these gases is difficult, because they not only *tend* to attack the plates, but they *do* attach them; and so a film is formed and everything is rendered uncertain.

TABLE A.—Energies of Combination of Metals with Chlorine; and Calculated Volta Series in that Gas.

Metal.	Molecule.	Authority.	Heat of Combination.	Calculated Volta series, in Volts.
Zinc	Zn,Cl_2	Thomsen.	97210	2·1

Another complication results from the fact that, when metals are taken out of air and put into a foreign gas, they are already coated with a film of oxygen, and it is not clear in what way this will affect the action of the

* Reprinted from the *Phil. Mag.* for April.

Digitized by Google

new gas. It may have to be replaced almost by substitution ; the affinity to be considered in chlorine, for instance, being something like M, Cl_2 – M, O. In a compound like HCl, the hydrogen also may have to be provided for, the resulting chemical strain being, for instance, M, Cl_2 – M, Cl + H_2, O – 2(H, Cl) ; but the consideration of the hydrogen affinities will not affect *differences*, and therefore will leave comparisons with experiment unaffected. Taking the metals as clean, however, and without air-films, we must suppose the series (Table A) to be right.

This series will hold, as far as *differences* are concerned, for hydrochloric acid also ; because, whatever effect the hydrogen affinity may have in changing the numbers, it will have the same effect on all.

It is easy to write down the hypothetical series in bromine and iodine in the same way :—

Calculated Volta Series in Bromine and Iodine.

Metal.	In Bromine.	In Iodine.
Potassium	3·85	3·50
Zinc	1·74	...
Lead	1·40	·87
Silver	1·10	·60
Copper	·89	·23
Hydrogen	·40	– ·13

All this supposes the metals to be perfectly clean, and not covered with a film of foreign gas like oxygen. On the hypothesis that the metal has been taken recently out of air, and that the film of oxygen with which it is covered has to be torn from the metal, though it was not actually combined with it, the Volta series in chlorine or hydrochloric acid would be quite different, and more like this.

Hypothetical Volta Series of Air coated Metals in Chlorine or HCl.

Silver	1·8
Lead	1·2
Iron	1·1
Copper	·9
Zinc	·85

Unfortunately I can get no data for the heat of chlorination of nickel ; but assuming it not very different from iron, the above series gives copper and nickel in the right order, as observed by Mr. Brown, whereas the other one did not. I have no experiments with which to compare the numbers.

Calculated Volta Series of Clean Metals in Sulphur or Sulphuretted Hydrogen.

Metal.	Heat of Sulphurisation per gramme equivalent.	Volts.
Potassium	91276	1·95
Zinc	41880	·87
Iron	35506	·76
Lead	19112	·41
Copper	18266	·39
Silver	11048	·34
Hydrogen	5482	·12

But it will be observed that this is nothing like the order to be expected in sulphuretted hydrogen ; for it is popularly known that copper is more easily sulphurized in this gas than iron. Now assuming that the metal had been covered with an air-film, and that the oxygen of this has to be replaced by sulphur, the chemical tendency, instead of being M, S, is something more like M, S – M, O, or possibly M, S – M, O + H_2, O – H_2, S ; and either of these will give a quite different order. Data are given on p. 624 of Naumann's *Gmelin-Kraut*, vol. i., for the neutralization-heats of various bases by H_2S, such as CuO + H_2 S, &c. These are something like what we want, and from them we reckon the following :—

Hypothetical Volta Series, in Sulphur or Sulphuretted Hydrogen, of Metallic Oxides, and possibly of Air-coated Metals.

Metal.	Heat of reaction, MO + H_2S = MS + H_2O.	Volts.
Silver	55800	1·20
Mercury	41700	1·04
Copper	31600	·68
Lead	26600	·57
Zinc	19200	·41
Iron	14600	·31
Sodium	7700	·16

The series so obtained gives copper and iron in their proper order ; but it is scarcely likely to be really correct, because it assumes that the *oxides* of the metals are exposed to the gas rather than the metals themselves. It is quite possible that it is not very incorrect for tarnished metals, *i.e.*, metals coated with a film of oxide ; but for ordinary clean metals, coated, not with a film of oxide, but with a film of oxygen, it is nothing but a rough approximation, given because have no better data.

It is to be noted that, as the film of oxygen diffuses away, the Volta-effect depending on it must diminish until at length the active affinity causing the chemical strain is nothing more than M S, or perhaps M S – H_2 S. A gradual falling off and ultimate even reversal of sign was observed by Mr. Brown in both HCl and H_2 S. In so far as actual chemical action occurs and a film of chlorido or sulphide forms, so far of course also will the effect diminish, because it depends essentially on the unsatisfied chemical strain, not on the accomplished chemical action.

Additional Note, March 13th, 1885.

On page 176 of the March Number of the Philosophical Magazine I quote from Von Zahn and others an extraordinary statement, ascribed to Professor Exner, that a thermopile ceases to work in a vacuum, saying at the same time that I had been unable to find the statement myself in Exner's writings. For a sufficient reason as it now turns out, because it is not there.

Turning over some back volumes of 'Nature' recently, I accidentally came across a letter from Professor Exner in vol. xxiii., p, 170, December, 1880, denying that he had ever said such a thing, and maintaining that his memoirs were quite clear on the subject of the relation, or rather want of relation, between voltaic and thermoelectric phenomena. This is perfectly true. Professor Exner has expressed himself on this subject with decision, and finds fault with Professor Edlund for ever confusing the two distinct things together.

In the same volume of 'Nature,' on page 312, appears a note from Professor Young acknowledging that he ought to have been more careful to refer to the original statement, and giving one of the "Physical Notes" of 'Nature,' p. 156, vol. xxii., as his authority. This "Physical Note" quotes from *l'Electricité*, and so the error, however originally manufactured, gets handed on from one paper to another.

One of the memoirs which I have unfortunately overlooked in my historical sketch of the experimental work done in connection with the subject has come to hand this morning, through the kindness of the authors, MM. E. Bichat and R. Blondlot, of Nancy. It was published in the *Comptes Rendus* (1883), t. xc. pp. 1202 et 1293, and in the *Journal de Physique*, 2e série, ii. p. 533, and is an attempt to measure the Volta effect for two liquids. The method employed involves the use of three vessels, A, B, C, of which A and C contain one liquid and B the other. A and B are then connected by a liquid siphon with porous diaphragm [the capillary E.M.F. possibly excited by this diaphragm is bad] ; and the potential of the air between B and C is then rendered uniform [or, commonly speaking, the potentials of B and C are equalised] by making one of the liquids drip inside a cavity kept moist with the other. A and C are connected by platinum electrodes through a compensation resistance-box and battery to a quadrant-electrometer, and the difference of potential between them measured. The arrangement is highly ingenious, but the difficulties of definite and certain measurement must be considerable.

The same physicists have quite recently made a determination, not of the Volta-effect, but of the true contact-force between two liquids, by the use of mercury electrodes ; employing for this purpose a theorem of Helmholtz, that if by judicious polarisation the capillary constant of a mercury-liquid surface be made a maximum, then between the mercury and the liquid there is no difference of potential.*

Their account of this last determination has not yet been published, but it will appear shortly (before this is printed probably) in the *Comptes Rendus*.

The theorem gives evidently an admirably simple method of measuring liquid / liquid contact-force, if it can be made to work practically.

MM. Bichat and Blondlot apparently hope, by a comparison of the two methods, the results of which are quite different (in accordance with the views expressed in the present communication), to be able to obtain values for air / liquid contacts. This would be a most important and useful piece of work : the only difficulty in accomplishing it is the difficulty of getting both sets of measurements thoroughly dependable. I hope they may succeed in overcoming all obstacles.

(TO BE CONTINUED.)

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

Prof. Oliver Lodge's paper on the Seat of Electromotive Force in a Voltaic Cell, read at the preceding meeting, was discussed by the members of this society on Thursday, 23rd ult. Prof. PERRY opened the debate. Remarking first that Prof. Lodge had given rein to his speculative predilections, and had taken too little heed of the observed facts connected with the subject, he proceeded to say that the point in dispute was practically one of Maxwell *versus* Thomson. All the evidence afforded by past experiments since the time of Volta pointed to the conclusions generally accepted until now, and Dr. Lodge ought to furnish very strong reasons for abandoning those conclusions. He had given none of an experimental kind, and had simply contented himself with proving, as he thought, the absurdity of the commonly-received theory. The paper had been misnamed ; it was really an attack on the contact theory. On this Prof. Perry was understood to say that strong evidence existed to show there was a difference of potential between zinc and copper in contact, but that Prof. Ayrton and he had never stated that the electromotive force was at the point of contact. Dr. Lodge had contended that if the observed phenomena resulting from contact were due to contact only, there must be some external supply of energy. Prof. Perry did not see this necessity, and suggested an internal action due to what might be termed tension energy. This he illustrated by reference to weight at the end of a rope raised by an engine. But he preferred an hydraulic analogy, the tendency of electricity to leave copper and enter

* *Monatsberichte der Berliner Akad.* November 3, 1881.

Digitized by Google

zinc, which is called contact force, corresponding with the difference of level in water. He maintained that conclusive experiments had shown there was a difference of potential at the junction of two metals, although the electromotive force was due to chemical action.

Prof. CAREY FOSTER expressed his opinion that Dr. Lodge had given a more satisfactory explanation of the phenomena than any that had gone before, namely, that the E.M.F. comes in where the chemical action takes place ; and that if Dr. Lodge's propositions proved to be correct they would certainly upset the contact theory.

Dr. HOPKINSON thought that this was mainly, after all, a question of definition ; but that Dr. Lodge's would be found the most convenient, as it actually does account for all the known facts, and was, therefore, a better working theory than the old one, which does not. He suggested certain experiments by way of deciding the matters in dispute.

Dr. FLEMING spoke in similar terms.

Prof. FORBES, who read a short communication not very relevant to the question from Sir W. Thomson, was of opinion that the contact theory was as good as any other to work with, and he thought it better than Dr. Lodge's new theory.

Prof. AYRTON described some experiments made in 1878 with bodies at different temperatures, the results of which wholly supported the contact theory. He suggested the probability of electricity residing in the zinc and in the copper, and the possibility of their differing in electrical condition when brought in contact.

Mr. SWINBURNE offered evidence to show that neither of the theories under discussion satisfactorily explained the phenomena, and entered upon a detailed examination of Dr. Lodge's statements ; but as the hour was getting late Mr. Swinburne reserved his remarks for a separate communication to the society.

Prof. SILVANUS THOMPSON, at the invitation of the President, made a brief statement to the effect that no conclusive experiment had ever yet been made establishing the contact theory ; whilst those that had been made were open to precisely the same objection as those which are urged against the conclusions drawn from Mr. Brown's experiments with metals in different gases.

Prof. AYRTON replied that this was not the case, for Mr. Brown's arrangement could not be built up into a series, as in the case of a Daniell cell.

To this Prof. S. THOMPSON rejoined that it could ; and that if anybody had failed it was because they had not gone the right way to work. The difference of potential must inevitably give the E.M.F. if the requisite conditions are complied with in gases as well as in air.

Dr. LODGE replied very fully and with ample illustrations on the black board to the criticisms, chiefly of Profs. Ayrton and Perry ; but as his remarks, although of great interest and delivered with his accustomed felicity and humour, went to reaffirm the salient propositions of his original paper, they need not be reported at greater length here.

A cordial vote of thanks, proposed by the president, Mr. SPAGNOLETTI, was accorded to Dr. LODGE, and the proceedings terminated at an unusually late hour.

PHYSICAL SOCIETY.

At a meeting of this society, held on 25th April, Prof. Guthrie, president, in the chair, the following papers were read :—"On the Theory of Illumination in a Fog," by Lord Rayleigh. The paper dealt with certain theoretical results based upon the assumption that the medium in which the fog was formed, and the substance composing the fog itself, were perfectly transparent. The effect of such a fog surrounding a source of radiation would be to diminish the radiation, and in the case of a supply of energy from without, as with the carbon filament of an incandescent lamp, the temperature of the source would be increased by the fog. A spherical envelope of such a fog surrounding the lamp, and sufficiently thick to be impervious, would act as a perfectly reflecting surface. A problem closely related to the above, and which is easily worked out, is that of light incident normally upon a pile of glass plates. If m be the number of such plates, and ρ the fraction of incident light reflected by one plate, $\phi(m)$ the light reflected, and $\psi(m)$ that transmitted by a pile of m plates, we have

$$\frac{\phi(m)}{2m\rho} = \frac{1}{1+(2m-1)\rho} = \frac{\psi(m)}{1-\rho}.$$

If the transmitted light be allowed to fall upon another pile, consisting of n plates, we have an infinite amount of reflection between the plates, and as the final result, if A denotes the radiation in the original direction, and B that in the opposite,

$$A = \frac{2n\rho+1-\rho}{2(m+n)} \qquad B = \frac{2n\rho}{2(m+n)\rho+1}.$$

If m and n are large, we have $A = B = \frac{n}{m+n}$, which shows that by increasing n we can make the radiation between the plates as much as if the first pile did not exist, whatever the number of plates in it.

"On a Monochromatic Telescope," by Lord Rayleigh, followed by "On the Self-Regulation of the Compound Dynamo," by Prof. A. W. Rücker. If ϕ represents the current or electromotive force in the external circuit of either form of compound dynamo, it is given by means of an equation of the form

$$\phi = \frac{P}{A+x} - \frac{Q}{B+x},$$

where A, B, P, and Q are quantities which are different in different cases, but are always independent of the external resistance, and x is the conductivity or the resistance of the external circuit, according as ϕ represents the E.M.F., or current. The constant A in all cases depends only on the resistance of the various parts of the machine.

If μ and m are respectively the largest and smallest values of x between which self-regulation is aimed at, then $\mu - m$ may be called the *range* of x. That value of x which corresponds to the resistance most frequently used may be called the *usual value* of x, and indicated by ξ.

The maximum efficiency, η, of the machine is connected with A and ξ by the relations

$$A = \xi(1+\eta)/(1-\eta), \text{ if } \phi \text{ be the external E.M.F.}$$
$$A = \xi(1-\eta)/(1+\eta), \text{ if } \phi \text{ be the external current.}$$

It can easily be shown that the function ϕ has two critical values, and that the value of x corresponding to one of these is necessarily negative unless one of the inducing spirals is wound so as to diminish the magnetisation.

Various cases are considered corresponding to different relations among the magnitudes of the constants A, B, P, and Q. The following indications of the method of treatment may suffice:—If $A/B < 1 < \sqrt{P}/\sqrt{Q}$, ϕ is positive for all positive values of x, and the critical value of ϕ occurs for a negative value of x, so that ϕ diminishes as x increases. Hence, if we write

$$\frac{P}{A+m} - \frac{Q}{B+m} = \phi_1$$

we must have

$$\frac{P}{A+\mu} - \frac{Q}{B+\mu} = \frac{\phi_1}{1+q},$$

where q is a positive quantity which will be less as the self-regulation is more perfect. These equations give

$$P = \frac{\phi_1}{1+q} \cdot \frac{\mu - m - q(B+m)}{(A-B)(\mu-m)} (A+\mu)(A+m)$$

$$Q = \frac{\phi_1}{1+q} \cdot \frac{\mu - m - q(A+m)}{(A-B)(\mu-m)} (B+\mu)(B+m).$$

Now, since A − B is negative, we must, if P and Q are positive, have

$$q > (\mu - m)/(A+m)$$

and *a fortiori*

$$q > (\mu - m)/(B+m)$$

By similar methods inferior limits to q are found in other cases, and it is thus shown that for given values of μ and m the limit is lower as A is larger. It has, however, been proved above that if the maximum efficiency of the machine is high, A will be large or small according as it is taken from an expression that gives the external E.M.F. or the external current. Hence it is more difficult to combine high efficiency with good self-regulation if an approximately constant external current is desired than if an approximately constant external E.M.F. is aimed at. The equations do not lead to any simple rules for the relations which should hold between the various parts of compound dynamos ; but if some of the constants are taken as given, the values which must be assigned to the others can be calculated if a given efficiency for the usual value of x, and a given deviation from perfect self-regulation between given values of x are to be attained.

A "Paper on the Determination of the Heat Capacity of a Thermometer," by Mr. J. W. Clarke, brought the proceedings to a close.

THE INTERNATIONAL INVENTIONS EXHIBITION.

The whole of the lighting of the buildings and the illumination of the garden and the terraces at the Inventions Exhibition this year will be carried out by means of the electric light. In 1883-4, there were 252 arc lights and 2,629 incandescent lamps used ; this year there will be 464 arcs, and 5,530 incandescent lamps, without taking into account many thousands of crystal lights. The number of exhibitors of systems of lighting, 21 in all, is the same as at the Health Exhibition, but eight new names appear in the list, filling the places of companies defunct or of firms who from various causes are not among the competitors. The illumination is equal to that of nearly 533,000 candles, the distribution being more exactly reckoned at 108,800 candles for the 5,530 glow lamps, and 424,150 candles for the 464 arc lights. The latter vary from 200 candle-power per lamp of 70 Varley lights, to be placed in the Eastern Arcade and Western Avenue by Messrs. Gaulard and Gibbs, to 5,500 candle-power each for four brilliant Siemens lights in the Conservatory. The highest estimated power for incandescent lights is that of 50 candles per lamp of 250 Bernstein lamps, shown by Messrs. Paterson and Cooper in the dining rooms. Of the Gulcher lamps, 200 exhibited by the Gülcher Electric Light Company in the Chinese restaurant and 250 of the Woodhouse and Rawson lamps are only to be worked to 16 candle-power per lamp. In the "Old London" Street there are five Lea lamps of 2,500 candle-power each, so arranged as to produce the picturesque effect of moonlight in the street and narrow lanes, while the shops and rooms upstairs are lit with 300 incandescent lamps by Messrs. R. E. Crompton and Co., on two dynamos supplied by a 45 horse-

Digitized by Google

power Willans high-speed engine. In the Prince of Wales's Pavilion there are 200 Swan lamps from one dynamo run by a 30 horse-power Elwell-Parker high-speed engine. The Water Pavilion has 250 crystal lamps exhibited by Messrs. Goolden and Trotter. Messrs. Siemens again light the Middle South Court, with 1,080 Swan lamps, of which the light is estimated to be equal to that of 21,600 candles. The new court, contiguous to this, and of equal width, is illuminated by the Anglo-American Brush Electric Light Corporation with 1,000 Victoria incandescent lamps, from three dynamos run by a Kitson-Parsons high-speed engine of 150 horse-power. The new court opening to the left of the entrance to the Central South Court, and occupying the place of the first class refreshment rooms, is supplied by the Edison Swan Company with 1,000 of their own lamps, from dynamos served by a Mather and Platt high-speed engine of 190 horse-power; this company's lamps are also fitted in the subway. Messrs. Clark and Chapman light the grill room with 100 glow lamps, on two dynamos worked by one of their high-speed motor engines of 15 horse-power. The lighting of the aquarium is entrusted to the Gülcher Electric Light Company, who use 800 glow lamps, computed to be worked up to 20 candle-power by two dynamos served by a high-speed Coalbrookdale engine of 120 horse-power. The greatest number of arc lights in any one building will be found in the enlarged east gallery, where Messrs. Thompson, Houston, and Co., exhibit 45 lamps of 1,000 candle-power, and 18 of 600 candle-power each. The south middle gallery has 60 Jablochkoff lamps of 400 candles each; the central gallery takes 50 Gülcher lamps of 1,000 candles each, on dynamos worked by a Westinghouse high-speed engine of 120 horse-power; and the Queen's Gate Annexe (where the Belgian exhibits were placed last year) has 24 Brush lights of 3,000 candles each. Distributed in other parts of the exhibition there are 24 Sun lamps of 1,100 candles; 42 Pilsen lights of 750 candles; and, of the same power per lamp, 16 sent by Messrs. Paterson and Cooper; 24 by Messrs. Cordner, Allen, and Co.; 10 Cardon and 10 Werner, exhibited by Messrs. Clark, Muirhead, and Co.; eight Sennett lamps of 2,500 candle-power each; and 14 Bowman lamps of 700 candle-power, shown by Messrs. Clarke and Bowman. In the gardens six Hochhausen lamps of 3,000 candles are displayed at the mast head by Messrs. Goolden and Trotter; Sir Francis Bolton will employ 12 Siemens lamps, each of 3,000 candle-power, in the illumination of the fountains; and lastly, in the electric light shed 16 Andrewes lights of 800 candles per lamp are used.

REPORT ON ELECTRIC LIGHTING IN THE CITY.

(CONCLUDED FROM PAGE 499.)

6. DOMESTIC LIGHTING.—As our experience of domestic lighting in England is so limited, owing to the expense and difficulty in getting our houses supplied with the requisite power and fitted up with the necessary appliances, I determined to fit up my own house, to enable me to acquire personally the requisite knowledge of the cost and trouble likely to arise in maintaining such an installation. All estimates and calculations of cost, though honest, are unreliable. Figures are so easy to manipulate, and prejudice can so simply exclude or admit essential matters. Facts and real practice are alone reliable. It was not, however, so much to determine the cost, as it was to find out the reliability, to discover the faults, the troubles, the nuisances, or otherwise the amount of supervision necessary to keep the light going, and generally to learn the possibility of my untechnical neighbours being able to indulge in the luxury of the electric light. Accordingly, I built in my garden a small engine house, sixteen feet by ten feet. In this house was fixed a 2 horse-power Clerk gas engine, manufactured by L. Sterne and Co., of Glasgow. This drives a small dynamo-machine, manufactured by Messrs. Elwell and Parker, of Wolverhampton, whose current charges up seventeen Planté's secondary cells, supplied by the same firm. The dynamo develops a very steady current of 42 volts and 36 amperes, which is equivalent to 1·512 watts, or a little over 2 horse-power. The secondary cells are connected directly to the house by means of copper mains insulated with india rubber, as supplied by the India Rubber, Gutta Percha, and Telegraph Works Company, the same kind of wire, but smaller, being used everywhere for the mains and sub-mains. The switch and lamp leads are of No. 18 copper wire, insulated with gutta percha, having a double layer of cotton braided together into a neat twine, the whole being well paraffined, and supplied by Messrs. W. T. Glover and Co., of Manchester. The lamp fittings are supplied principally by Mr. Tayler Smith, and are of that movable character peculiar to that gentleman's system, and rendered familiar by his well-known exhibit at the International Health Exhibition. The lamps are 31-volt lamps, manufactured by Messrs. Woodhouse and Rawson, which, when worked with a current of ·92 ampere and an electromotive force of 33·4 volts, develop an illuminating power of 10 candles, and give an efficiency of 3·5 watts per candle. Each room has its own circuit, controlled by a switch in the central hall, and protected by a safety cut out. Every fixed lamp has a switch to put it in or out of circuit at will. This is unnecessary for the movable lamps. The engine room has a Cardew voltmeter, to determine the electrical pressure and condition of the batteries, and a simple galvanometer to determine the current flowing into or out of the batteries; a galvanometer is also fixed below the main switch in the hall, to see what number of lamps are burning in the house, to detect any that may be left improperly turned on, and to test the condition of the circuits. There is a constant supply of electricity in the house, and the lights can be turned on and off at any hour of the day or night. The engine room is under the charge of my gardener, who has had no difficulty or trouble whatever in mastering the details of the apparatus, and who attends to everything without materially interfering with his proper duties. He simply lights the gas and sets the engine going. If anything goes wrong an automatically-worked outdoor electric bell attracts his attention to it. When the engine has run the necessary number of hours, he stops it. I have not studied economy. I have been anxious to secure efficiency, and to do everything that was necessary to thoroughly illuminate with safety and simplicity, and without show, a small house like my own. Hence my expenditure at present is no criterion of what it ought to be. I have had to surmount many difficulties and to make many changes, in order to meet my requirements, but I have at last satisfied myself that my installation is practical. I have also been experimenting so much that my consumption of gas is no criterion of what it ought to be. Nevertheless my consumption of gas has been no more than it was during the corresponding quarter last year. My installation has not been going on long enough to enable any accurate estimates to be formed, but I will keep careful record of what is done, and after twelve months' working I will publish the results. I have formed the following conclusions:—1. That electric lighting, when obtained by an isolated plant such as mine, is a luxury that must be paid for as a luxury. I could not with my present experience fit up my house for less than £300, or, say £7 10s. per lamp; but of course this will vary with the artistic taste and character of workmanship displayed in the fittings. 2. I ought not to consume more gas for power than I have hitherto done for light. Indeed, I think I shall consume less. I can say that my house is still lighted by gas, but I now consume my gas in my garden, and not in the house, extracting from it that which I want—*light*—and discharging into the external air that which I do not want—*poison*. Hence I have filtered my light, and purified the air I breathe. 3. The steadiness, charm, and comfort of the light, the durability of my decorations, the absence of heat and of all destructive gases, the nonvitiation of the air of my rooms, and the longer life one gains in consequence, make up a splendid dividend on the capital I have invested. 4. It is idle to deny that there are many difficulties that yet exist to be surmounted, and that can be overcome only by technical skill and experience; but this experience is being rapidly gained, and this technical skill is coming within the reach of all. Anyone with ordinary intelligence and scientific tastes, can have no difficulty in mastering all the details, but electric lighting has not yet reached the simplicity stage of gas. 5. One important item of economy in electric lighting is this, that one need expend energy in light only when and where it is wanted. When gas is used a servant goes round and ignites the gas jets, and they are left for hours to waste away unnecessarily and expensively, whereas with electricity a switch near the door or on the lamp enables one to produce a flood of light only during the time it is wanted, and without a match or taper. Hence if electricity costs twice or thrice that of gas it need be expended only one-half or one-third the time. 6. By the use of such a low pressure as 31 volts, no shocks are possible, nor is there any fear of fire or damage to insulation. Matches and candles are rendered unnecessary, and therefore the security from fire is immensely enhanced. 7. All the trouble and difficulties that I have encountered will be entirely eliminated when electricity can be supplied at our doors as gas is now. They would also be very much reduced if the installation were large enough to justify the employment of a technical hand to look after it. But before electric lighting can be general, the economical distribution of electricity from central points is imperative.

7. CENTRAL STATION LIGHTING.—If electricity could be supplied at our doors in the way prescribed by the Act of 1882, so that we should have a constant service at a constant pressure, all the difficulties that I have experienced in producing my currents in my own house would disappear. Electric lighting would become general—every one would have it if the price were reasonable. But the difficulties and cost involved in distributing the electricity at present are so great that there is not a single central station at work in London. The mechanical and electrical difficulties are being surmounted, but the financial difficulties remain. The Act of 1882 renders it impossible for any company to be formed to carry out the provisions of the Act. Its restrictions are so rigid that it has entirely checked electrical lighting by private enterprise. Of the 73 Provisional Orders obtained in 1883, not one has been persevered with. The only installation that has been carried out under the Act is that at Colchester, and that is done by a company which has a small unexpended capital. Electrical lighting on a large scale means a very large capital expenditure. This capital can now be raised only by the Corporations concerned and on the security of the rates. The Act is of no use for the purpose for which it was passed, and it is questionable whether a local authority like the Commissioners of Sewers of the City of London need regard the Act at all should it determine on establishing an electric lighting system. This, however, is a legal question on which I am not competent to express an opinion. Assuming that it were decided to light up a portion of the City as a tentative measure, the all-important question of the distribution of electricity is a very knotty point indeed to decide. I must confess that I am not convinced as to which is the best system, and without further experience and careful examination I should hesitate to recommend either of the systems I have described as being the best. Indeed, the room for invention in this direction is so extensive, that it may happen that in a short time some plan more perfect and still more economical may be introduced. I intend during my forthcoming visit to America to give this matter the most careful study, and, with the experience gained in Colchester, I trust at the end of the year to be in a position to select a definite system for recommendation. In a report made to the Streets Committee on the 2nd November, 1882, I made the following remark:—"The whole question of the distribution of electricity for lighting purposes is in a very tentative state; sufficient experience has not yet been gained to determine exactly what is required under all circumstances, or even what those circumstances will be, and I think that those corporations who have taken upon themselves to supply electricity have undertaken a responsibility that they have not sufficiently contemplated, and which, with the present state of our knowledge, is extremely difficult

Digitized by Google

to discharge." I venture to remind the committee of the truth of this, and to assert that at the present moment it is still to a great extent the state of the case—electric lighting is unquestionably a great success, but the best means of developing it economically and practically, on an extended scale, have yet to be decided. To attempt to light up a large area with our present experience, and in face of an objectionable Act of Parliament, would be unjustifiable, but to take a small area as a tentative measure, would be a wise and proper course to adopt, and it is that which I very strongly urge the committee to agree to.

8. STREET LIGHTING.—The lamp which, in my judgment, best lends itself to street lighting is the glow lamp, and of the glow lamps I prefer the 50 candle lamp for the main thoroughfares. It was very successfully employed on the Holborn Viaduct, where there were sixteen 16 candle-power (nominal) lamps and seventy-six 32 candle-power (nominal) lamps. No more perfect specimen of street lighting was ever seen than the experimental illumination of the High-street, Wimbledon. The lamps were fixed over the centre of the road. They had not the captivating brilliancy of the arc lamp, but their light was evenly distributed and there was no waste. There would, I fear, be great difficulties in suspending lamps over the centre of the roadway in the City, owing to the requirements of the Fire Brigade, whose escapes require a headway of 35ft., but an admirable effect would still be obtained by fixing these lamps on posts on the curbstone, as at present, and 50ft. apart. I should much like the Streets Committee to select a main thoroughfare, and allow the experiment to be tried. Whatever difficulties there may be in introducing domestic electric lighting cease altogether when we regard street lighting. There is no difficulty in distributing the current; the whole of the streets of the City could be illuminated from one centre; the lights could be turned on and off in one second; and if the power required to produce the currents were obtained from gas engines, then on the approach of fogs the streets could be instantaneously lighted without sending round any lamplighter.

THE COMMITTEE ON OVERHEAD WIRES.

The Select Committee of the House of Commons resumed their inquiry again on Thursday, Mr. G. Russell presiding.

The first witness for the day was Mr. PILDITCH, surveyor to the Wandsworth Local Board. In the course of his examination he stated that in 1884 a telephone company sought to fix certain wires in the Wandsworth district, and on the Local Board resisting that a case was submitted to Mr. Justice Stephen, who gave judgment in favour of the Board. Subsequently that decision was reversed, with the result that the Company were left free to fix wires without restriction. The Board now felt that some restrictions should be placed upon telephone companies; that the local authorities should have the right of granting licences, and should also have absolute power to decide whether wires should be laid under or over ground, without any appeal. Numerous accidents had occurred in this district, one having had a fatal result, while several others nearly proved fatal. The Board would rather all the wires were underground, but if it was absolutely necessary to allow them to pass over houses, that at least should not be permitted without the supervision of the local authorities. His Board held that wires generally should not be fixed without due notice to them, and that they should then have control as to the height, length, strain, and other points connected in fixing wires. Several of the Post Office wires had broken. There were very many wires in his district, but he could not say to whom they all belonged, for they were often fixed at night or in the early morning without the knowledge or consent of the people in the houses. He had heard many complaints on that ground, but no formal written complaint had been made to the Board. For such cases people had a legal remedy, but very few knew what their legal powers were. The Post Office fixed wires in that way, but he could not give an instance of a telephone company doing so, though both fixed wires pretty much as they pleased.

Mr. GRAY, addressing the Chairman, said he thought some technical evidence ought to be called upon the question of twisting mentioned by the witness, as this was a point of great importance.

Mr. ALLISON, city surveyor of Manchester, the next witness, informed the committee that during the last three or four years there had been a great increase of wires in Manchester, and although he would not go so far as to say all wires ought to be placed underground, he was in favour generally of that system. In Manchester there had been several accidents through wires breaking. The Corporation spent £50,000 annually in widening and opening up streets, and they consider it unfair that telephone companies and telegraph companies should be allowed to fix wires overhead in an unsightly manner. Wires fixed diagonally across streets were very objectionable, and at least they ought to be fixed at right angles. He believed the average duration of a wire in his district would be from four to five years. Where overhead wires were permitted, provision should be made for their removal if necessary as interfering with property or if otherwise objectionable, and there ought also to be a minimum height of 40ft. fixed to enable fire-escapes to pass under. He would allow no right to be acquired by the owner of wires through user or lapse of time, and he would require every wire to be registered in order to fix the ownership and liability. The Corporation had obtained an Act enabling them to frame bye-laws, but they had not put it in force, because they wished first to gain experience. The Act was therefore practically a dead letter, and they had not carried out the inspections they were empowered to make. He would place the Post Office under the same restrictions as the telephone companies, for although most of their wires were underground they might change their system. They had not put their Act in force, because the telephone enterprise was in its infancy, and they did not wish to check or suppress so useful a system. They were perfectly satisfied with the powers their Act gave them as to bye-laws, but they ought to have the control of the wires. They did not wish for power to compel wires being put underground, but they had power at the end of five years to require a wire to be put underground on paying one-third of the cost themselves. They further thought there should be an appeal to the Board of Trade in regard to bye-laws, as it was important to have something like uniformity of bye-lays. He would give telephone companies a right to be heard before the Board of Trade against any bye-laws submitted; but the Corporation would not be prepared to hand over their right of making bye-laws to the Board of Trade, though they would be willing to submit them for approval. A fatal accident had been caused through a wire being two low—only about 25ft. above the street. He thought it would be practicable to make subways for wires under the footpaths in Manchester—at least, for the main trunk lines. No doubt an underground wire would cost more than one overhead, but if a number of underground wires were run together the expense would not be very much greater. The Corporation of Manchester were satisfied with the powers the Act gave them, but they were now realising that they must take some action. They did not wish to strangle the enterprise, but they felt they must have some of the wires put underground.

Mr. DUNSCOMBE, city engineer and borough surveyor of Liverpool, stated that the Corporation of Liverpool had also obtained an Act for framing bye-laws to regulate telegraph and telephone wires. They had framed such bye-laws, and they considered their powers sufficient to protect the public; and on the whole, they thought there was practically no greater danger from overhead wires than from underground wires, if the former were properly put up. They never allowed posts to be erected on the public highways, and as a rule the wires were carried over the house-tops. It was very important in such a city as Liverpool not to increase the necessity for opening the streets, and already great incovenience arose from the power of the Post Office and the gas and water companies to open the streets. The telephone had become a business necessity, and in the opinion of his Corporation every reasonable facility should be afforded for its development, consistently with public safety and convenience. Any large expenditure in carrying lines in iron pipes underground would have to be defrayed by the general public using the lines, and that in many cases would so increase the charges as to render them prohibitory. The cost of subways would have to be borne in the first instance by the local authorities, and for many years the system would be unremunerative, and in Liverpool the sewer system would make the construction of subways very difficult and so costly as to be prohibitive. Mr. Dunscombe insisted that the Corporation must be the authority to make bye-laws, subject to the approval of the Board of Trade, and with a right to the companies to be heard.

Mr. LAWES, C.E., President of the Association of Municipal Engineers, and City Engineer and Town Surveyor of Newcastle-on-Tyne, stated that the members of the Corporation had, with one or two exceptions, uniformly insisted upon telephone and telegraph wires being placed underground. Within the business area of the town they had not relaxed that rule except in one case, but in the thinly populated districts they had allowed wires to be hung from posts. In the exception mentioned leave was given to the Northern District Telephone Company to carry their wires over the Close, which ran parallel with the river, and in which the buildings were intercepted by "chairs" (or passages). In that case there would have been hardship in insisting upon underground wires, and therefore the exception had been allowed. The Corporation had resolved to have telephone and telegraph wires underground through observing the great growth of these wires in other large towns and through fear that these wires would become a source of danger, as they had become in Manchester, Liverpool and other cities. There were some overhead wires in use in Newcastle, but they were so few that they would hardly attract any notice. They had had no accidents, and although the use of the telephone was rapidly spreading they were still able to meet the increase by the underground method. He had communicated by telephone up to ten miles (that was to Sunderland) under the existing system, and he had found the communication distinct and perfectly satisfactory. In fact, the working of this underground system was very satisfactory. He had heard that some of the witnesses had said there were scientific difficulties likely to make an underground system impracticable, but in Newcastle the system was complete and perfectly practicable. As to the question of prohibitory cost, there were 500 members of the telephone exchange in Newcastle, and he had no reason to suppose that the telephone would have been more widely extended if the wires had been carried overhead. Indeed he did not suppose the charges would be reduced if the wires were taken overhead, and he did not believe the action of the Corporation had impeded the development of the telephone. Certainly that would be the last thing they would wish to do. The Corporation had had some transactions with the Post Office, and had always found it easy to work with that Department. The wires were laid in iron pipes placed under the footway, and the operation of placing them was very quickly done. He was afraid a system of large subways, such as had been suggested by some of the witnesses, would be impracticable in Newcastle for many reasons. The Corporation had no special legislative powers relating to telephones, but by virtue of Crown grants in the past they were the owners of the streets, as well as the sanitary authority, and so had at present sufficient safeguards. They did not now wish for extended powers, but in the event of fresh legislation they would wish to be placed in a good position in regard to the control of these wires. In the view of the Corporation, they ought to have general powers to make bye-laws, subject to the sanction of the Board of Trade, and control the wires; but they did not desire any absolute powers, except to prohibit overhead wires. Both the Post Office and the telephone companies had wires under the flags, and in some cases, probably, under the same flags. The branch wires diverged

Digitized by Google

from the main lines in the same way as gas and water pipes were led into houses.

Mr. HORN, of the Westminster Vestry, said he was one of the three witnesses appointed to represent thirteen of the metropolitan vestries. They had frequently considered the subject of overhead wires, and they thought the time had come when it was necessary that Parliament should deal with it. They were of opinion that in any legislation that might be introduced it would be desirable, in the interests of the public, that as a general principle all telephone and telegraph wires should be placed underground—or at least all the main trunk lines and heavy branch lines. As a practical engineer he saw no real difficulies, and as to the cost of underground wires, he thought it had been very much exaggerated. Underground wires might be more expensive at the outset, but they would be more endurable, and in the end cheaper than overhead wires. He regarded the present system as merely temporary by way of experiment. There was great risk of danger from the overhead wires, and many had been reported to have fallen. A few weeks ago it was reported that many hundred wires had fallen during a storm, and he believed that if there had been a severe frost then instead of a thaw the great bulk of the wires would have come down. The vestries held that the public ought not to be exposed to this danger, and they were unanimously of opinion that the control of the wires should be in the hands of the respective vestries and local boards; in the same way as gas and water pipes and telegraph wires were. In the event of a dispute between the vestries in London, or between a vestry and a company, an appeal should be made to the Metropolitan Board of Works, and to the Board of Trade if a vestry could not agree with the Post Office. Certainly where a wire was to be erected overhead the district authority ought to have control, with a power of inspection, but he would not give the Boards an absolute veto.

The committee then adjourned.

On Monday last another sitting of the committee was held under the presidency of Mr. G. W. Russell. The first witness examined was

Sir J. BAZALGETTE, the engineer to the Board of Works, who said that the system of wires in the metropolis was introduced twenty years ago. There was very rarely any overground, and none underground, before that time. During the twenty years that these wires had been in existence the increase had been very rapid. He estimated that there were 800 miles of overhead wires, and ten times that number of underground wires. These wires were subject to the local authorities only when they interfered with the roadway. He knew generally that there had been accidents, but not to a very large extent, and he did not think that what had taken place was any basis for the future. He had no idea of the duration or life of a wire. The Board of Works was a suitable body for controlling the wires, for they had ample machinery which could very readily be applied to that work. The Board of Works might make the bye-laws for the metropolis, and he did not think there would be any advantage in giving an appeal or veto to a Government department. At the same time, private owners would have sufficient protection in the Board of Works, on which they were represented, and then he would give the Board final power, and not allow owners to have a veto, because, if they had a veto, the public safety might be endangered. But, while the Board had a compulsory power, owners should be entitled to pecuniary compensation; and it would be well to require a nominal payment to an owner to prevent a right accruing from user. The Board of Works should make the bye-laws, but the local authorities should be left to see them carried out, and local authorities should also have a right to be heard against any bye-laws laid down. As to the whole of the United Kingdom he thought there should be some limit to the principle of central control, and he believed the question of damage through entering premises could be settled by the local authorities.

Mr. JANSEN, solicitor, next gave evidence on behalf of a number of solicitors and agents representing the Duke of Bedford, the Marquis of Salisbury, Earl Cadogan, several City companies, Guy's, St. Thomas's, and Christ's Hospitals, and a number of very large property owners in London. He explained that, as the manager of the Pollen Estate, his attention had been drawn to the question of wires erected over houses, and from posts, without permission, and he invited a number of the managers and solicitors to meet and consider the subject. They instituted an inquiry, and finding that so many wires had been put up without consent, they served notices on the United Telephone Company to remove the wires. This the company met by giving them an acknowledgment that all of their wires so erected existed only on sufference. A similar acknowledgment had been given to the Duke of Westminster. At their meeting the representatives passed resolutions in favour of greater control over, and a complete registration of these wires, the latter in order to ascertain the ownership of wires, and to prevent wires being put up surreptitiously. Since then they had also come to a conclusion that the sanction of local authorities should be necessary to the fixing of fresh wires, and that wires should be under the control and supervision of the local authorities, with an appeal to the Board of Trade, Local Government Board, or Metropolitan Board of Works. They very much preferred that wires should be laid underground, partly because of public safety and partly because of the unsightliness of overhead wires, and the consequent injury to property. He and those he represented held that the assent of both landlord and occupier ought to be obtained for merely running a wire over a house, and *a fortiori* for making attachments. The telephone was no doubt a great convenience, but he could not regard it as a necessity, and the existence of the telegraphs made the necessity still less.

Mr. PREECE, electrician to the Post Office, was called to give the results of his experience of telephones in America. He said he visited the States in 1877, and brought over the first telephonic instrument that was ever practically used here. At that time there was only one telephone exchange open in America, and the wires were invariably overground; but there had been an enormous development of the telephone as compared with its progress here. In New York and its neighbourhood alone there were more telephone subscribers than there were in the whole of this country, and in Chicago, Baltimore, Boston, and Philadelphia, and other towns there were from 1,000 to 2,000 subscribers. Without exception all the wires were carried overhead, and across the Broadway, New York, there were six distinct lines of poles carrying overhead wires. These poles were fixed in the kerbs, and the result was that the streets were ruined and disfigured in appearance. There had been great outcry there against the wires, but only on the ground of disfigurement and obstruction, and not on public danger. Many of the local legislatures had passed Acts for compelling both telegraph and telephone wires to be put underground, but in no case had this been carried out, for the companies in America did not like to be driven, and their reply was that if they were shown a practical way of working an underground system they would adopt it, unless it was too expensive. He had heard of three or four cases of fire having been caused through electric light currents getting in contact with telegraph and telephone wires, and so diverting the strong currents into an office, and setting fire to the place. In consequence of these fires the electric light companies had adopted a special electro-magnetic "cut-out," which came into operation immediately an electric light current entered a telephone or telegraph wire. Mr. Preece attributed the greater growth of the telephone in America mainly to a higher appreciation of it by the people than was shown here, and stated that, while in one system the cost was equivalent to £42 a year, the general cost was equal to £30 or £35 a year, adding, however, that the telephones and other wires in America were heavily taxed as a source of revenue. There was no scientific difficulty in having an underground system, but there was a practical difficulty. For telegraph purposes an underground system tended to diminish the speed of working and of carrying capacity, and as to telephones the same influence removed the clearness of articulation of speech, and at a certain distance speech became practically impossible along an underground wire. Mr. Preece said he had gone very thoroughly into the circumstances of the Battersea wire case, referred to by a previous witness, and he had come to the conclusion that the only possible means by which that wire could have become so twisted round the lamp post was by its having been rolled round the post by passers-by.

Mr. PATEY, one of the secretaries to the Post Office, being briefly examined, said the Post Office still adhered to the opinions previously expressed as to alterations in the present law, and added that it was very doubtful whether any system of inspection would be useful, because it would tend to remove from the Post Office or telephone officials their sense of responsibility in the case of the wires, and they were most competent, through their constant experience, to properly maintain the wires in safe condition.

Sir GEORGE CAMPBELL, M.P., tendered evidence as a "typical householder," and described the grievance he felt respecting the present state of things. He had, he stated, determined from the first that he would give no authority for placing wires on or over his house in Gloucester-road, feeling that that ought not to be done without the consent and control of the local authority. Wires had, nevertheless, been carried over and attached to his house, by whom and when he could not ascertain. The first wire came he knew not whence, and went he could not tell where—passing from one invisible distance to another invisible distance. During the recent storms the first wire had come loose, and although he gave strict orders to his servants not to allow anyone to go on the roof to repair the wire without explaining who he was, the wire had been mysteriously put up again, and another wire also attached to his side of a parti-chimney stack. Every wire should be registered, and a plan of an intended wire furnished to the local authority, who would then decide whether to grant a license or not.

The committee then adjourned to the 11th inst.

LEGAL:

Irish v. Northern District Telephone Company.

In this case, which came before Mr. Justice Grove, William Edward Irish, an electrician, sought to recover from the Northern District Telephone Company a sum amounting to nearly £100, alleged to be due on certain royalties payable in respect of the use of a patent switch-board, of which the plaintiff is the inventor.

Mr. Lockwood, Q.C., and Mr. Robins were for the plaintiff; Mr. Gates, Q.C., and Mr. Meek, for the defendants.

It appeared that before Mr. Irish had actually obtained the letters patent he entered into an agreement, dated 16th March, 1882, with the company, of which he had been formerly a director, by which he sold them four of the switch-boards he had manufactured, for £250, each board connecting 50 subscribers' wires. The agreement also contained the following clause:—"That within fourteen days of when such letters patent shall be granted the vendor shall execute to the purchasers an assignment thereof, on payment of a rent or royalty in respect of the switch-board to the vendor of 2s. 6d. per every subscriber's wire any such switch-board is made to connect." Upon that clause the plaintiff now sued for the 2s. 6d. per every wire on those four boards. The defendants contended that they had bought the switch-boards out and out, and were therefore entitled to the use of them. Also that the agreement had become merged in the assignment, and they were only liable to pay royalty on the apparatus actually manufactured by them. There was a good deal of difficulty in deciding as to the meaning of the words of the agreement, his

Digitized by Google

lordship remarking that it had been drawn up in about the most confusing manner possible, and at some places was not even grammatical. In the event the learned Judge found for the plaintiff for the sum of £56 10s., being the amount due up to the 27th day of March, 1883.

COMPANIES' MEETINGS & REPORTS.

Eastern Extension, Australasia, and China Telegraph Company (Limited).

The twenty-third ordinary general meeting of this Company was held on Wednesday at the City Terminus Hotel, Cannon-street, under the presidency of John Pender, Esq., M.P.

The SECRETARY (Mr. F. E. Hesse) read the notice convening the meeting and the minutes of the last meeting, which were confirmed by the present meeting.

The CHAIRMAN then said: Although in the report you have a very complete, and I believe faithful, statement of the proceedings of the Company during the six months, still, as usual, I shall repeat some figures and make some remarks on the business of the last half year. The revenue for that period amounted to £248,087, against £231,056 for the corresponding period of 1883, showing an increase of £17,031. The working expenses for the past half year were £79,496, against £69,862 in the corresponding period of 1883, showing an increase of £9,634. Of this, £5,652 is due to the exceptionally heavy expenditure in connection with cable repairs, and the balance is represented by permanent expenses in opening and working the new stations at Tonquin and Macao. The net revenue for the half year was £104,228, against, in the corresponding period of 1883, £117,720, showing an apparent decrease of £13,492. As, however, £20,000 has been charged against the past half year's income on account of the renewal of cables, the net revenue in reality shows an increase of £6,508. Comparing the figures of the whole year the results are as follow:—The revenue in 1884 was £485,759, and in 1883 £444,785, being an increase during the past year of £40,974. The working expenses for 1884 were £146,155, against £132,640 in 1883, being an increase of £13,515. One interim dividend at the rate of 5 per cent. per annum has been paid for the past half year. Another will be posted to the shareholders this evening, together with a bonus of 2s. a share, making, with the distributions during the first half year, a total payment of 7 per cent. for the year 1884. The reserve fund during the past year has been increased by the following additions:—Interest on investments, £13,950; and the balance of revenue to the end of December, 1884, £33,876, together, £47,826, making the total of the fund at the close of the year £510,649, representing 20 per cent. of the share capital of two and a-half millions. During the year we have renewed weak portions of the system (12,660 knots in length) to the extent of 789 nautical miles of brass-ribboned cable. The amounts taken from revenue for this purpose were for the first half year £22,767, and for the past half year £20,000, making a total of £42,767. Up to the present time we have renewed with brass-ribbon type about 1,500 knots of cable; but there are still from 600 to 800 knots exposed to the teredo which will have to be renewed in a similar manner as opportunity offers. That gives you a very clear exposition of the working of our cables, and at the present moment I am glad to say that we have really no interruptions. But we are very seldom without them, and therefore we have to be prepared to deal with them when they occur. The principal cable interruptions, as stated in the report, have been on the Penang-Madras and the Java-Australian sections. The traffic, however, was not appreciably affected, as it was transmitted by the Company's alternative lines. The same remark cannot, however, be made in reference to the interruption of the cable between Tasmania and Victoria. Unfortunately, great inconvenience was caused to the telegraphing public of these colonies, and your Directors have therefore, with a view to giving as reliable a communication as possible, decided to duplicate the line. This will be carried out when a favourable opportunity occurs with cable from our spare stock at Singapore. With regard to our Foochow station, the negotiations to which I have referred at previous meetings, and which have been going on with the Chinese authorities for the past two years, for a more efficient communication with Foochow, have at last been brought to a successful termination by the conclusion of an arrangement for the transmission of the Company's traffic by a direct line between Sharp Peak and Foochow. This line was completed and opened to the public on the 18th ult., and effects a considerable improvement in our communication with Foochow. Having touched upon the principal points of interest in connection with the past half-year's working, it is now my painful duty to refer to the lamentable loss of the ss. "Magneta," which is alluded to in the report. It is the only really dark shadow that has come across our path since the Company was established, and has caused a great deal of pain and sorrow to many outside the Company. Simultaneously with the order for the "Magneta," a sister ship was ordered of the same builders for the Eastern Telegraph Company. We have had a great deal of experience in cable ships, and in designing these vessels an amount of attention was given to them that probably has not often been given to ships; but they were of a technical character—they were literally floating workshops, and every part had to be considered in regard to strength, and the special work which the ships have to perform. I may mention, as to the "Magneta," that the care exercised was such that when the ship was completed the excess over the contract price for extras only amounted to about £24. That I believe is an experience probably unexampled. I believe there is no such evidence of care in all the details as was shown in the building of that ship. I may also mention that the Board visited the vessel, and every one was loud in its praise. The captain who, with the chief electrician, dined with me before starting, told me that he did not believe there was a ship afloat better suited for the work than the "Magneta," that he was proud of his ship, and that he thought he would be able to give a very good account of her when she was brought into active service. So confident was he in his belief as to his safety in the ship that, although he was urged to insure his life before starting, he declined to do so, which is a very sad thing for the family, but such was the fact. I give these details simply to show you that your Board took every possible care to equip a ship which should be in every respect efficient. I took occasion to go out in the other ship, the "Electra," and experienced some very rough weather in the Bay of Biscay, but I was never on board a better sea-going boat. I may mention in conclusion that the ship was fully insured. We shall require to duplicate the vessel. I should be glad to have some expression of sympathy on your part, because it will be necessary for the Directors to do something more than to say they sympathise with the loss which some families have sustained [hear, hear]. I cannot point out any particular case where this may be necessary. I only want an expression of approval and sympathy from you, so that your Board will be able to handle the matter both with delicacy and prudence, and, I hope, with satisfaction to the shareholders. As I have just said, our cables are all in good working order, but it is difficult to say how long they will continue so. I have had a great many inquiries as to what is to be the position of our cables in the event of war. Well, gentlemen, there are altogether about 36,000 miles of submarine cables, and it is very difficult to protect such a large area as these embrace. However, we have submitted to the Government our views, and we hope that as the cables have not only become a necessity for political intercourse, but indispensable for commercial communication, that it will be deemed just as necessary to protect them as mercantile ships from privateering or other attacks. How far it is possible to carry that out is not for me to say. All I can state is that we shall have our repairing ships at the places where we consider they ought to be in the event of any breakage, and I think our position will be such that the Government will see that it is of vital importance to give us such protection as we require for the working of the cables in times of war. It is an old saying that "It is an ill wind that blows no one good." There is no doubt that war does largely increase our traffic. War is about as good a thing while it lasts for increasing the traffic as there could be, because the messages are not measured by words—they are long and continuous. It is scarcely necessary for me to go further into details at the present time, which is a very critical one. We are watching your interests in the very closest way possible, and looking at the successful report which we have put before you to-day, the increase in our reserve fund, and the growing necessity for submarine telegraphic communication, I will only add that during war we have every reason to look forward to a large traffic. I hope the war will be short, if it does occur. If it does not, looking at the great depression, which in a large measure arises through the uncertainty whether there is to be peace or war—when peace is permanently established I look forward to a very considerable change in trade. Trade gets sick many times, but it never dies, and I think the position of Great Britain, as a trading country, is such that whenever a revival takes place we shall have a large share of it, and that the telegraph service will be the very first to show the improvement. I now beg to move the following resolution:—"That the report and accounts of the Directors now submitted be "received and adopted, and that a dividend be now declared of 2s. 6d. "per share, together with a bonus of 2s. per share, both free of income "tax, payable on the 30th instant, making with the previous distribu- "tions a total payment of 7 per cent. for the year 1884."

The Marquis of TWEEDDALE: I beg to second that.

A SHAREHOLDER: Will you tell us how many persons were on board the "Magneta" in addition to the crew?

The CHAIRMAN: Nine, including some young men we were sending out to stations and to attend to other work in connection with the Company. In all, there were fifty-four on board. In reply to a further question the hon. gentleman said: The Board have just arranged to-day to replace the "Magneta"—to build a similar ship—in fact, in almost every respect on precisely the same lines. We shall of course make some slight alterations, but there is so little to do in the way of improvement that I believe the new ship will cost precisely the same as the one which has been lost.

Mr. JOHN NEWTON: Supposing there is a war, and our cables are cut, will you be permitted to charge higher rates—or war rates—for the messages sent over them?

The CHAIRMAN: I think it would not do for me to say that we would make any change or alteration in our tariff. We must wait and be guided by circumstances.

Mr. NEWTON: But you have the power.

The CHAIRMAN: We must be guided by circumstances. Our first consideration is to give a good service, and the next consideration is that such service shall benefit the shareholders.

He then put the resolution, which was carried unanimously. Continuing, he moved the re-election of Mr. C. W. Earle.

Viscount MONCK seconded the motion, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. F. A. BEVAN, Sir Thomas Fairbairn, Bart., was also re-elected to his seat at the Board.

Mr. GIBB next moved the re-election of Mr. Henry Dever, and Messrs. Quilter, Ball, and Company as auditors for the ensuing year, at a remuneration of £100 each.

The motion having been seconded, it was carried unanimously.

The CHAIRMAN: That closes the business of the meeting, and I hope when I meet you six months hence we shall know more about the war than to-day, if there is to be war; but I hope there will be peace.

A SHAREHOLDER moved a vote of thanks to the Chairman and Directors for their able management of the Company's affairs.

Digitized by Google

The motion was seconded and carried unanimously.

The CHAIRMAN: I am very much obliged to you on the part of myself and my colleagues. I am always glad to see fresh faces on occasions like this approving the conduct of the Board. I can only assure you, looking at the time we have passed through and the times we are likely to pass through, your business will require a great deal of care and attention. But you may be sure that our interests are your interests, and that they will be looked after in every way.

The Indo-European Telegraph Company (Limited).

The eighteenth ordinary general meeting of the members of this Company was held at the City Terminus Hotel, Cannon-street, on Thursday last, under the presidency of Colonel James Holland.

The MANAGING DIRECTOR (Mr. W. Andrews) read the notice convening the meeting, and the chairman affixed the seal of the Company to the register of shareholders.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: Gentlemen, when we last year had the honour of meeting you, it was my agreeable duty to mention that the past year had been an uneventful one—a kind of year that is always satisfactory to shareholders. I am glad to be able to report that the year just passed—1884—has also been an uneventful one. There is one circumstance attending it that is to be regretted—very much to be regretted—namely, that commercial affairs have been very stagnant, as we all know, all over the world; and, as the result of that there has been a reduction in the net earnings to the amount of about £1,000; but we have managed to make up the revenue from other sources, so that you see the net loss, as stated in the report, is about that figure. There is also another loss to report, but one which will not very greatly grieve you, namely, a reduction in the expenditure—that is to say, it is about £1,500 less than the expenditure of the preceding year. And when we consider that not only have the wires been kept in far better order than they ever were before, no expense having been spared in keeping everything in perfect order, but also that we have laid out £2,000 as our share of laying a cable across the Straits of Kertch, I think you will admit that as regards the management of our friend, Mr. Andrews, nothing could be more satisfactory; for it is to his untiring zeal and intelligence that we owe this considerable reduction instead of what might have been expected in addition. It is impossible for me, and it would unnecessarily fatigue you, to go into all the details; but I can assure you that not a week passes through the whole year that his mind is not turned, not merely to the reduction of our expenditure, but to the improvement of our means of communication. To show to what extent they have been improved I may mention that in 1884 the average time for a message from London to Teheran has been fifteen minutes, and to Constantinople not more than half an hour. We go as far as Odessa on that line. It is impossible almost that any system of telegraphic communication could be more perfect than that. Among the items of improvement during the year I may mention that we have leased a second wire from the India Office. The German Government, on our communicating that fact to them, with the greatest promptitude placed a second wire on their system also at our disposal from Emden, the nearest point on the coast to Berlin; so that we have two wire communications the whole way to Teheran. There is also, when it is in perfect working order, a two-wire communication from Teheran to India. That portion of the line is under the management of the Indian Government, and I wish I could say that it was as perfect as our own; but it fails occasionally, and does not keep us up to the same degree of excellence that we have managed to attain with the others; but the repair, or renewal, or whatever is requisite on this line, has been taken in hand by the very energetic head of the Indian Telegraphic Department, Colonel Bateman-Champain, and as the Indian Government generally is unwilling to allow matters to slide, but as a rule acts with energy and promptitude, we have every hope that that portion during the year will be placed in as good a condition as our own. I should say that we owe the addition which the German Government has made to our line—the second wire—greatly to the good offices of that very able and energetic Minister, his Excellency Von Stephan, who, on the recognition of his merits, was lately ennobled by the Emperor of Germany. We are fortunate in having so able and efficient a Minister at the German Court. I have very little else, gentlemen, to mention to you, excepting one point, which perhaps you will observe, namely, that we carry over a larger sum than usual. We carry over, instead of a few hundred pounds, a sum of upwards of £4,000. I think that requires no special comment. We all know what the state of political affairs is at present, and we deem it essential in our interest that we should have a good sum to carry over, for no human being can foretell at what moment events may require every thing that we possess in the way of reserve. The reserve fund—which is now a regular reserve fund—amounts to upwards of £50,000, and is a very great sheet-anchor to us, or great support. I wish it were greater, but still it is a highly respectable sum, and we are glad to think that you have on every occasion supported your Directors in steadily increasing that. We think that fund and the insurance that we possess in the joint-purse agreement with the Eastern Telegraph Company of inestimable value to us. It would be indiscreet, and I have no doubt you will all understand my not doing so—to dilate upon the subject of the existing political affairs. We all know what they are, and we all know, as regards the interests of this Company, what dangers may occur. All we can say is that we have lost no opportunity amongst ourselves of endeavouring to safeguard those interests. With these remarks I will conclude by moving "That the report and statement of accounts be received and adopted."

Mr. H. WEAVER seconded the motion.

Mr. MATTHEWS: In the event of the system being interrupted, would the joint-purse arrangement still continue?

The CHAIRMAN: The joint-purse agreement gives us, as I think I stated just now, a very valuable insurance of our property for a certain time. There is no occasion to specify it, but we calculate, should any disturbance occur and last not longer, say than twelve months, that our losses will not be very material. I think, however, that we had better not go into that matter further.

The resolution was then unanimously adopted.

The CHAIRMAN: I have now to move "That a dividend be and is hereby declared for the half year ending 31st December, 1884, of 17s. 6d. per share, making with the interim dividend already paid 6 per cent. for the year, and a bonus of 10s. per share both free of income-tax, making in all 8 per cent for the year."

Mr. J. HERBERT TRITTON seconded the motion, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by Major-General G. B. TREMENHEERE, the retiring Directors, Messrs. C. W. Earle and John Berenberg, were re-elected to their seats at the Board.

The auditors, Messrs. C. F. Kemp Ford and Co., were subsequently reappointed, and a cordial vote of thanks having been passed to the Chairman and Directors, the proceedings terminated.

The Oriental Telephone Company (Limited).

The fifth annual ordinary general meeting of this Company was held on Tuesday, at the Cannon-street Hotel, Mr. William Addison in the chair.

Mr. ALEX. B. CHALMERS, the secretary, read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN moved the adoption of the report.

Mr. HENRY GREWING seconded the motion.

The CHAIRMAN continued: I have a few remarks to make on the report and the position of the Company. It has been the desire of the present Board to lay the position of the Company as plainly as they could before you in the hope that the present arrangement of the accounts will show you the position plainer than they consider they have done before. Some shareholders may think, because nothing very disastrous to the Company was disclosed in the report of the Committee of Investigation, that the report was unsatisfactory. I beg to say that I think quite the contrary, and I am very glad that we had nothing more serious to say. We now know the position of the Company very much better than we did before, and I think it is not in such a hopeless condition as many of us feared it might have been. Many shareholders doubtless feel great anxiety as to the liabilities for guarantees to the Indian companies. The amount this Company will be liable for in that respect during the next three years, taking the revenues of these companies at what they are at present, and without allowing for any prospective improvement, will not probably exceed £10,000; and only under circumstances being so bad as to prevent our being able to realise any of the shares we hold in the subsidiary companies, excepting on such terms as the Directors would not feel justified in accepting, would a call of a shilling a share be necessary, and that would more than meet the whole of this liability. The contingent liability to which reference was made in the balance-sheet was a long outstanding claim of Mr. Leggatt, who was our agent in India promoting the subsidiary companies there. This has now been compromised on terms favourable to this Company. The subscribers to this Company's exchanges, and to those of the affiliated companies, numbered 1,568 in 1884, as against 1,148 in 1883, and additions this year up to latest dates show an increase of 115, representing an addition to this year's revenue of upwards of £1,000. That would be for a period of three months. Our accounts come to about the end of March. The Directors propose to limit their fees for 1885 to £500. I think, gentlemen, this is all I have to say on the report. If any of you have any remarks to make, or questions to ask, I shall be happy to answer them.

A SHAREHOLDER asked how much of the £13,625 put down as sundry debtors was considered good. He would also like to ask how much profit had been made, and what had been the working expenses, and how much dividend had been received on account of the subsidiary companies. With regard to the £10,000 which they would have to pay in the next three years, he would like to know how much of that there was a probability of this Company receiving back.

The CHAIRMAN replied that the amount of debtors, £13,600, they considered to be good; about £8,000 of it was due for the Egyptian indemnity, and a great portion of it represented sums due by different companies. £2,831 was due by the China and Japan Company, and the Telephone Company of Egypt owed them £2,135. The rest was made up of smaller amounts, but they might take them as all good.

Mr. ROBINSON KENDAL said that it was very important that it should be clearly understood that the entire amount of the guarantee for which this Company was responsible in connection with its subsidiary companies was £10,000, and if those companies were in any way successful a large amount of that would come back to this Company. He would ask, if the £10,000 were paid in its entirety, had the Directors any hopes of getting anything back for this Company?

The CHAIRMAN said the amount put down was £10,000, and that amount they might be liable for if the working of those companies remained the same as at present; but if it improved that amount would be reduced by the amount of improvement.

Mr. ROBINSON KENDAL: Then the total loss under any circumstances cannot exceed £10,000, or a shilling a share.

The CHAIRMAN: Taking our position according to the returns we have now.

A SHAREHOLDER asked how Mr. Leggatt's claim had been settled, and for what amount.

Digitized by Google

The CHAIRMAN thought it was not advisable when a compromise had been arrived at that the amount should be stated. He would do so if it were the wish of the shareholders, but he might state that the claim had been reduced by nearly two-thirds of the original claim.

Mr. ADAMS said he must say a word on that as he was Mr. Leggatt's solicitor. He did not think that the Chairman had put it in a fair way. Mr. Leggatt's claim no doubt was for a considerably larger sum than he received, but on the other hand the Company alleged that they had a cross claim. To a certain extent that cross claim was admitted. That had been settled by the Company saying we will give you so much to settle the thing. He took the liberty of advising Mr. Leggatt he had better accept the sum offered him rather than go into litigation with a powerful company. He might say this further, as there was no reason why he should keep it back. When the litigation was begun there was another Board of Directors, and no doubt many of the circumstances connected with Mr. Leggatt's claim affected the individual members of that Board very considerably. They did not affect any of the gentlemen who now sat on the Board; they could fight this case through, and they could have fought it without any fear that any facts could come out that would affect them individually. He would not go so far as to say that the old Board would have suffered in reputation, but there was a certain amount of speculation in reference to the old Board that did not apply to the new Board. He could not say that Mr. Leggatt was content, or that he (Mr. Adams) was content for him, but it would not have been wise for an individual like Mr. Leggatt, who had not much money, to fight a great Company like this.

The CHAIRMAN did not see that the remarks that had been made affected the correctness of the statement he had made.

Mr. HALL said that he was pretty familiar with the circumstances of the case. He was sorry to hear any reflection on the old Board. The old Board was determined to see the thing through, but they had no desire to press hard on a servant of the Company, and they did suggest a compromise, which at the time was refused. It had since been accepted, he thought to the advantage of the Company and also to the advantage of Mr. Leggatt, but he did not think it was fair to gentlemen who were not present that Mr. Adams should say anything reflecting on them individually.

Mr. ROBINSON KENDAL said that although the accounts submitted were not so favourable as they might have been, yet under all the circumstances he thought there was every hope in the future for this Company. With regard to what Mr. Hall had said respecting the late Board, he thought the shareholders were fortunate in having had a report from the Committee of Investigation, who had really discovered nothing of any great importance. The committee expected to find gross inaccuracies, if not malversations, in the affairs of the Company, and the shareholders now had an exact statement of the position of their affairs, and if they left out of the report of the Committee of Investigation injudicious management, for which all men were liable, and if they left out also that after-wisdom for which all men were celebrated, they must come to the conclusion that there was nothing in the report which seriously reflected on the late Board of Management. Personally he had nothing to do with the late management. The Chairman, one of the Directors, and the Secretary assured him that there was nothing wrong in the affairs of the Company, but there might be some few errors of judgment, and he thought that the report of the Committee of Investigation fully verified that statement.

The motion for the adoption of the report was then put and carried.

The retiring Auditors were re-elected, and the proceedings then terminated.

Brazilian Submarine Telegraph Company.

Report and accounts of the Directors for the half-year ended 31st December, 1884, to be submitted to the twenty-third ordinary general meeting, 7th May:—

The revenue for this period amounted to £89,385 3s. 11d., and the working expenses to £21,851 2s. 1d. (including £8,737 6s. for repairs of cable). After providing £8,066 13s. 4d. for debenture interest and sinking fund, and £1,005 14s. 4d. for income tax, there remains a balance of £58,461 14s. 2d.; to this is added £331 2s. 4d., brought forward from 30th June last, making a total of £58,792 16s. 6d. First and second interim dividends amounting to £39,000 have been paid, and £17,000 transferred to the reserve fund, leaving the sum of £2,792 16s. 6d. to be carried to the next account. Since the last general meeting two interruptions of the Company's cables have occurred; one was caused by a ship's anchor disturbing the new Madeira—St. Vincent cable on the 28th November, and the other, which took place on 3rd January, in the old St. Vincent—Pernambuco section, was due to friction upon a reef. The repairs were effected on the 18th December and 19th February respectively, the regular transmission of traffic having been in no way interfered with. All the Company's cables are now in good working order.

Submarine Cables Trust.

Report of the trustees to the fourteenth ordinary annual meeting of the certificate holders, to be held at the offices of the Trust, 66, Old Broad-street, on the 12th inst.:—The revenue for this period, including the balance brought from the previous accounts, viz., £3,943. 9s. 5d., amounted to £24,449. 3s. 6d. Since the last report was issued the trustees have purchased nine certificates at a cost of £886, thus reducing the number of outstanding certificates to 3,381, and the capital of the trust to £338,100. The expenses of the Trust for the twelve months amounted to £1,324. 6s. 10d. The payment of two half-yearly coupons at the rate of 6 per cent. per annum absorbed the sum of £20,289, leaving a balance of £1,949. 16s. 8d. to be carried forward. The dividend and bonus on the Eastern Extension Company's shares (£2,967. 11s.) recently announced, but not payable until 29th April, will be included in the revenue for the current financial year. The securities held by the trustees remain unchanged. The meeting will have to elect two auditors for the current year. Mr. John G. Griffiths and Mr. John Gane offer themselves for re-election.

5 % AUSTRALIAN GOVERNMENT SUBSIDY DEBENTURES.

NOTICE IS HEREBY GIVEN, that in conformity with the terms of the Trust Deed dated 10th May, 1879, the undermentioned numbers of Debentures were drawn by lot on the 29th April, at the City Terminus Hotel, Cannon-street, in the presence of John Pender, Esq., M.P., Sir James Anderson, and others, and of John Venn, Esq., Notary Public.

The said Debentures will be paid off at par on the 1st July next, at the Banking House of Messrs. Barclay, Bevan and Co., 54, Lombard-street, after which date interest on them will cease.

239 Debentures of £100 each.

NOTES.

THE SOUDAN TELEGRAPH LINE.—The telegraph poles and wires have again been destroyed.

NOTICE OF INTERRUPTION.—The Paris and New York Telegraph Company's cable is interrupted.

THE SUBMARINE TELEGRAPH CABLES BILL.—On Tuesday night this Bill passed through its third reading.

FIRE AND WATER.—Some ice houses at Indianapolis, Ind., have been struck by lightning and *burned down*.

SUPERSTITION.—The Charleston negroes believe that if a man is struck by lightning he will never be able to swim again.

THE TELEGRAPH TO MERV.—The Russian telegraphic line towards Merv is completed as far as Kahkaha, 120 miles east of Askabad.

THE WASHINGTON MONUMENT.—The Washington monument has been struck three times by lightning without being in the least damaged.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 1st May amounted to £3,172.

A GOOD SUGGESTION.—The Seismological Society of Japan has suggested the use of telegraph stations to give warning of the approach of earthquakes.

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION.—The Right Hon. Lord Sudeley has joined the Board of Directors of this Corporation.

APPRECIATIVE—The Citizen's Gas Light Company of America are now perfecting arrangements for putting in a plant for electric lights at their works.

TELEMETRY.—Telemetry has been practically applied in America, and has given excellent results, the temperature registrations being exceedingly accurate.

TELEGRAPH FOR THE BLIND.—A telegraph instrument has been designed for the use of blind or deaf people, the vibrations being read or interpreted by the fingers.

THE CENTRAL STATION AT TOURS.—The works at the Central Electric Lighting Station at Tours, already mentioned in our columns, are being rapidly pushed forward.

THE MOON AND ELECTRICITY.—It is stated that there are periodical variations of intensity in terrestrial currents in direct relation with the movement of the moon or the tides.

UNDERGROUND WIRES IN AUSTRALIA.—The telegraph and telephone wires at Melbourne, Australia, are being put underground, great objection having been offered to their presence overhead.

CORRECTING WEIGHT BY ELECTRICITY.—A German mining engineer has introduced the practice of bringing light coins of silver and gold to the standard weight by electro-deposition of the metal on their surfaces.

THE ELECTRIC LIGHT FOR WAR SHIPS.—Messrs. R. E. Crompton and Co. have been instructed by the Admiralty to make seven more sets of electric light machinery for ship use and twenty more projectors.

TELEGRAPH PLANT FOR INDIA.—A contract has been received by Messrs. E. Lucas and Sons, Dronfield Foundry, near Sheffield, for 20,000 telegraph pins for Bombay. They are galvanised, and of very great strength.

DEFENCES OF VICTORIA.—The Victorian Government announce that electric lights may be exhibited at any time from Queenscliffe and Point Nepean for defence purposes, but such lights must not be taken as guiding signals.

THE ELECTRIC LIGHT IN THE DARDANELLES.—The Special Commission sent to inspect the defences of the Dardanelles recommends the establishment of torpedo stations along both shores, and the employment of the electric light to prevent a surprise at night.

PERSONAL.—Major H. S. S. Watkin, Royal Artillery, from Assistant-Superintendent Royal Gunpowder Factory, Waltham Abbey, has been appointed an instructor in topographical science and applied electricity in the Department of Artillery Studies at Woolwich.

CABLE FOR PORT HAMILTON.—The *Globe* understands that an electric cable, connecting Port Hamilton with the nearest station of the Eastern Telegraph Company, a distance of 350 miles, is being laid. The cable is not yet electrically complete, but it is expected that it will be in working order shortly.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—The next meeting of this society will be held at the Institution of Civil Engineers, 25, Great George-street, on Thursday, 14th inst., at 8 p.m., when a paper will be read on "Electrical Definitions, Nomenclature, and Notation," by Prof. Andrew Jamieson, F.R.S.E.

THE ELECTRIC LIGHT FOR MINES.—M. Gaston Trouvé has just perfected an electric glow lamp destined for use in explosive atmospheres. In order to obtain simplicity, the lamp is constructed either to kindle itself on being taken up in the hand, or on being hung up or set down on a stable support.

TELEPHONE RECEIVERS.—The Signal Engineering Company are manufacturing an improved telephone receiver. They claim that by use of a specially designed machine for making the membrane diaphragms and other improvements in manufacture, the instruments will work quite equal to Bell telephones.

CONSOLATION.—The *Norristown Herald* says:—The Supreme Court of Ohio has decided that a subscriber cannot swear over a telephone line without the consent of the company. But the subscriber can derive consolation from the fact that he is still permitted to swear at the company without the consent of the telephone line.

ENTERPRISE IN SPAIN.—Tenders are asked in Madrid for the supply of the material for, and the installation of an electric motor and lighting system, together with a number of receivers, telephones, bells and indicators, lightning conductors, and a clock. Estimate, 34,975 pesetas. Particulars at the Ministry of Finances, Madrid. Tenders 13th May.

AN ANCIENT STRING.—An American society has just come into possession of a piece of the cord which was attached to the famous kite which Benjamin Franklin flew in 1750. It is a fine copper wire, insulated with linen twist. It is said to have been in possession of the donor, who also possesses the original (absolutely the original) club with which Captain Cook was killed, for 50 years.

BOMBAY.—The superintendent of the Eastern Telegraph Company at Bombay, writing on the 10th ultimo, says:—"The news to-day is very warlike. Admiral Sir Wm. Hewett writes: 'We must guard your cables in case of war.' At the present moment it may interest you to know that of 29 members of this staff 24 are volunteers, 10 of whom are 'extra efficients' and 12 efficients."

Digitized by Google

ANOTHER ELECTRIC RAILWAY.—An electric railway is about to be constructed between the village of Saint-Maurice and Pontresina. The motive power will be derived from the waterfall of l'Inn, which will also be utilised to supply the force necessary in the electric lighting of the village. It has been specially stipulated that the new railway shall not in the slightest degree detract from the beauty of the neighbourhood.

COMMUNICATION WITH TRAINS IN MOTION.—Some further successful tests have just been made of the Phelps system in America. Messages were sent and received while the train was running at a rate of 30 miles per hour. The Edison system of railway induction telegraphs utilises the metallic covering of the cars and requires the wire that carries the inducing current to be brought near the roof at various points along the track.

THE INVENTORIES.—The Commissioners of the International Inventions Exhibition have adopted the B.T.K. accumulators in connection with the lighting of the Subway. Eighty of the No. 2 cells are being fitted, a portion of them having been working from the day of opening. The "Consolidated" incandescent lamp of 20 candle-power (90 volts) will be employed in lighting Spiers and Pond's Temperance Refreshment Rooms at the Exhibition.

A NEW EXHIBITION.—A new exhibition has recently been opened in the Champs Elysées, in Paris, in which electricity is largely represented. The Edison Company illustrate the transmission of electrical energy, and have a somewhat novel arrangement in that the generating dynamo actuates at the same time the receiving dynamo and a number of incandescent lamps. Siemens has also put in a small installation of Swan 8 candle-power lamps distributed through the buildings.

UNDERGROUND WIRES IN AMERICA.—The Senate Committee on Miscellaneous Corporations has authorised the appointment of three commissioners to receive the plans which the telegraph companies have prepared to put their wires below ground in New York by November 1. If such plans are not submitted to the commissioners in sixty days after the bill becomes a law, they are authorised to draw up their own plans, and put the wires underground at the expense of the companies.

LIGHTING THE DOVER TURRET.—It has been decided to illuminate the turret on the Admiralty Pier at Dover by means of the electric light, the apparatus for which is being fixed. The turret has hitherto been lighted with gas, but, for different reasons, it has been found advisable to adopt the electric light in the incandescent form. The latter, however, will not be introduced into either the ammunition chamber, which is under the centre of the turret, or the fighting deck, where the 80-ton guns are placed.

ACCUMULATORS.—The electrical engineering works of Messrs. Elwell and Parker, of Wolverhampton, continue to be very busy. The accumulators are continually being increased in size, and now a single accumulator is made which weighs 50 tons, and stores 500 horse-power for lighting. They are also making a battery to supply 3,000 incandescent lamps for the new Central Station, Manchester. Another battery is being made for Sir Thomas Bazley's seat, Hatherop Castle, which will light 750 lamps. The dynamo will be worked by a turbine.

THE NATIONAL TELEPHONE COMPANY. — The National Telephone Company last week completed the new line to Coatbridge and Mossend, connecting their Glasgow exchanges with these places. They have opened an exchange in Coatbridge, with which Coatbridge and Mossend firms are connected, and have made a start with 11 subscribers in Coatbridge and three in Mossend. The wires are working admirably, and the speaking is as clear as in a short distance. Since their erection the wires have been kept constantly at work. It is purposed to keep the Coatbridge Exchange open day and night.

THE ANTWERP EXHIBITION.—This Exhibition was officially opened on Saturday last by the King and Queen of the Belgians. Certain parts of the premises are, we are informed, thrown open each evening to the public. These are the machine works and industrial galleries, and the gardens. Three different systems of lighting are simultaneously employed, *i.e.*, electricity, gas, and petroleum. The former is used in the lighting of the machine rooms, the central industrial gallery, and the gardens; the gas in the works gallery; and petroleum in the public restaurant, which has been established in the open air.

HER MAJESTY'S THEATRE.—This theatre will be opened during the latter end of the present month by Messrs. Boracchi and Corti, the lessees of the Scala Theatre, Milan, with a grand spectacular ballet by Chevalier Manzotti, of Milan, in which electricity plays a great part in the scenic effects. Mr. Shepherd, who is known in Italy for his practical applications of gas and electric lighting for private and public illuminations, and for his successful introduction of the Edison light at La Scala Theatre, Caffe Biffi, the City of Udine, and several industrial establishments in Italy, has been requested to provide the necessary apparatus.

KILL HIM!—An American contemporary gravely announces that a new telephone has been invented by which the crying of a baby may be heard at a distance of a hundred miles. This is an application of the telephone which will make the most nervous individual desirous of interviewing its inventor with a shot gun. Of the eighty-six millions or so of people who drag out an already troubled existence in this country and in America, there may be a dozen or two who yearn to hear the yells of a baby a hundred miles distant, but we doubt it. A contrivance that would prevent the crying of a baby being heard at a distance of ten feet, says our contemporary, is what the sleepless parents of this country demand.

CROSSING THE CHANNEL BY ELECTRICITY.—We are indebted to a contemporary for the information that Mr. Reckenzaun, who has done much for the application of storage batteries to tramcar locomotion, has produced designs for a a torpedo-service launch, to be propelled at high speed by electricity. The conditions enjoined are that this craft should make a voyage across the English Channel and back in moderately fair weather. It is confidently believed that the test can be complied with, and the construction of the vessel and machinery is to be commenced without delay. In view of important improvements in the electrical appliances her speed may be expected to exceed anything hitherto attempted.

THE SS. "CHILTERN."—We learn from Madeira that the ss. "Chiltern," belonging to the Eastern Telegraph Company, has lately completed the laying of two more 4-core cables, for the Portuguese Government, across the Tagus, at Belem. Both cables are powerfully armoured, being furnished with the same type of sheathing as the shore-ends of all the recently laid duplicate sections, excepting that the weight is 22 tons to the knot compared with the 16 tons per knot of the cable shore-ends. Having completed the work, the "Chiltern" left immediately for Gibraltar, *en route* for Zanzibar, to relieve the

Digitized by Google

repairing ship of the Eastern and South African Telegraph Company, the "Great Northern," which has been stationed there since the commencement of 1880.

THE TELEPHONE IN FRANCE.—On the 23rd ult. the number of subscribers of the Société Générale des Telephones was 5,729, as against 5,584 on the 1st of last January. The following figures will give a definite idea of the progress which has been made during the last year. The increase in the number of subscriptions in Paris from the 23rd of April, 1884, to the 23rd of April, 1885, was 332; Bordeaux, 25; Havre, 13; Lyon, 78; Marseilles, 21; Rouen, 16; Nantes, 5; Oran, 6; and Saint-Pièrre-les-Calais 4. The number of lines in actual service is 5,641, of which 3,722 are in Paris. We are informed that some further experiments with the Van Rysselberghe system of telephony are about to be made between Paris and Rheims, a distance of 172 kilometres (106·64 miles).

LIGHTING OF TAY FERRY STEAMERS BY ELECTRIC LIGHT.—The Tay Ferries Committee had under consideration on 30th April a report from the harbour engineer in regard to the better illumination of the Tay Ferries' steamers by the adoption of electric lights, and stating that he had received offers from two companies to supply the necessary machinery and lamps for the sum of £175, and that after examination he recommended the acceptance of the offer of the Edison and Swan United Electric Light Company. The committee agreed to defer consideration of the report till another meeting, and the harbour engineer was instructed to prepare and lay before the committee an estimate of the annual expense which such a system would entail as compared with the present system.

SMART WORK.—Rather a smart feat in electric lighting was accomplished on Monday last at Messrs. Palmer and Co.'s dry dock, Jarrow-on-Tyne, where H.M. transport "Albatross" has been placed for repairs, the completion of which being urgently required necessitated working continuously night and day. In order, therefore, to facilitate the work, Messrs. Palmer considered it advisable to light the dock by electricity, and it is satisfactory to learn that within 8½ hours after receipt of instructions Messrs. Clarke, Chapman, and Co., Gateshead, had one of their new portable electric light machines and boiler delivered at Jarrow, and everything in full working order, the light giving the greatest satisfaction. Evidently such a machine would be very useful during the execution of hurried repairs on board ship, or when docking vessels.—*Liverpool Journal of Commerce.*

TELEPHONES.—The number of sets of telephones exported by the Continental and Tropical American Telephone Company since its contract with the American Bell Telephone Company is said to be as follows:—

	Sets.
Brazil	2,613
Buenos Ayres	2,483
Mexico	3,197
West Coast, South America	911
Venezuela	635
Cuba	592
West Indies	488
Spain	292
U. S. of Colombia	222
Central America	153
	11,586

THE ELECTRIC LIGHT IN GERMANY.—A number of trains on the Frankfort-Fulda-Ulm line are fitted up with a dynamo placed in the luggage van on one side and accumulators on the other side. The dynamo, at a rate of 750 revolutions per minute, gives a current of 12 amperes. The dynamo is driven from one of the axles of the van, in a similar manner to the plan adopted on the London, Brighton, and South Coast trains. The cost of installing the plant is given at £120 for dynamo, driving gear, and accumulators, and at £3. 4s. to £5 per passenger coach. The light itself is estimated to cost about three farthings per lamp hour.—The Edison Company of Germany are about to introduce two new types of arc lamps, which may be placed in derivation in an incandescent lamp circuit. The first of these are of from 300 to 400 candle-power normal, and require a current of 3·5 to 4·5 amperes; while the second gives from 800 to 1,090 candles, with 8 to 9 amperes of current.

A DISINTERESTED LEGISLATOR.—A Belgian contemporary, *La Chronique*, says that some degree of excitement has been caused by the speech of M. Léon Somzée in the Legislative Chamber. M. Somzée is in opposition to the Minister of Railways, who very properly wishes to light all the principal railway stations of the Belgian State by electricity, and incontinently declares that the electric light *ne vaut pas le Diable.* This theory, ventilated in full Parliament, has somewhat exasperated the shareholders of the Société d'Electricité, of which M. Somzée is administrator! It was only after reading the singular discourse of their *mandataire* that they ascertained the fact that the perfidious M. Somzée combines a love of politics with the profession of a gas engineer, and that all his tendresses are therefore naturally reserved for gas, of which he is in a manner of speaking the representative in Brussels.

THE ELECTRIC LIGHT IN PARIS.—We announced in a previous issue that the Edison Society had been instructed to put down an installation of electric light in the offices of the Lycée Louis-le-Grand, situated in the Rue d'Assas. A few experiments were made last week in the presence of the Minister of Public Instruction to determine the best disposition to be adopted for the lamps in the school rooms, and it was then decided to place one lamp of 10 candle-power to each form of four students. A new diorama, which has recently been placed on view in the Champs Elysées, has also received an installation from the same society. This comprises two Edison A dynamos of 100 lamps, a Weyher and Richemond engine of 25 horse-power, and a Belleville boiler. Each tableau is lighted by twenty lamps of 16 candle-power. The passages, staircases, and entrance of the building are also lighted electrically. The new shops of the Maison Boudet, situated at the angle of the Boulevard des Capucines, and the Rue des Capucines are about to receive an installation from the Société le Chrôme, the current being supplied by chromic acid batteries.

THE ELECTRIC LIGHT IN AMERICA.—The Albany Board of Contract and Apportionment has awarded a contract for supplying electric light to the Albany Electric Illuminating Company for five years at fifty cents. per lamp per night for light and attendance, and seven dollars per year per lamp for cleansing lamps. The electric head light recently placed on one of the suburban locomotives of the Illinois Central Railway Company not only gives a brilliant light and illuminates the track for a long distance, but has far greater penetrating power in a fog than the ordinary light. The light is furnished from a small engine with dynamo attachment on the locomotive, and is run with steam from the locomotive boiler. The Aldermen have granted the Citizens' Electric Illuminating Company the right to light certain thoroughfares of the western district of Brooklyn, N.Y., the lamps to be each of 1,200 candle-power;

Digitized by Google

152 electric lights of 1,200 candle-power, 200ft. apart, would be required for this purpose. The cost of the lights would be £5,548, or £36. 10s. each per annum. Should the lights be of 2,000 candle-power, 270ft. apart, 108 lamps would be required, costing £5,518. 16s., or £51. 2s. each. The number of gas lamps displaced would be 852, which cost yearly for lighting £3,496. 14s.

BLEACHING BY ELECTRICITY.—In continuation of our remarks on this subject, we cut the following recipe from the *Dyer*:—Into a cold solution (containing 1 per cent. of bromine) there is poured 1 per cent. of caustic soda at 36° B, or the equivalent of another alkaline base; then the vegetable textile (previously wetted and perfectly saturated with water) is introduced, and is left in the bath until discoloration takes place. After a passage through acidulated water, drying and rinsing take place. One per cent. of sulphuric acid or of nitric acid, poured into the bath when the latter is exhausted by successive discolorations, suffices to place the bromine once more at liberty. By then adding the same proportion of caustic soda, the hypobromite of soda is regenerated. The hydrofluosilicic acid, in composing the bromide and the bromates, forms an insoluble salt of fluosilicate of sodium, which it is easy to eliminate by decantation. In this case there are neither sulphates nor nitrates mixed with the water containing bromine. In the last place, if during the bleaching there are placed in the bath the two electrodes in carbon of one pile, the decoloring oxygen is constantly renewed by the reformation of hypobromous acid. It has also been found that a bath entirely exhausted—that is, only still containing bromides and alkaline bromates—is regenerated by the passage of the current. The same phenomenon is produced with chlorine and its oxygenated compounds. In fact, therefore, M. Bonneville recommends the industrial employment of bromine and hypobromites in the bleaching of vegetable textiles, the regeneration of the baths by acids, and more specially by hydrofluosilicic acid; and the reconstitution of the decoloring power of bleaching agents by means of electricity.

STUDYING TELEPHONE CURRENTS.—Prof. Charles R. Cross has recently described, before the Institute of Technology at Boston, some new apparatus for the study of telephone currents. His first step was to describe at length the method in which currents are formed in the wires of the telephone circuit, and how the changes in their intensity are made to reproduce vibrations caused by the voice. Any ordinary one-direction current, he showed, was easily measurable by the galvanometer. But the telephone current sometimes ran in one direction, sometimes in another, the alternations being very rapid. To obtain indications of such currents as these a special galvanometer had to be used. It was formed of one coil of wire inserted within another, the centre coil being kept in position by a torsion suspender. A current sent through both these coils at the same time tended to bring them both into a position of parallelism towards each other. When reversed, the current was reversed in both coils at the same time, the effect upon the centre coil being thus not intermittent, but continuous, and in the same direction, according to the strength of the current, no matter how often it might be reversed. The centre coil carried a mirror reflecting a beam of light upon the wall, and as the tendency was towards parallelism or away from it, the spot of light was moved as on a scale. This experiment was tried with great success. When the loud-speaking transmitter was used the deflection was very marked; the Bell telephone gave results much inferior. It ought to be mentioned that the effects were only produced with single vowels, such as a, o, u, and y. Judging from the results thus far obtained, Professor Cross was enabled to declare the telephone current to have an enormously greater strength than it has hitherto been supposed to possess.—*Electrical World.*

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—Mr. Alexander Wood, the managing director of this company, has written a letter to the *Financial News* respecting the dispute which has arisen between his company and the Brazilian Government. From it we extract the following:—"The Western and Brazilian Company is the holder of a concession from the Government of Brazil, giving it for 60 years an exclusive right to lay and maintain submarine telegraph cables along the coast of the empire, touching at various ports; in this concession it is stipulated that 'the Government shall remain at liberty to establish electric telegraph communication by land to and from such points as it may deem most convenient, and in the mode which may seem to it best administratively, or by means of a private company; but the tariff of the private lines which compete with those of the concessionaire are not to be lower than those of the submarine lines.' It also contains a clause which stipulates that the parties who may send messages shall be at liberty to forward their telegrams 'either through the submarine cables or by land lines which may be hereafter constructed.' In the year 1878, or five years after this company had been constituted, the Brazilian Administration completed a system of land lines, running parallel with the cables of this company, and connecting all the ports at which said cables touch. Their real object was, however, only too soon apparent, as the tariff upon them was ultimately reduced to a rate which could under no circumstances yield a profit, and which, contrary to the letter and spirit of the concession, showed open hostility to the company. Prompt representations were of course made to the Government, but finding that it received no redress, and that the company could no longer hope for impartial treatment, it under strong protest lowered its tariff to that of the Government lines. Prior to this change of rate the proportion in which the international traffic had been shared was as follows:—The Government took some 44 per cent., the Western and Brazilian Company some 56 per cent., the rates then, be it remembered, being in the case of the Government 1 and 2 francs, and in the case of the Western and Brazilian Company 5½ and 8 francs respectively. As a natural result of this reduction active competition ensued between the land lines and the cables of this company, and the Government got very much the worst of it. The Brazilian Telegraph administration is now said to be about to urge the Government to resort to another and less worthy expedient for improving its position, and it is suggested that the Government should seize upon one paragraph of the concession of the Brazilian Submarine Company and declare that the companies had no right to enter into an agreement which it is alleged is detrimental to the interests of the State, this, too, after said agreement has been in full force for twelve years. In no case has the English investor graver cause for complaint than in this instance, when English capital has been liberally expended on the faith of Brazilian Imperial promises; and if this company is at last to find itself face to face with a high-handed attempt, not only to render the concession which was granted with a great flourish of trumpets abortive and a farce, but also to force the hands of the public to divert their messages from the cables to the land lines, an outcry must ensue, not only in Brazil, but wherever our customers are to be found, when I have no fear as to the verdict which the tribunal of public opinion will pass upon the whole question."

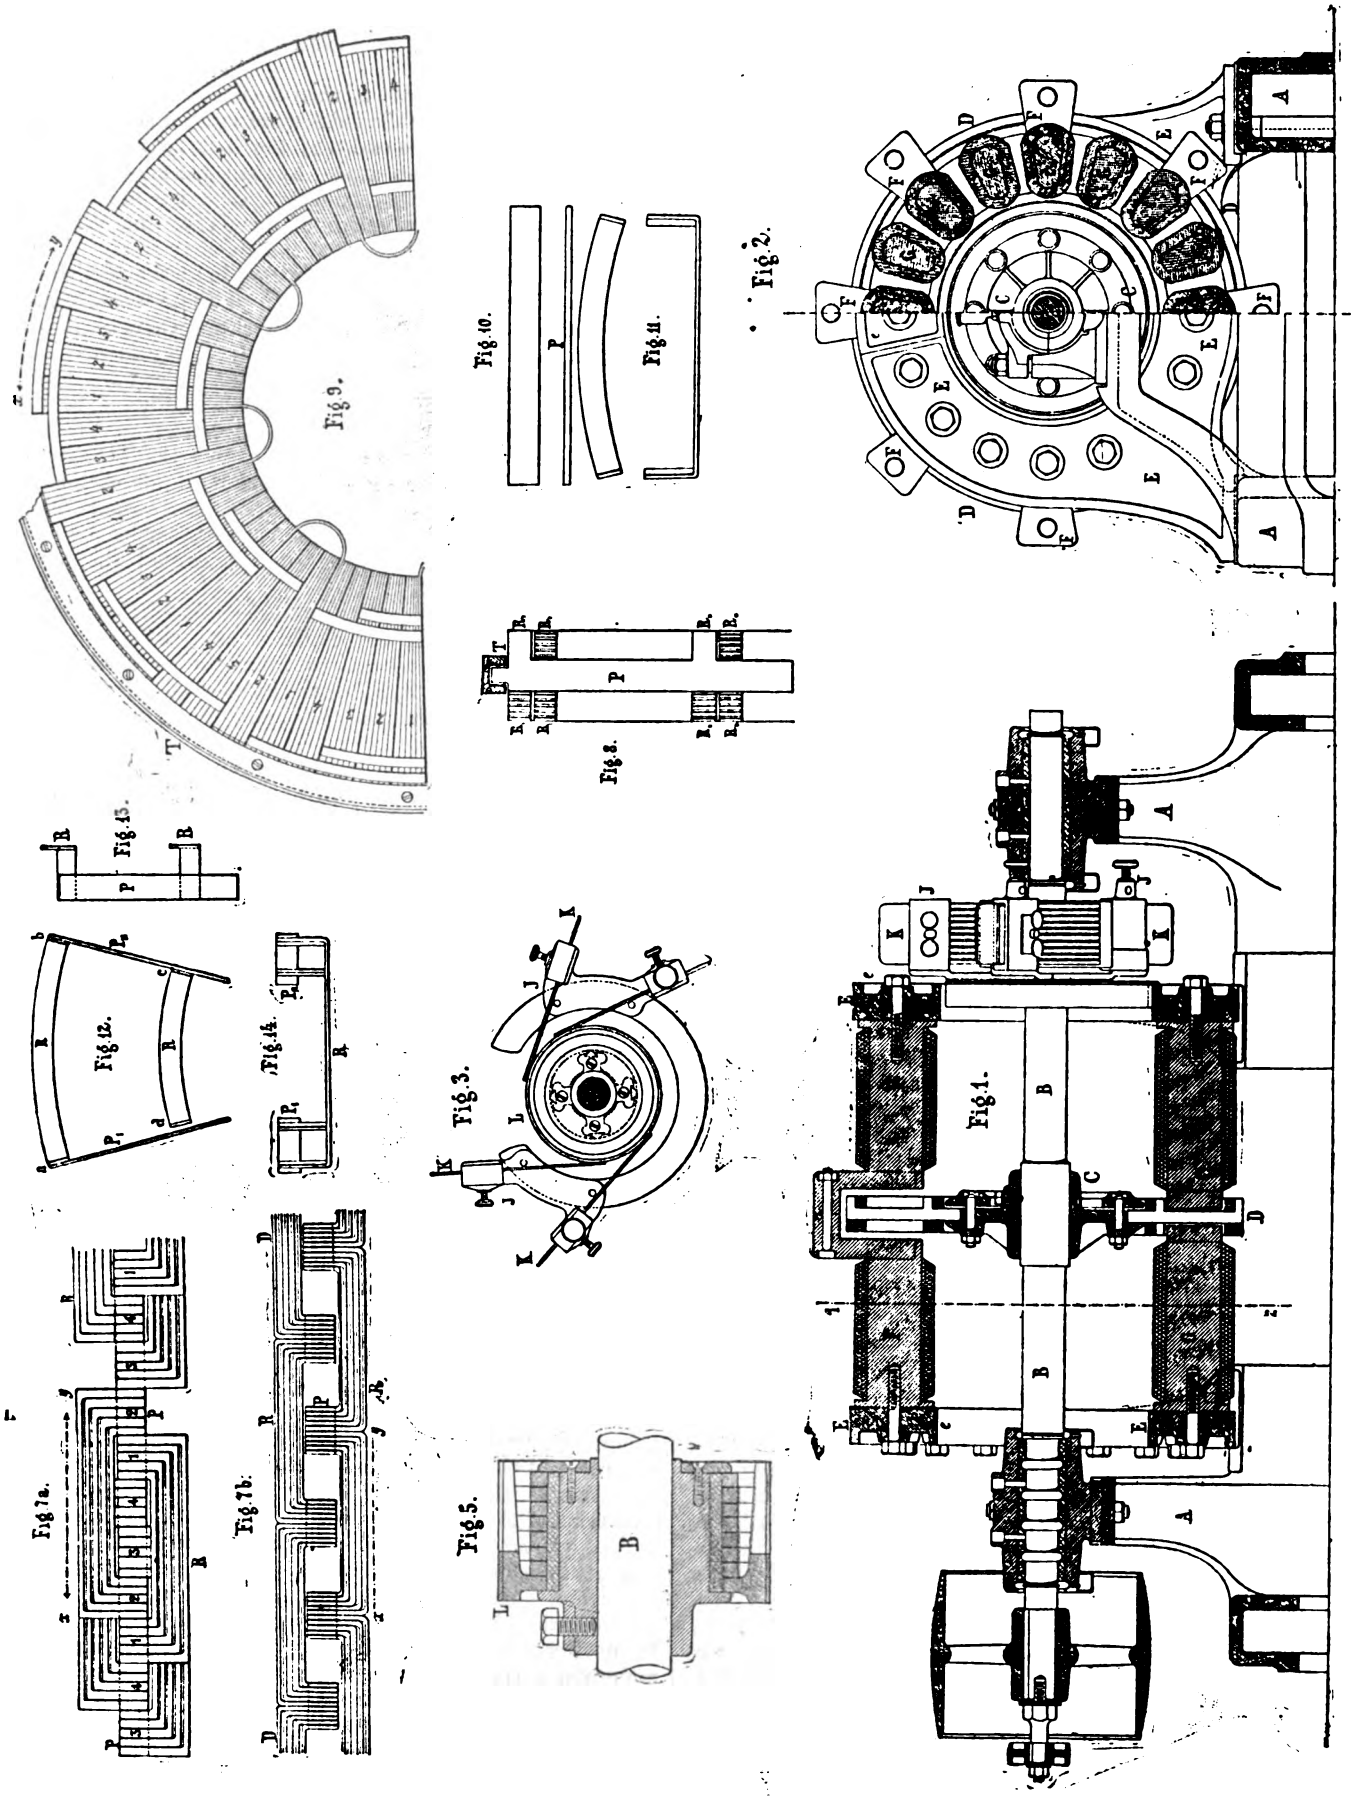
SOME RECENT IMPROVEMENTS IN DYNAMO MACHINES.



For some time past Mr. L. Bollmann, of Vienna, has been engaged in devising improvements to various kinds of electric lighting apparatus, and more recently in the design of a new dynamo, of which great things are expected. The improve-

Digitized by Google

ments which form the subject of our article are among the most important, perhaps, of his designs, in that they relate to three important features in a dynamo having *no iron in its rotating armature*. Broadly speaking, these improvements consist of a peculiar construction of the armature, a new arrangement of the stationary magnets, and of an improvement in the frame, permitting the armature shaft to be easily removed.

Of the drawings given below, Fig. 1 is a section of the entire machine; while Fig. 2 shows a part elevation and a section through the line 1—2 drawn on Fig. 1. In the preliminary experiments which were conducted by the inventor the machine had only 12 pairs of magnets, with open poles, as G G in Fig. 2, and arranged upon the same plan as shown. The pole pieces were 95 millimetres, and the intervening spaces 55 millimetres in breadth, the measurements being taken on the outer circumference. The magnets were in shunt connection, partly in parallel and partly in series; the weight of the whole 24 magnets with windings being 312 kilogrammes, while the weight of the armature disc was 30 kilogrammes of copper. The part between the flanges C, was an inactive weight of about six kilogrammes, thus leaving 24 kilogrammes active. The outside diameter was 60 centimetres, and the thickness between the pole pieces 12 millimetres. The parts were arranged so as to form four circuits, and the length of all radial and circular parts, such as $R_{,} R_{,,}$ in each circuit, was 17 metres in 40 circles, about half of this being in the radial and the remaining portion in the circular parts. The four circuits were connected direct to the commutator in parallel. Of these there were always two and sometimes three in contact with the brushes. In the case of two circuits being in parallel, the internal resistance of the disc was ·002 of an ohm. The total weight of the machine was 700 kilogrammes, and the tension of the current at a speed of 725 revolutions per minute was 38 volts, while at a speed of 775 revolutions per minute the tension was increased to 55 volts. The lamps used, numbering 700, were of 12 candle-power, and it was found that if the number was reduced from this quantity to 100, the variation of the current was only 5 volts, while the changes that took place between 300 and 100, and between 700 and a single lamp were 3 and 8 volts respectively. Upon 1,000 lamps being connected up, and the speed reduced, the alteration of the current was in the same proportion. We are, furthermore, informed that no sort of mechanical regulation was resorted to, and that the disc and magnets remained at their normal temperature. The effects of the machine are said to have been due to the exceedingly small resistance in the disc; to the disposition of copper in the disc, so that the inductive action is uniform; to the connection of the several circuits of the disc in parallel at the commutator; to the absence of iron in the armature; and to the extremely powerful magnetic field distributed over the entire disc. We may now consider the construction in detail.

The frame proper of the machine is constituted by the parts A and E E, while B is the main shaft carrying the double flange C, by means of which the armature disc D is connected to the shaft by a screw, as shown in Fig. 1; an insulating substance being placed between the flange and the disc. To the stands E E are fastened the stationary electromagnets G and F; those situated opposite one another having opposite poles, and those standing side by side having also opposite poles, so that alternately a north pole follows a south pole on the same side of the disc D. There are 16 pairs of magnets used, and they may be arranged in either of the following methods, viz.:—(*a*) All magnets have open pole pieces as G G (Figs. 1 and 2), which stand close to the disc D, but without hindering the rotation of the latter; or (*b*) Every second pair is connected together by iron connecting pieces like F F, which are bent out to form bridges for the disc D to pass freely. The poles of these connected magnets are thereby closed, and cannot act on the disc; but the free magnetism excited in them by their coils is transferred through the iron stands E E to the open poles of the next magnets (which are like G G), so that the field of the latter will now have a double intensity. In this case all active poles on one side of the disc D are north poles, and on the other side south poles. The disc D is constructed of radial parts, P (Fig. 10), and of circular connecting parts, $R_{,} R_{,,}$ (Fig. 11), both of copper. The latter are bent correspondingly to the circle in which they rotate, and their ends are bent angularly, as shown in Fig. 11. The parts $P_{,} P_{,,}$ and $R_{,} R_{,,}$ are then connected together by soldering or otherwise, as shown in Figs. 12, 13, and 14, at the points *a*, *b*, and *c*.

A second similar circle is then made, with the parts $R_{,} R_{,,}$ shorter, so that it can be laid within the first one, without touching anywhere; the end *d* of the first circle is then connected to the second one at *d*. In the same manner are five (more or less) such circles connected, each one rather smaller than the other, narrow strips of insulating material being placed between at the ends, that the air may freely circulate between the parts. A current flowing in at the first end P I, must therefore circulate through all of these five circles, the last of which has no part, $R_{,,}$. Such a connection of 10 radial pieces P, and nine connecting pieces, $R_{,} R_{,,}$, is hereinafter called a segment. Of these there are 32. They are laid one in another, to form the disc, as is shown in Figs. 7, 8, and 9. One half of the segments are made shorter in the radial direction than the other half, which causes the formation of two rows of each of the parts $R_{,} R_{,}$ and $R_{,,} R_{,,}$ on each side of the disc, allowing them to better pass each other without touching. The radial parts P are held together by the flanges C (Fig. 1), and a ring, T, may be laid around the disc, as shown in Figs. 8 and 9.

Fig. 7A represents the outer circumference of the disc, supposed to be laid out flat, and explains how the different sections are connected so as not to interfere with each other. Only the outside row, $R_{,} R_{,}$, of the connecting pieces is to be seen. The angular distance *x y* (Figs. 7, 8, 9) must be equal to the angular distance from one magnet to the next—*i.e.*, to $\frac{1}{16}$th of the circle. Every section is consequently inducted at the same time by two pairs of magnets. The segments are connected to form four different circuits, in such a way that four consecutive segments belong to four separate circuits; each circuit consists, therefore, of eight segments and 80 radial parts, P. Every magnet acts at the same moment on four segments in one direction, and on four on the other. The inductions in the four circuits follow one another, so that while one circuit is in the best position, two others are only partially inducted, and the fourth is in a neutral position. Those segments having similar positions relatively to the magnets are connected in circuit by connecting pieces, which are not seen in the drawings, because they lie inside of the flanges C (Fig. 1). These connecting pieces are joined to the inner free ends of the first and last of the radial parts P, in each segment, and their direction and positions are shown for the series marked with the number 1 in Fig. 9 by the inner arches. The first and last end P of every circuit is, according to the system of connection used, joined either directly to the commutator or to the next circuit.

In order to better understand the induction, we may suppose there to be only a single circuit, so constructed that the inner parts $R_{,,}$ do not return on the left hand to the same section, as in Fig. 12, but towards the right, to the next magnet, as is represented by the thick zigzag line in the Figs. 15, 17, 19, 20, laid out flat. The pole pieces of one row of magnets are represented by shaded squares, and the directions of the molecular magnetic currents, according to the *hypothesis of Ampère*, by fine arrows. The directions of the currents inducted are marked by arrow heads, drawn on the zigzag line. The diagrams, Figs. 15 and 17, relate to the construction of the magnets according to the method *a*, previously mentioned. Fig. 15 shows the parts $P_{,} P_{,,}$ situated in the middle between the north pole *n*, and the south pole, *s*. In moving towards the right, the part $P_{,}$ retreats from the molecular currents of the south pole at its left side, which are directed downwards. This would induct in it a current of equal direction, but simultaneously $P_{,}$ approaches also towards the molecular currents of the north pole *n*, at its right side, which tends to produce a contrary current. Both inductions are opposed to one another, and therefore this position is neutral. $P_{,,}$ is *in every position* inducted exactly the same as P I, but in opposite direction.

In Fig. 17, P I is situated in the centre of the north pole *n*,

Digitized by Google

retreating from all molecular currents at its left, which are directed downwards, and approaching those at its right side, which are directed upwards. Both of these actions induct in $P_{,}$ a powerful current in the upward direction, consequently this is the most active position. The next position will be again, like Fig. 15, neutral, and the second next, like Fig. 17, but in contrary direction. There are therefore during one revolution sixteen alternations of the current in all parts of the disc. When the magnets are arranged according to the method *b*, there will be only one half of the number of poles active, and these will be, on one side of the disc, all of the same sign. The disc remains exactly the same.

Fig. 15.

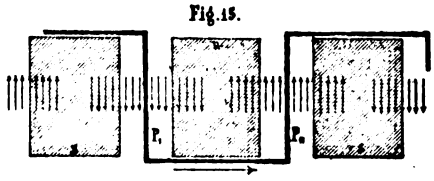


Fig. 17.

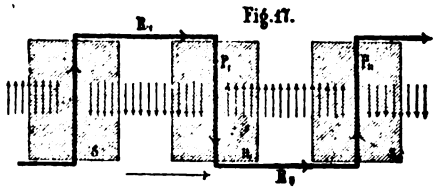

The position (Fig. 19) is now neutral. All poles are south poles. The directions of the molecular currents change, therefore, as well in the middle between two poles as in the central position between the north and south poles of arrangement *a*, and as P retreats from and approaches an equal number of molecular currents in a downward direction, no induction can take place. Fig. 20 is, like Fig. 17, the best position. There are as many alternations per revolution as in the arrangement *a*.

In consequence of the peculiar positions of the parts $R_{,} R_{,,}$ close to the inner and outer edges of the pole pieces (Figs. 1 and 8), there are useful currents inducted also in them in such directions that they will correspond with those inducted in $P_{,} P_{,,}$. In the position (Fig. 17) the molecular currents between the south and north poles are of such a direction that they flow away from the part $R_{,}$ while the latter is moving towards the right-hand side; this inducts, according to the laws

Fig. 19.

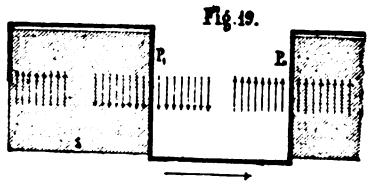

Fig. 20.

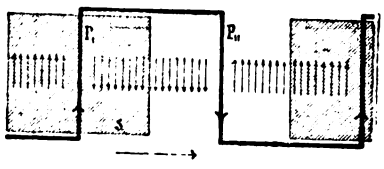

of induction in $R_{,}$, a current of equal direction with the motion of the latter and corresponding with that inducted in $P_{,}$ and $P_{,,}$. The same is the case in the part $R_{,,}$ and in all other parts $R_{,} R_{,,}$ belonging to the same circuit. When the disc has advanced $\frac{1}{16}$th of a revolution, the molecular currents flow everywhere *towards* $R_{,} R_{,,}$, which inducts a current in an opposite sense to the motion of the latter, corresponding again to the radial inductions then taking place. In the same way, induction takes place in those parts, $R_{,,}$, which pass, as in Fig. 12, towards the left hand side,

The commutator (Fig. 4) consists of eight rings, L, combined in pairs for each circuit, well insulated from each other. Each ring has eight projections, and they are put together so that the sixteen projections of each pair are exactly $\frac{1}{16}$th of a circle apart.

The sixty-four projections form the sections of the commutator, against which the positive and negative brushes are so adjusted that they touch simultaneously the projections of a pair of the rings. The contact surfaces of the brushes may therefore be 1, 3, 5 . . . . . to 15 sixteenths of the circle apart from each other.

The connections of the circuits with the commutator may be arranged in different ways. For currents of low tension each circuit may be led directly to the commutator, which connects it with the external circuit so long as its potential is higher than that of the main current, and cuts it out so long as the potential is lower. To secure a good action, the potential must be equal to that of the main current at the moment when the brushes make or break contact with the sections of the commutator, and to accomplish this the brushes are made in pairs, which can be adjusted so as to cover more or less of the sections of the rings. Two, and at some moments three, of the four armature circuits are at the same time connected to the external circuit. In this case it is of advantage to construct the pole pieces broad, as appears in Fig. 17. If a higher tension is desired, then the pole pieces should be narrow, so as to concentrate the field.

The circuits may also be combined in one single endless one, and branches taken from it to the commutator, according to the system Gramme. In this case the disc should be divided into more than four circuits, which may be accomplished by the arrangement shown in Fig. 7B, which contains seven separate circuits, each of which may be again divided into two, by transposing the magnets in the circle accordingly. The pole pieces should then also be made narrow, and fewer magnets be used (say 10 or 12 pairs), in order that the neutral places may be wider, to prevent sparks at the commutator.

To remove the shaft B with the armature easily, the stands E E are open at *e e'*. These openings are closed by segments, to which two or more magnets are fastened, and which are removed with the segment, if the shaft is to be lifted out.

AN ELECTRICAL VALVE.—This apparatus is designed to regulate the supply of heat to a room by the temperature of the room itself, and consists of a thermostat, on the principle of differential expansion, which can be set at any desired temperature at any time by anyone by means of a small set screw—an "electro-pneumatic valve," which is an ordinary electro-magnet of 6 ohms resistance, and which has attached to its armature a stem operating a tiny pneumatic valve. This valve, though perfectly double acting, has a play of only 1-32 of an inch. The apparatus is really worked by compressed air, which is forced into a tank 12in. in diameter and 15ft. long, by means of an automatic air-pump driven by water pressure, only consuming from five to ten gallons of water daily. This compressed air is led by means of common $\frac{1}{8}$in. brass tubing to every room in the house connected with the inlet of the electro-pneumatic valve in that room. Now, as long as the temperature in the room is lower than the thermostat is set, the circuit is open and steam is allowed to enter the coils. But the instant the temperature rises one-fourth of 1° over this point the circuit is closed, the electro-pneumatic valve is opened, and the compressed air allowed to flow into a diaphragm steam valve in the radiator, and the valve is seated by a positive piston motion and held in its seat by a force of from 100 to 150 pounds. This continues till the temperature falls one-fourth of 1°, when the circuit is broken, the electro-pneumatic valve closes against the compressed air reservoir and opens a vent for the air in the diaphragm valve, which, escaping, allows the valve to open and admit steam till again checked by a rise in the temperature as before. This system seems to remove the greatest objection to steam-heating.—*Electrical World*.

ELECTRICAL PROGRESS.

The completion of another Half-Year's Volume of *The Electrician* offers a fitting occasion for reviewing the progress that has been made in electrical enterprise since last November. It may as well be confessed at once that the hopes with which we ended our previous volume have not been realised to the extent we had hoped, or electrical engineers had expected. But, perhaps, on that very account it may be useful to survey our present position and prospects.

As to the latter, the confidence which prevailed in 1884 remains unshaken. It is only in the matter of immediate and substantial results that there have been some disappointments. First, and chiefly, nothing has come of the efforts made to amend the Electric Lighting Act; though these efforts have no doubt had some effect in paving the way for the desired alterations, or for the abolition of the Act when a more convenient season shall arrive. Besides the important committee, which went thoroughly into the question and presented its Report, several influential bodies have petitioned the Board of Trade with a similar object; and, what is more, the extended sphere of electric lighting enterprise is steadily operating in the same direction.

Foremost amongst the agencies for promoting this object is, of course, the grand and varied displays of Electric Lighting at the Inventories Exhibition, some notion of the magnitude of which may be gathered from our Exhibition Supplement, which we propose to continue during the season. We shall give full details of the various exhibits interesting to our readers, as circumstances permit; but already we are glad to notify a general improvement in respect to some defects which we have formerly called attention to. Until recently there was a tendency among makers of Dynamos and Engines employed in electric lighting to fall into a groove of what may be called regulation patterns and sizes, just as though we could always count upon splitting up the work to be done into equal portions proportionate to the power "in stock," or could use it with economy where the power is in excess of the work to be done. Engines and dynamos should be ordered to suit the occasion, just as is the case with all other kinds of engineering. Of course there will always be regulation sizes in demand; but special conditions are so numerous and various that both engineers and makers should lay themselves out for designing and making exactly the kind and power of machinery required for the special work in hand, whether large or small, whether arc lighting or incandescent, or both.

Considerable business has been done in fitting with the Electric Light the ships of our mercantile marine; and this is a business sure to go on expanding. A very brisk demand has arisen in this department in consequence of the expected outbreak of hostilities, a great number of men-of-war having been fitted not only with the ordinary lighting arrangements, but with special appliances adapted for the purposes of warfare. It is now almost certain that the interpretation put upon these appliances by their makers will not be submitted to the arbitration of any impartial shell, foreign or native. But although the experiment would have been highly instructive, we cannot, perhaps, on other grounds, regret that it is not to be tried just at present. The lighting of a portion of the navy, however, remains a fact, and one which we expect to see largely extended.

Of independent installations on land, differing in this respect from the miscellaneous ones at the Exhibition, the most important is that at the Paddington Station and Hotel, to be completed, we believe, next month. Its results will be watched with keen interest by everybody interested in the practical and financial success of Electric Lighting on a somewhat unusual scale.

Turning to another branch of electrical industry, we have had a Parliamentary Committee taking evidence relating to overhead wires in the metropolis. The result of this inquiry is at present highly problematical, the interests concerned in maintaining these wires being extremely powerful, and the testimony in support of them so inaccurate, that we apprehend the worst, especially as the evidence on the other side, although conclusive enough, is half-hearted and comparatively small in bulk. Should, however, the Report recommend the laying of the wires underground it will be impossible to repeat in this country the farce that is being played in New York. Physicians of that city have been feed to certify that the opening up of the pavements would very likely give rise to an epidemic of cholera. As London streets are always in a chronic state of dissolution, either Londoners are impervious to cholera or there is no cholera in the composition of London pavement. We may thank the New York telephone companies for this lesson.

The Submarine Cable Protection Bill, which passed the House of Commons on Tuesday last, will throw a moral as well as a legal obstacle in the way of cable destroyers. It is something to have got the fact recognised that to wantonly, or even carelessly, disable a submarine cable is an offence against international law, and is punishable like any other aggression upon private property. Submarine Cable business is, on the

Digitized by Google

whole, not in the most flourishing condition just now; for although the traffic consequent upon warlike operations—whether they be actual war or not—is very considerable, it hardly makes up for the loss of commercial traffic which these operations create. The public who are invited to find money for fresh cables should bear this fact in mind. No cable company, however advantageously situated, prefers a period of disturbance and war to one of peaceful and active trading; and this is not the time to project new submarine lines, unless for national purposes, and paid for by the nation. The system of coding, too, which has become quite a science among cable customers, has altered the conditions under which cable owners invested their money. Every fresh year's experience shows that the basis on which the tariffs were framed is not a remunerative one, now that the character of the traffic has undergone a complete change.

Down to the time of our going to press there was still some uncertainty as to whether the Postmaster-General's Bill for the introduction of sixpenny telegrams will be allowed to pass this Session. The threatened opposition to its abolishing the free addresses has grown into something rather formidable; but if Mr. Lefevre holds to his threat to withdraw the Bill if this provision is rejected, probably the objectors may be silenced.

CORRESPONDENCE.

PROF. FORBES' REPORT ON THE B.T.K. BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is extremely doubtful whether the Consolidated Electric Company have in any way advanced the merits of their B.T.K. storage battery by publishing Prof. Forbes' report of the tests he carried out with them, as it seems to be anything but satisfactory as regards their efficiency.

To commence with, the master cell seems only to act properly when a *certain rate of charge* is employed. Now, the present demand for secondary batteries is mainly, if not entirely, required for the lighting of private residences, either to overcome the unsteadiness of the motive power, or to have a store of electricity for possible night use after the engine has been stopped; and as the number of lights is continually altering, the rate of charge is proportionately increasing and decreasing, which will in its turn affect seriously, if not fatally, the proper working of the master cell. I have assumed in this case that the dynamo is running whilst the majority of lights are being used, this being the only true economical method of employing accumulators. Thus the master cell may be looked upon as not a success.

Then, as to the figures given of the charges and discharges, they are both scientifically and practically worthless, as there is absolutely no data whatever given as to the rate of either charge or discharge, the only item given being that the E.M.F. had fallen very low indeed; which at once stamps the two columns of figures as of no value whatever, as who would think of calling the discharge or "output" of a battery "useful" after the E.M.F. had fallen 18 per cent., though it may have fallen even lower than this? As Prof. Forbes says, "I discharged until the E.M.F. had fallen more than would have been convenient in practice;" and subsequently says that he considers a fall of 18 per cent. allowable. I think that only a fall, at the very outside, of 7 or 8 per cent. should be allowed in calculating the true commercial efficiency of a battery; so that the efficiency given as 60·23 per cent. should read something like 25 per cent. if the real facts of the case were known. Some designation, too, might have been given to these two interesting columns of figures, instead of leaving it to the imagination of the reader. I take it for granted that the figures given under the fifth discharge are accidentally inaccurate, otherwise the cells seem to have given out 70 per cent. more than was put into them at this stage, and this when corrected further very materially reduces Prof. Forbes' statement of the *true* commercial efficiency.

His next statement, that some of the cells lost their E.M.F. entirely, thus causing the efficiency of the battery to be lower than would otherwise have been the case, is worthy of attention, as he distinctly states that the only way to test batteries properly is by taking a number of cells in series, and not singly, so that his results must be taken as indicating what the battery is capable of doing in practice, and nobody wants to know what they should do, had they all remained in a theoretically perfect condition.

Prof. Forbes then goes on to say that some of the plates bulged; but this would not have been the case had the plates been properly used. Are we to understand, then, that he did not treat them fairly whilst testing them? Though this can hardly be the case, seeing that the rate of charge or discharge was strictly in accordance with what the Company themselves preferred to use, and they would hardly have given any other than that which gave the best results. I think that the bulging simply showed itself in the ordinary course of the working of the cells, and is anything but unusual with secondary batteries, this defect being one that has caused more trouble than all the other shortcomings put together, and it always will appear unless some special arrangement is made for preventing it. As to the test with the new set of cells, the same remarks apply to it also as regards the "practical output" being calculated by allowing the E.M.F. to fall *only* 14 per cent.

In conclusion, it would be satisfactory to learn for whose benefit the report has been so extensively published in its present form, whether for electricians or the general public. If it is for the former it is of no use whatever, as it gives no information that would be of service in determining whether or no the batteries could be relied upon in practice; though certainly, to judge from the opening paragraphs, it did give promise of being an accurate and detailed report, if we notice the careful way in which it is stated how accurately the measuring instruments were continually calibrated. But if it is meant for the general public it is more likely to frighten than inspire them with confidence in secondary batteries.—Yours, &c.,

F. GEERE HOWARD.

May 5, 1885.

THE INVENTORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you kindly allow me to correct a statement appearing in your issue of last Saturday regarding our exhibits at the Inventions Exhibition.

The Prince of Wales's Pavilion is not lighted by Swan lamps, nor from a dynamo (directly), nor is the dynamo driven by an Elwell-Parker high-speed engine.

We are using Woodhouse and Rawson lamps, which are fed from our accumulators arranged on the north side of the pavilion. These are charged by one of our dynamos in the daytime.

Our high-speed engine is used in connection with Mr. Holroyd Smith's electric tramway, and in our train-lighting plant shown at the Coalbrookdale Company's exhibit.—Yours, &c.,

P. BEDFORD ELWELL, Director,
For Elwell-Parker (Limited).

ELECTRICAL CONDITION v. RECENT SCIENCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It has been said on unquestionable authority that the word "energy" is of recent introduction into science, and we are now commonly told of "heat energy" and "electrical energy;" but my conviction is that no one is able clearly to define the meaning of energy as a scientific definition. It certainly will not stand the test of reasoning. Another word to which I am a stranger is "potential." "The difference of potential between two metals when in contact." But what can it mean? In 1847, as may be seen on reference to any chemical work of that or previous date, the zinc of the galvanic battery was positive and the copper negative. But in

Digitized by Google

one of a series of papers I wrote in the *Chemist* from April to October, 1847, consecutively, I suggested that the plates when taken out of the battery indicated the condition of their respective atmospheres, which must be in an opposite condition to that of the plates themselves—that the zinc, in fact, was actually undergoing combustion, and must therefore be negative. It is true that science was deplorably led astray on the heat doctrine, but I do not remember an instance in which recourse was had to the possible in support of an argument.

In the several pages of this journal reference is made to "the electric light," as if electricity were the cause of light; and when I have seen a flash of lightning leave a cloud and illumine the atmosphere for miles around, I have been under the impression that it proceeded from electricity accumulated in the cloud. But in a review of a lecture delivered by Sir W. Thomson on the same theory, it is said "We have one of the best attempts to give a popular explanation of the wave theory of light since Prof. Tyndall delivered his course of lectures on light in the United States." To me the theory is utterly incomprehensible, and appears to be based on the assumption of an agent the presence of which has to be demonstrated, its performances actually bordering on the miraculous, as the following extracts will show :—

"Sir W. Thomson speaks of 400 million million, and says that some people told him they could not understand a million million, when he replied they could not understand that two and two make four. To him finitude is incomprehensible, while the infinite in the universe is comprehensible, for we cannot conceive an end of matter or an end of space. We can understand 1,000 per second as easily as we can one per second; and as there is no finitude, it is not impossible to conceive 400 billion vibrations per second; and when the luminiferous ether vibrates at that rate, the normal human eye perceives red light."

Now, one per second is naturally less than a healthy pulsation, but to count a thousand beats per second is, so far as I can comprehend, an impossible; and what relation there is between there being no finitude and the 400 billion vibrations of the luminiferous ether quite surpasses my comprehension.

"To move one's hand once per second requires but a very moderate force; to move it ten times in a second requires 100 times as much force, and for 100 vibrations per second 100,000 times as much force. Similarly, to move anything 400 billion times a second, a force would be required one billion billion times as great."

As Sir W. Thomson said, consider greatly what that number means, and what we are to infer from it. What force is there in space between the eye and the light? What forces are there between the eye and the sun or Sirius? There is matter and there is motion; but what magnitude of force may there be? "The luminiferous ether is the only substance," says Sir W. Thomson, "we are confident of in dynamics, and through that we can move as if it were nothing." We are then told that the luminiferous ether, according to Sir W. Thomson, is an elastic solid, and the nearest analogy he could find was to compare it to a bowl of jelly, with a little ball of wood floating in the middle, by means of which he imparted vibration to the jelly. He also compared it to shoemakers' wax, a large slab of which he placed in water with corks attached to the under surface, and bullets on the top. After dilating on what Sir W. Thomson believes, that the discoveries in electricity, the motions of comets, and the marvellous sparks of light from them, tend to show cracks in the luminiferous ether—that is, shows a correspondence between the electric flash and the aurora borealis, and cracks in the luminiferous ether—we are told that, "what is certain is the existence of an all-pervading medium, an elastic solid, with a great degree of rigidity, the rigidity being so great in proportion to its diversity that the vibrations of light have the frequency above mentioned." In no one instance, however, does Sir W. Thomson adduce a fact corroborative of this wave doctrine of light, nor of the existence of the luminiferous ether.

Professor Tyndall in "Heat a Mode of Motion," like Sir W. Thomson, speculates on the undefinable, and tells us that the heat developed by the stoppage of the earth in its orbit would be equal to that derived from the combustion of fourteen globes of coal, each equal to the earth in magnitude; and if after stoppage it fell into the sun, the heat would be equal to that of the combustion of 5,600 worlds of solid carbon. But, to pass from the improbable to the matter of fact, it is said that solid carbonic acid is cold enough to *burn the hand*, and that a piece of iron of equal coldness would do serious damage. Why cold "burns" does not appear, the fact being totally opposed to the heat doctrine; but on the principle of electrical condition, as explained in my letter at page 455, the effect is produced by the combination of the oxygen and hydrogen of the flesh to the production of water, the electricity of both the acid and iron being in excess, or free. It is then demonstrated that if the solid acid be placed on the thick portions of ordinary tumblers or drinking glasses, and the acid be wetted with ether, the glasses are shattered by "the contraction produced by the intense cold;" whereas I contend that the effect is produced by evolution of free electricity, which electricity would travel through a wire to a hot solution, which cold—that is, the normal cold of a body—will not do." In this basin I spread a little paper, and over the paper I pour a pound or two of mercury; on the mercury I place some solid carbonic acid, and on the acid I pour a little ether. Mercury, you know, requires a very low temperature to freeze it; well, here it is frozen."

Connected with frozen mercury there are two facts that demand consideration. In the northern, but more especially the Polar regions, the mercury of thermometers freezes, and the temperature of the atmosphere is assumed to be equally cold. But if the bulb of a thermometer be moistened with ether, or even with strong spirits of wine, the temperature decreases with each application; and on the exposure of a thermometer to a very cold atmosphere it gradually descends to the freezing point of the mercury, and that is assumed to be the actual temperature of the air. I have suggested, on the evidence of facts, that a vacuum is highly electrical—may, in fact, be a representative of space. It is not improbable, then, that in the freezing of the mercury of the bulbs of the thermometers the vacuum may be an important factor; and I am not aware of any experiment having been made with two thermometer bulbs—one a vacuum and the other not. In the above detailed experiment of the freezing of "a pound or two" of mercury with *some* solid carbonic acid moistened with ether no cognisance is taken of relative proportions.

All the above facts have a direct bearing on the cause of intense cold, and if a lump of frozen mercury be placed in front of one of a pair of mirrors, it is said that a delicate thermometer in the focus of the other gives evidence of heat; in reference to which fact M. Pauillit avers that the thawing mercury actually gives out heat. A red hot cannon ball, similarly placed, we know will ignite tinder in the focus of the second mirror, and this action is assigned to the heat given out by the red hot ball. But heat has an expanding influence on air, and the ascending air could not otherwise than prevent any of it reaching the second mirror. If, however, we assume the incandescent iron to be surrounded by an atmosphere electrical in proportion to the incandescence, the electricity would readily travel to the mirror, and, by producing in the focus a high electrical atmosphere round the tinder, cause ignition, as the free electricity given off from the thawing mercury produces the apparent influence of heat on the thermometer, which, I presume, is not a mercurial one.

On a previous occasion I have stated that during combustion hydrogen has a much greater affinity for oxygen than carbon has, and this principle is most beautifully illustrated in the production of artificial light, whether from a candle, gas, or mineral oil. In contemplating a candle we see round and above the wick a bluish translucent cone, above which and around it is an incandescent opaque mass or cone producing the light, and this without doubt is surrounded by an electrical medium, proportional to the incandescence. But Professor Tyndall, in the work already referred to, avers that the bluish flame, like burning hydrogen, and its surroundings are "unburnt vapour within, common air without, whilst between both is a shell which forms the battle ground of the clashing atoms, where they develop their light and heat," which light

Digitized by Google

and heat to be developed must be in the materials in a latent state. The chemical action of course goes for nothing.

On a *red hot* silver basin being placed on hot water, the basin does not touch the water but maintains a space underneath, the fact being accounted for because "the basin for a time develops a sufficient amount of vapour underneath it to lift it entirely out of contact with the water; or, in the language of the hypothesis developed in our third picture, it is lifted by the discharge of molecular projectiles against the under surface." But what causes the molecular projectiles does not appear; the red hot basin and its electrical atmosphere being clearly the factor. If, however, the basin be reversed and made hot by placing the spirit lamp underneath it, "every drop, as it strikes the hot surface, and as it rolls along the surface, develops vapour, which lifts it out of contact, thus destroying all cohesion between the surface and the drop, and enabling the latter to preserve its spherical or spheroidal form;" but on this heat doctrine the vapour should dissipate the drop. On the leaves of many plants, but more especially the blades of grass and of wheat, the drop of dew retains its spherical form without being lifted out of contact, a fact to which my attention was forcibly directed in 1853, when having passed through a piece of potatoes dry footed, on entering a piece of grass my stockings became sopped. I therefore retraced my steps, and then found that the potato leaf absorbed the moisture, whilst the grass did not, but without doubt evolved electricity.

At page 212 of this work there is detailed a very beautiful experiment, consisting of an incandescent lamp, acted upon by a galvanic battery through a coil of wire, having in the middle of it two feet of platinum wire, which necessarily becomes red hot; and the wire in so becoming red hot deadens the light. But on its being bent and plunged into a basin of water, the lamp increases in splendour proportionally to the immersion of the platinum wire. Does, then, the water alter the nature of the wire, or does it become a conductor of the fluid? On the circuit being broken by the fusion of the two feet of wire, *when surrounded by air*, the lamp, as a matter of course, went out.

In the next page the question is asked, "Are we to suppose the cold to be an entity?" and it is answered in the negative, "No." But from the time of putting the question to the present, electricity has been gradually growing to an "agent" and a "fluid," to, of course, the validity of the cold doctrine, and exclusion of the heat ones. And a platinum wire is fused by a current, when surrounded by air, but becomes a good conductor when surrounded by water!—Yours, &c.,

FRANKLIN COXWORTHY,
Author of "Electrical Condition" of 1848.

PROFESSOR TYNDALL ON THE SOURCES OF ELECTRICITY.

The fifth lecture was delivered on the 6th of January. At the outset, Professor Tyndall said that some years ago he endeavoured to put in the smallest possible compass a quantity of knowledge regarding electricity, and the work was published by Messrs. Longman. Those gentlemen had been liberal enough to allow him to have 500 copies of this little *brochure* on very moderate terms; but, as he had the honour of speaking to an audience of more than 500, he had thought it better to wait until the last lecture in order to keep them all on the same level, and then distribute them all at the same time. On the next occasion, therefore, some of them would be able to take away with them a little reminder of what they had heard during the lectures. Resuming his lecture, he said that he had placed before them a series of electric cells and an electric battery—that was, single cells and a battery devised by his friend Sir William Grove. Calling attention to a plate of platinum and a plate of zinc, he said that they were immersed in liquid. If they examined the screw which he indicated, they would find positive electricity on one side and negative electricity on the other; and, if he united one screw to the other, they would have a flow of electricity from screw to screw, the positive flowing in one direction and the negative in the other. They agreed to call (and he wished them to understand that it was a mere arbitrary agreement to do so) the direction in which the positive electricity moved the direction of the current. Uniting screw to screw by a wire or conductor, he stated that there was a current of electricity flowing from one side to the other. Mr. Cotterell had placed there a piece of platinum wire, and he would connect this wire to this cell. Passing on from this point he called their attention to a single cell, which he said at that moment had no power. There was a platinum wire, and a current was flowing there through a thin platinum wire that spanned the space from wire to wire, but the current coming from the single cell was too feeble to raise the wire to incandescence. Directing their attention to a battery, which he described as a collection of cells, he stated that exactly as in the case of the Leyden jar they had the single Leyden jar and the battery of Leyden jars, so now they had the single cell and the battery of cells. If they examined the five cells before him in a proper electroscope they would find the strength of electricity (at points indicated) exactly five times the strength of the single cell. He would now show them a battery of ten cells. They would find the force with which the electricity tended to burst from the cell was in direct ratio with the number of cells. Now, Mr. Cotterell would show them that this ten-cell battery had power to produce effects very much greater than the single cell. Mr. Cotterell would make the connection, and they would see that what the single cell could not do the ten cells did, and they saw the wire in a state of incandescence [experiment]. They had a battery downstairs with fifty of these cells, and he wanted to direct their attention now to a point of very great importance in connection with the flow of the electric current. If the electric current encountered no resistance in its passage they could have no heat. It was because the platinum wire refused to allow the current to pass through—because there was a conflict between that and the current—that the conflict produced the incandescence. If he placed another wire there they would see no heat at all, because in a wire producing no heat there would be little or no resistance, and hence the philosophy of the electric conductor. They saw these conductors on churches and other buildings. If the discharge struck a chimney without a conductor the chimney was shattered. He now showed them a rather long wire, and pointed out that it was red hot. He wanted to show them, in these experiments with regard to the point of resistance, that the current rose up, so to say, an enemy in its own path. If he chilled a portion of the wire when the current was passing through, a greater amount of electricity would flow through the chilled portion, and that greater amount ought to raise the remaining portion of the wire—the portion unchilled—to a higher state of incandescence. [Experiment showing this.] Electric light and electric heat were very powerful elements, the most powerful they could command. Mr. Cotterell would now give him a pair of carbon points. Carbon was a substance first used by Davy in that institution to obtain his great electric light. He had his two thousand pair of plates, and he produced with this a light four inches long. As the battery before them augmented in its number of cells the electricity became sharper and sharper. The most sensitive boy present could not feel anything from a single cell, but coming up to fifty the heat was rather sharp, particularly if one's fingers were wet. With five hundred cells they approached more and more to the electricity of the machine. The greater number of cells they added to the battery the more they approached the electricity of the machine. Exhibiting a wire, he said he would now show them the wondrous electric light that was shown in 1810 by Davy with his two thousand plates. [Experiment.] If he brought the two wires together under the water they would see the effect. [Experiment.] He would now ask Mr. Cotterell to put a steel file to one of the poles connected to one of the wires. He held now a steel file; he had one of the carbon points and brought them together, showing the power produced by the current. He described this as a beautiful experiment, the file being utterly dissipated in a shower of sparks. He now wished to hark back for a short time to a point illustrated rather fully in the last lecture—the subject of electro-chemistry. He would take two plates of platinum which were perfectly free out of the blue liquid before him, which was a solution of sulphate of copper. He would ask Mr. Cotterell to make a contact [experiment], and they would see that the wondrous electric current had torn the copper from its combination, and the copper was deposited on the surface of the liquid. The two plates were now no longer the plates they were when they were put in the liquid. If he now made use of the two plates he obtained virtually two metals, one copper, and one platinum. If he connected the two together he would get a strong current of electricity, from the one to the other, and in all cases where that occurred the current that flowed through these newly-created metals was always in an opposite direction to that which had produced the precipitation of the metal. All our electric accumulators, as they were called, depended simply upon this principle. They must not imagine that electricity was a thing to be obtained stored up in boxes as water was. The accumulator depended upon the principle they had just seen elucidated. They took two pieces of lead, and here Planté took the first great step, and communicated it to the Academy of Paris, and that had been improved upon by

Digitized by Google

Faure and Sellon. The two currents were utilised to a great degree. [Experiment.] What he wanted them to understand was the principle of the thing. They took a number of cells—and, instead of platinum, pieces of lead—and they sent a current through those cells from an external source. The plates of lead were altered so as to make them different from each other, and they were converted virtually into two metals. This secondary battery could then be used to produce electricity. He was told that the battery (exhibited) had been used several times on the Thames on boats. Displaying a smaller one, he said it was intended to be carried in the pocket, and the jet of light produced was meant for a breast pin. He understood that similar batteries were employed by ladies on the stage to produce a light as a sort of ornament in their hair. Before quitting the subject of electro-chemistry there was one point he would mention, a point brought forward and emphasised very strongly by Faraday. They had seen the powerful battery which had been exhibited there. Faraday operated on the battery, and many a time he (the lecturer) had himself used it. They saw that an electric current had the power of deflecting a needle, and Faraday sent a current from the battery into a magnetic needle. He took two very thin wires, one platinum and the other zinc, one-thirteenth of an inch in diameter. He dipped these wires in acidulated water, the depth of immersion being only five-eighths of an inch, and he allowed them to be there one-seventh of a second, and during that time those two wires produced a greater effect than the machine of 28 tons which they saw in the previous lecture.

They must now go further into the relationship between electricity and magnetism. In 1820 the deflection of the magnetic needle was noticed by Oersted, of Copenhagen, and an account of the investigation was given of that in Geneva, and thence it went to the Academy of Sciences, in Paris. There was at that time in Paris a great scientific man, and a man of wonderful character corresponding with his greatness of intellect—Ampère; and in a single week he laid the foundation of what was called electro-magnetism. One new discovery by Ampère was that electric currents flowing in the same direction attracted each other, and electric currents flowing in another direction repelled each other. Calling attention to what he described as "an arrangement of the kind," the lecturer displayed a bent wire; and, dipping one wire into a cup of mercury, and another dipped into a little cup containing mercury, he said if they connected the two cups the currents would flow to and fro in opposite directions. [Experiment.] If he simply turned his hand and reversed the direction of the current, they had a repulsion. The currents were now flowing in an opposite direction, and, if he turned it upside down, they ought to have attraction. They could see it, though it was very feeble. He had suspended two spirals of wire through which he could send a current, and the stronger the current the better. Mr. Cotterell would connect the wires from the spirals to the instrument indicated, which was called the current reverser. He wanted to show them that the principle of attraction and repulsion was also manifested. He could send a current through these two wires which would flow in the same direction to the coil. When that was so, the ends of the coil would go thus together. [Experiment.] By reversing the current they had attraction and repulsion. [Experiments.] He wanted to show them next that they could get magnetic action, as Ampère had shown, without any magnet whatever. [Experiment.] He wanted to get two spirals into the circuit. [Experiment.] The motion they saw was due to the action of the earth's magnetism on that spiral. He would reverse the current, reverse the polarity—and he would not be surprised if it came back again. He would reverse the current and stop the motion towards him. They had another spiral, and if he brought it to one end of the coil they had repulsion. In that way Ampère imitated by means of electric currents all the actions of a magnet. He would now give them one or two more experiments in connection with the relationship of electricity and magnetism. The matter was gone into after Ampère's time by other scientific men, and they came to the conclusion that they must be able to obtain rotation—rotation around the current and rotation around the magnet. Faraday wrote an article on the electro-magnet. In doing so he had to read all that Ampère had written, and he became so impressed with the idea that he could get rotation that he tried and succeeded in obtaining rotation round a magnet and rotation round a current. [Experiment.] Mr. Cotterell would throw the shadow on the screen, and they would see the motion. The moment he made the connection they would observe the rotation. They could now see the magnet rotating around the current, and by reversing the current the motion would be stopped and would go in an opposite direction, and they now saw a rotation of the current around the magnet. There were various other experiments which he might show them connected with the relationship of electricity to magnetism; but he would now pass on and come to one of the other sources of electricity. He had before him some instruments which would enable him to illustrate this other source of electricity. It was discovered by Seebeck, of Berlin, he believed, in 1826. He held, as they could see, two metals soldered together. One was bismuth and the other antimony. In front of him was the magnetic needle. He would act on that magnetic needle, and make it their tell-tale as to the existence of an electric current. Connecting the bismuth and antimony with the needle, he stated that an electric current was produced by contact at the junction of the bismuth and the antimony, which would make itself evident on the needle. [Experiment.] There they had a new source of electricity. He wanted to make a battery of a pile, and he united the bismuth and antimony rods together. If they wanted to augment the strength of the action they united the rods together, and then they had a thermopile. He connected it, as before, with the galvanometer. If he simply touched this pile with his finger they would see its extreme sensitiveness. [Experiment]. Mr. Cotterell wished to bring the needle to zero, but as long as one place was warmer than another there would be an electric current. [Experiment.] It crossed to zero, and went up to 90 degrees on the other side. Calling their attention to a reflector, he observed that he had devoted some ten or twelve years of his life working at this thermo-electric pile. They saw its extreme sensitiveness. It was at first presented by an Italian savant, and afterwards worked at by an illustrious Italian named Melloni. The instrument before them was Melloni's thermopile, and the reflector which he (the lecturer) had placed on it was silvered within for the purpose of concentrating on the face of the pile very feeble radiation of heat. He might say that this thermo-electric pile was mainly due to investigations on radiant heat. The young gentleman who had been experimented on before would now assist him, and they would see, if his cheek were warm, what the effect would be on the pile. [Experiment.] His cheek was warm, and the pile was going up. Taking a piece of ice, he said they would see what occurred through the agency of a cold body instead of a hot. The needle would come down. [Experiment.] The needle would pass over the zero line, and would go up the other side. There was a very great man at the beginning of this century who founded that institution, Count Rumford. He was led to believe that there were rays of cold just as well as rays of heat, and he figured to his mind the rays of cold passing through and chilling the pile. The pile became a warm body in comparison with the ice; the heat absorbed the ice, and in that way the pile became chilled and they got action due to the chilling. It was always very necessary to augment the delicacy of their instruments; and that was done with regard to the electric current by the galvanometer of Sir William Thomson. It was simply a suspended magnet. The one before them was small and it moved to and fro by that action. He had had presented to him a bismuth and copper plate, and if he heated one side of it they would see how the needle, which was between both, came out. [Experiment.] There was one experiment more he wanted to show them with crystal of tourmaline, which had been a source of perplexity and mystery to a great many. It was found that it possessed electric properties — properties like rubbed amber. It possessed the property of attracting light bodies. It required to be heated in order that its effect should be shown. He would now place the crystal into the flame of the spirit lamp. The perplexity arose from one person observing one effect and others other effects from the crystal. If he brought it to bear on the needle they would see that the needle was strongly attracted by it. What occurred was this:—In the investigation into the subject of this crystal of tourmaline it was found that sometimes one had at one end positive and sometimes at the other end positive, and the most diverse statements were made. When it came to a normal temperature there was no attraction, but when there was heat they had attraction, and they also had attraction while the heat was diminishing. This was a sample of what he called pyro-electricity. They had had, first, friction, then voltaic, next (that day) thermo, and now he had given them a sample of what he called pyro-electricity. He concluded by observing that he might go on showing them that the power they had just seen was possessed by other crystals besides crystals of tourmaline.

ON THE CHANGES PRODUCED BY MAGNETISATION IN THE LENGTH OF RODS OF IRON, STEEL, AND NICKEL.*

BY SHELFORD BIDWELL, M.A., LL.B.

The earliest systematic experiments on the effects produced by magnetisation upon the length of iron and steel bars are those of Joule, an account of which is published in the *Phil. Mag.* of 1847. Joule's experiments have many times been repeated, and his general results confirmed. In particular, Prof. A. M. Mayer carried out a series of very careful observations with apparatus of elaborate construction and great delicacy. The conclusions at which he arrived were in accord with those of Joule, so far as regards iron. In the case of steel there was some apparent discre-

* Abstract of a Paper read at the Royal Society, April 23.

Digitized by Google

pancy, which, however, might to a great extent be accounted for by differences in the quality of the metal used, and in the manner of conducting the experiments. In 1882 Prof. Barrett published in *Nature* an account of some experiments which he had made, not only on iron, but also on bars of nickel and cobalt, with the view of ascertaining the effect of magnetisation upon their length.

The knowledge on the subject up to the present time may be summarisd as follows :—

1. Magnetisation causes in iron bars an elongation, the amount of which varies up to a certain point as the square of the magnetising force. When the saturation point is approached the elongation is less than this law would require. The effect is greater in proportion to the softness of the metal.

2. When a rod or wire of iron is stretched by a weight, the elongating effect of magnetisation is diminished ; and if the ratio of the weight to the section of the wire exceeds a certain limit, magnetisation causes retraction instead of elongation.

3. Soft steel behaves like iron, but the elongation for a given magnetising force is smaller (Joule). Hard steel is slightly elongated, both when the magnetising current is made and when it is interrupted, provided that the strength of the successive currents is gradually increased (Joule). The first application of the magnetising force causes elongation of a steel bar if it is tempered blue, and retraction if it is tempered yellow ; subsequent applications of the *same* external magnetising force cause temporary retraction, whether the temper of the steel is blue or yellow (Mayer).

4. The length of a nickel bar is diminished by magnetisation, the maximum retraction being twice as great as the maximum elongation of iron (Barrett).

In order that the results of Joule and Mayer might be comparable with those obtained by the author, he made an attempt to estimate the magnetising forces with which they worked. From data contained in their paper it was calculated that the strongest magnetising force used by Joule was about 126 units, while the strongest used by Mayer did not on the highest probable estimate exceed 118 units. In the author's experiments the magnetising force was carried up to about 312 units. The metal rods, too, were much smaller than any which had been before used for the purpose, ranging in diameter from 1·40 to 6·25 mm. Their length was in every case 100 mm., and the apparatus was capable of measuring with tolerable certainty an elongation or retraction equal to a ten-millionth part of this length.

By using thinner iron rods and greater magnetising forces than those previously employed, the following curious and interesting fact was established. If the magnetisation be carried beyond a certain critical point, the consequent elongation, instead of remaining stationary at a maximum, becomes diminished, the diminution increasing with the magnetising force. If the force is sufficiently increased, a point is arrived at where the original length of the rod is totally unaffected by magnetisation ; and if the magnetisation be carried still further, the original length of the rod will be reduced. It also appeared that the position of the critical point in steel depended in a very remarkable manner upon the hardness or temper of the metal ; considerable light is thus thrown on the apparently anomalous results obtained by Joule and by Mayer. Further experiments disclosed strong reason for believing that the value of the critical magnetising force in a thin iron rod was greatly reduced by stretching ; this would explain the fact that Joule obtained opposite effects with stretched and unstretched wires.

By ascertaining the relative values of the temporary moments induced by gradually increasing external magnetising forces, an attempt was made to connect the point of maximum elongation with a definite phase of the magnetisation of the several rods in which the elongation had been observed.

Though more experiments must be made before it is possible to generalise from them with perfect safety, the results so far obtained by the author indicate the laws given below. The elongations and magnetisations referred to are temporary only ; before the beginning of an experiment the rod was permanently magnetised by passing through the magnetising coil a current equal to the strongest subsequently used. In iron the greatest elongation due to permanent magnetisation was generally found to be about one-third of the total elongation, while in nickel the permanent retraction amounted only to about one twenty-fifth part of the whole.

I. *Iron.*

1. The length of an iron rod is increased by magnetisation up to a certain critical value of the magnetising force, when a maximum elongation is reached.

2. If the critical value of the magnetising force is exceeded, the elongation is diminished until with a sufficiently powerful magnetising force the original length of the rod is unaffected, and if the force is still further increased, the rod undergoes retraction. Shortly after the critical point is passed, the elongation diminishes in proportion as the magnetising force increases. The greatest actual retraction hitherto observed was equal to about half the maximum elongation, but there was no indication of a limit, and a stronger magnetising force would have produced further retraction.

3. The value of the external magnetising force corresponding to maximum elongation is for a given rod, approximately equal to twice its value at the "turning point."

Definition.—The turning point in the magnetisation of an iron bar is reached when the temporary moment begins to increase less rapidly than the external magnetising force.

4. The external force corresponding to the point of maximum elongation increases (when the quality of the iron is the same) with the diameter of the rod. So also does its value at the turning point.

5. The amount of the maximum elongation appears to vary inversely as the square root of the diameter of the rod, when the quality of the iron is the same.

6. The turning point, and therefore presumably the point of maximum elongation, occurs with a smaller magnetising force when the rod is stretched than when it is unstretched.

II. *Steel.*

7. In soft steel magnetisation produces elongation, which, as in the case of iron, increases up to a certain value of the magnetising force, and afterwards diminishes. The maximum elongation is less than in iron, and the rate of diminution after the maximum is passed is also less.

8. The critical value of the magnetising force for a steel rod diminishes with increasing hardness up to a certain point, corresponding to a yellow temper ; after which it increases, and with very hard steel becomes very high. There is therefore a critical degree of hardness for which the critical magnetising force is a minimum ; in steel of a yellow temper the value of the critical magnetising force is lower than in steel which is either softer or harder.

9. In soft steel a strong magnetising force subsequently diminished may cause a greater temporary elongation than the diminished force is capable of producing if applied in the first place.

10. A temporary elongation when once produced in soft steel may be maintained by a magnetising force which is itself too small to originate any perceptible elongation.

III. *Nickel.*

11. Nickel continues to retract with magnetising forces far exceeding those which produce the maximum elongation of iron. The greatest observed retraction of nickel is more than three times the maximum observed elongation of iron, and the limit has not yet been reached.

12. A nickel wire stretched by a weight undergoes retraction when magnetised.

PROGRESS IN SOUTH AUSTRALIA.

From a comprehensive report on the Post Office, Telegraph, and Observatory Departments of South Australia, by Charles Todd, C.M.G., F.R.A.S., Postmaster-General, Superintendent of Telegraphs, and Government Astronomer, which has recently been issued, we extract the following :—

The Telegraph Prior to 1870.

In December, 1855, the first Government telegraph line in the colony—Adelaide to Port Adelaide—was commenced, and on February, 1856, the line was opened for business, and was extended to Lefevre's Peninsula early in the succeeding month, the total cost, including erection of stations at the Port and semaphore, being £3,024.

The line was carried underground from the Port to the semaphore, and from the Adelaide Railway Station to the central office in King William-street. The underground cables consisted of six gutta percha double-coated copper wires, with an outer serving of tarred yarn, laid at a depth of two feet, in Henley's split pipes, a six-wire submarine cable (a remnant of the first Mediterranean cable) being laid under the river at the Port. Along the Port Railway the wires were overhead on square poles of Western Australian jarrah and Singapore cedar ; and it may be of interest to state that these poles are only now (1884) being taken up, having been replaced by much longer poles. The instruments selected were the Henley magnetic double needle, which were ultimately superseded by the Morse system, as the telegraph was extended to the other colonies.

It may be amusing to mention that the first day's receipts were 5s. 3d., the second 2s. 6d., the third 1s. 9d., and the fourth 1s. 3d.—totals certainly not calculated to inspire much confidence in the financial success of the infant scheme. It should, however, be stated that a rival line, erected by Mr. Jas. Macgeorge, had been opened between Adelaide and the Port immediately prior to the completion of the Government telegraph, and this secured for a time a large amount of public patronage. This line was ultimately purchased of Messrs. Elder, Stirling, and Co., for £80, and pulled down.

The business, however, steadily increased, and by the end of the year 14,738 messages had been transmitted, yielding a revenue of £366 6s. 7d.

A line of two wires to Gawler, including a branch to the Labour Prison, 28¼ miles, and costing £1,576, or a little over £55 per mile, was opened on April 14th, 1857 ; and that year there were 35,792 messages, yielding £1,183 13s. 10d., the receipts on the Port line being £883 17s. 2d.

In July, 1856, a scheme was submitted for an intercolonial line of telegraph between Melbourne and Adelaide, estimated to cost £20,500, and this amount being approved by the Government, the necessary provision was made on the Estimates for 1857. The actual cost of the line was £19,403 9s. ; it was commenced in April, 1857, and opened through to Melbourne on the 21st July, 1858. The route selected was *vid* Goolwa, and thence to Pelican Point, at the entrance to the Coorong, a submarine cable being laid across the Goolwa Channel and Lake Alexandrina. This cable gave much trouble, and was ultimately abandoned, the wire being taken by way of Strathalbyn and Wellington, after a second wire had been erected by that route in March, 1861.

At this time (1858) the telegraph had made only a beginning in New South Wales, a short line to the South Head being opened in January. Melbourne and Sydney were connected by telegraph on October 29, 1858, and Brisbane not until November, 1861. The telegraph was introduced into Tasmania

Digitized by Google

in 1859, and in the month of August that year a cable was laid across Bass Straits in four sections, viz. :—

From Parker River to Victoria Cove, King's Island	49 miles
From Sea Elephant Bay, King's Island, to Three Hummock Island	50 ,,
Three Hummock Island, to West Bay, Circular Head	25 ,,
Circular Head to Low Head, near the mouth of the Tamar	72 ,,
	196 ,,

with intermediate connecting land lines across King's Island, Three Hummock Island, and Circular Head. This cable had a very short life of a few weeks only ; and it was not until a second cable was laid from Cape Schank to Low Head, in May, 1869, that Tasmania was permanently connected with the telegraph system on the mainland.

The telegraph was introduced into the several colonies as under :—

Victoria.—March, 1854, line to Sandhurst and Williamstown.
South Australia.—February, 1856, and a few weeks earlier by Mr. Macgeorge's line to Port Adelaide.
New South Wales.—January, 1858, line to South Head.
Queensland.—April 10, 1861.
Tasmania.—August, 1859.
New Zealand.—July, 1865.
Western Australia.—June, 1869, a private line from Perth to Fremantle taken over by the Government in April, 1871.

At first there was but one intercolonial wire ; but in 1859 the pressure one this was so great that a second wire became a matter of immediate necessity. This was completed by the end of 1861, the duplicate wire taking the route *vid* Wellington ; and about the same time a second wire was also put up between Melbourne and Sydney.

It was not until 1st May, 1867, that through communication between Adelaide and Sydney was established by the erection of a direct line. Communication, however, between Adelaide and Wentworth had been effected since August, 1866.

In the meantime the telegraph in South Australia had been extended to Kapunda, Clare, Kooringa, the new mining centres at Kadina, Wallaroo, and Moonta, Port Augusta, and other places.

The number of offices in South Australia at the end of 1869 was 63 ; length of line, 1,113 miles ; length of wire, 1,642 miles ; and the expenditure on lines and instruments, &c., to December, 31st, 1869, amounted to £101,591 10s. 3d.

The post and telegraph departments were amalgamated on January 1st, 1870 ; and from that date have been dealt with as one department.

In regard to the revenue and expenditure, the following comparative statement will show the growth of the telegraphs during the period 1870-83 :—

Telegraph.	1870.	1883
Number of offices	73	179
Length of lines (miles)	1,183	5,161¼
Length of wires (miles)	1,718	8,293¼
Number of telegrams (Colonial and Intercolonial)	128,485	653,119
Receipts from ditto	£10,649 16s.	£42,603 11s. 7d.
Number of International telegrams	—	43,334
Value of ditto	—	£251,277 19s. 8d.
Receipts due to South Australia	—	£27,510 5s. 7d.
Total telegraph revenue	£10,517 14s. 3d.	£75,877 3s.

The Port Darwin line was opened for traffic on August 22nd, 1872 ; but cable communication was interrupted from June 23rd till October 21st, when through communication with England was established.

Of the several schemes for extending telegraphic communication to Australia, the first was that submitted by Mr. Francis Gisborne, who visited Australia in 1859. The promoters he represented proposed to lay a light cable from the east end of Java, in five sections, to Moreton Bay—3,780 knots, including slack, at an estimated cost of £800,000. The colonies were either to take over and work the cables themselves, or guarantee to supplement the net receipts up to 6 per cent. on the capital outlay. After considerable negotiations, the Victorian Legislature passed resolutions in 1860, agreeing, under certain conditions, to a subsidy limited to £13,000 ; and New South Wales similarly agreed to a subsidy of £9,625.

The cable was to be of the same type, but rather heavier, than that first laid in the Red Sea, or, rather, between Suez and Bombay ; but that cable, like the first laid under the Atlantic, soon came to grief ; and, as a matter of fact, although the negotiations were continued by Mr. Gisborne and his co-promoters for several years, nothing was done.

In 1862 a prospectus was issued by the promoters of the Anglo-Australian and China Telegraph for a system of cables to connect Rangoon, Singapore, and Hong Kong, Java, and Moreton Bay, at an estimated cost of £2,080,000. The Australian Colonies were asked to guarantee a subsidy of £50,000 per annum for thirty years.

In March, 1870, a letter, dated 22nd June, addressed to the Governor, was received from Admiral Sherard Osborn, R.N., managing director of the Telegraph Construction and Maintenance Company, enclosing a prospectus of the British-Australian Telegraph Company, and stating that his company had received orders from the latter to manufacture a cable and construct a land line to connect Singapore and Burketown, the then proposed terminus of the Queensland telegraph system ; but as a portion of such land line from Port Darwin, where the cable was to be landed, would pass through the northern territory, Commander Noel Osborne, R.N., as agent for the company, was to be sent out to seek the sanction of the South Australian Government for the execution of these works. In reply the company were informed that, whilst every facility would be afforded to Commander Osborn, the Government would much prefer the construction of a telegraph line from Port Darwin to Port Augusta, then our most northern station, and that, with this view, they were prepared to submit to the Legislature a measure to authorise the entering into an agreement with the company for a direct line across the continent to Port Darwin, to be erected either by the company, under a Government guarantee, or constructed and worked by the Government.

It was finally determined that the Government should undertake the construction of the line to Port Darwin, to be completed by 1st of January, 1872, and the company agreed to lay and complete by the same date a cable from Singapore to Batavia, and from Banjoewangie to Port Darwin, the two sections to be connected by an intermediate land line through Java, to be constructed by the Government of Netherlands India.

A Bill was accordingly introduced and passed, authorising a preliminary loan of £120,000 for the land line.

The Government further undertook to provide a site for the cable company's office and quarters for staff at Palmerston, and agreed to erect the buildings at the expense of the company.

The following is a table of the distances in miles of the sea and land lines now connecting Australia with England :—

Falmouth to Gibraltar, *vid* Lisbon (sea)	1,250
Gibraltar to Malta (sea)	981
Malta to Alexandria (sea)	819
Alexandria to Suez (land line)	224
Suez to Aden (sea)	1,308
Aden to Bombay (sea)	1,664
Bombay to Madras (land)	600
Madras to Penang (sea)	1,213
Penang to Singapore (sea)	381
Singapore to Batavia (sea)	560
Batavia to Banjoewangie (land)	480
Banjoewangie to Port Darwin	970
Port Darwin to Adelaide, S.A. (land)	1,975
Total	12,425
Total length of cable	9,146
Total length of land lines	3,279
Total	12,425

ROYAL COLONIAL INSTITUTE.

At a recent meeting of the Royal Colonial Institute a paper was read by the Hon. Mr. Justice Pinsent, D.C.L., on "Newfoundland," from which we extract the following :—

"I am here reminded of the debt in reference to oceanic telegraphy which the world owes to our modest and (except when required as an inevitable necessity) neglected colony. The germ of the system of ocean telegraphy which now connects the whole civilised world is found in the legislation of Newfoundland, in the intelligent and more than generous encouragement extended to those early movements from which the now world-wide system took its rise. The first project, regarded from the view of later achievements, was a very modest one. It designed to reduce the period of communication between Europe and America by two or three days, by erecting a line of telegraph across the Island of Newfoundland, connected with a short submarine cable to Cape Breton. To this end the Newfoundland Electric Telegraph Company was, at the instance of Mr. F. N. Gisborne, its projector, established in 1852, under charter from the Newfoundland Legislature. This company was succeeded by the New York, Newfoundland, and London Telegraph Company, also incorporated by the Legislature of Newfoundland (subsidised with land grants and money guarantees), which took up the work, and associated with it the idea of an Atlantic cable. This last idea was not realised in fact for some years. In the meantime Newfoundland was the great Transatlantic telegraph post, with headquarters at St. John's, and it became the habit of the mail steamships to call off Cape Race, and then despatch and receive the latest news. Just at the fitting time, and as if the finger of Providence were in it, a United States Naval Expedition in 1853 surveyed the Atlantic bed. The result was to give strength and stimulus to the idea of an ocean cable. Commander Berryman reported thus : 'This line of sea sounding seems to be decisive of the question as to the practicability of a submarine telegraph between the two continents, *in so far as the sea is concerned.* From Newfoundland to Ireland the bottom of the sea is a plateau, which seems to have been placed there specially for the purpose of holding the wires of a submarine telegraph and keeping them out of harm's way.' The report went on to describe the facts more fully, and in them has been found to be the superiority which time ever keeps testing of the Anglo-American and its associated companies' systems over all others. Matter-of-course a thing as ocean telegraphic communication now is, the history of its early difficulties and disasters, and its ultimate triumph when in 1866 the 'Great Eastern' seemed to fulfil her destiny in successfully laying the fourth attempted cable, is a thrilling one, and every man should read it who would learn what intelligent perseverance and indomitable energy are capable of doing in the cause of humanity. To me as a Newfoundlander, who was present at the consummation of this work at Heart's Content, Newfoundland (the only Newfoundlander, indeed, who boarded the 'Great Eastern' as she steamed up Trinity Bay), the memory of the day is one of the most gratifying

Digitized by Google

recollections of my life, the more especially as the colony was so honourably associated with this the grandest project of modern times, one which has produced a revolution of the most important kind in commerce and human intercourse—and one which would have been long, and might have been indefinitely retarded but for the liberal and ready aid the colony accorded it. I need hardly observe that by means of the Atlantic cable St. John's enjoys telegraphic communication with all parts of the world ; and I may add that, locally speaking, there is a system of telegraphy most completely connecting the capital with all the principal and numerous smaller settlements, and these with each other, all around the coast."

LEGAL:

Dawson v. The Phœnix Electric Light Company.

This was an action recently brought before Mr. Justice Chitty by Mr. Charles Dawson to set aside a contract under which he took 500 shares in the defendant company; also to recover £250 paid by him in respect thereto, with interest at 5 per cent., from the company and the directors of the company, on the ground that the contract was induced by misrepresentation in the prospectus and fraud.

Mr. ROMER, in opening the case for the plaintiff, said the company was registered on the 16th of May, 1882, and the defendants were the first directors of the company. The auditors were Messrs. Foster, Hight, and Co., and there was an arrangement between them and Mr. Byers, the promoter of the company, which was subsequently ratified by the company, that they should get a commission of 1s. a share for placing the shares for the company ; also that they should have a call of 10,000 shares for a period of seven days, commencing from the 22nd of May. A prospectus was prepared for the company (by whom it did not clearly appear), which was adopted by and issued on behalf of the directors on the 23rd May. The plaintiff received a prospectus and circular shortly after the 25th of May, and thereupon applied for 500 shares, which number was allotted to him on the 1st of June, he paying 5s. a share on them, making £125, and on the 5th July, 1882, a further call of 5s. a share, which made up the £250 in all. In the beginning of July the plaintiff began to suspect the bona fides of the company, and wrote inquiring into its position, but could get no information. He therefore obtained inspection, and then ascertained the alleged misrepresentations in the prospectus, and on the 19th of July the present action was brought. The company had since been wound up. The prospectus said that the company had received offers for the purchase of a concession in England for £40,000, and proposals amounting to £145,000 in other districts. Now, he would tell his lordship what was the alleged justification for the statement as to the offer of £40,000. In the minute book there was an entry as to the proceedings of a Board meeting held on the 22nd May : "The following letters were read and ordered to be entered in the minute book." Among those letters there was one, dated the 15th of May, addressed to Messrs. Byers and Company (the promoters), 54, New Broad-street, from P. Arthur and Co., of 13, Walbrook, in which Messrs. P. Arthur and Co. said that they were willing to enter into an arrangement with them to purchase the sole exclusive rights of their (the company's) patents for the lamps and dynamo machines for the North of England for the sum of £40,000, part in cash and part in shares of a company, provided such company went to allotment. That was really no offer at all, as Mr. P. Arthur rented a garret for four hours each day at the top of a very small house in Walbrook, simply having the right to go there and write his letters. The directors made no inquiry as to Mr. P. Arthur, but yet seemed rather to have doubted the bona fides of the offer, for on the 22nd of May the secretary, Mr. Walter Dunlop, wrote saying the directors entertained the offer, but required a deposit of £1,000, to be lodged with the company's bankers before 2 p.m. on Wednesday, the 24th inst. No answer was received to that letter, and therefore on the 24th the directors knew the character of the offer of £40,000, and yet proceeded to allotment on the 1st of June on the faith of the statements in the prospectus. The £145,000 offer came from a firm of the name of Messrs. Wilkes Brothers, 25, Change-Alley, E.C., who were a very small firm. The directors on the same 22nd May sent a similar letter to that written to P. Arthur and Co. He need scarcely say that nothing came of it. Lastly, there was a letter from a Mr. Prince as to the purchase of concessions, he being "authorised by influential friends." At that time Mr. Prince called himself a patent agent. The result of their inquiry was that they had found out that he had been insolvent six times between the years 1840 and 1868. The directors wrote him a similar letter requiring £1,000 as a deposit, to which, of course, there was no answer. Another statement in the prospectus was that Prof. Varley had said that in his opinion the lamp was superior to all existing incandescent lamps, and he thought that it might be found more durable than any yet known. That statement must have had weight. He found the way Prof. Varley himself expressed himself was as follows :— "I have examined the invention, and though I have not had an opportunity of submitting it to a test of long duration, am of opinion it is superior to any incandescent lamps existing." That was a qualified statement, and somewhat different to the one in the prospectus. Then there was a statement that the company had obtained the power to procure FitzGerald's patents. These patents were a lamp and a dynamo machine, but there turned out to be merely an agreement to purchase one of these. On the 9th May there was an agreement between Jones and Henry, by which Jones sold Henry the patent for £20,000, £4,000 in cash and the rest in shares. Four days aftewards Henry sells it to Waters for £35,000, £15,000 cash, £20,000 shares. Two days after that Waters sells it to the trustees of the company for £70,000, £30,000 in cash and £40,000 in shares. He had one more statement to complain of in the prospectus, viz., that application would be made to the Stock Exchange for an official quotation. His lordship was aware that by the rules of the Stock Exchange, in order to obtain an official quotation, two-thirds of the capital issued had to be applied for and allotted to the public. The nominal capital being £250,000 that would make 83,000 (one pound) shares. The directors, however, proceeded to allotment on 13,686 shares, and no more, for which they received £3,415, with the knowledge that under an agreement of the 9th of June they had immediately to pay the promoters £5,000. In those circumstances the learned counsel submitted that the plaintiff was clearly entitled to recover, the only answer the directors could give being that they really took no trouble in the matter.

Mr. CHAS. DAWSON, the plaintiff, stated that he was induced to purchase the shares by the statements in the prospectus that the company had purchased the FitzGerald patents (both lamp and dynamo), and that they had arranged for the sale of concessions. Paid great attention to the words quoted from Mr. Varley's report. Did not remember having seen Mr. Varley's original report. Applied for the shares on the 24th May. About the time electrical shares were rising fast in value. Had he been told the company had not acquired the patents, but only agreed to purchase them, should not have bought the shares. The paragraph as to the Stock Exchange quotation led him to think that £125,000 worth of shares had been applied for. The prospectus certainly did not say that.

Other evidence having been called bearing out counsel's statement, the plaintiff's case closed.

Mr. WHITEHORN, on behalf of Mr. Garland and Captain Revett, said he might say in the first place that the two directors for whom he appeared were honest persons, who had paid for their shares in the first place, and had not parted with them, neither were they promoters. The prospectus was approved at a Board meeting, held on 22nd May, which was the very one at which they were appointed directors. There was a difference between the directors who prepared the prospectus and those who, though their names appeared on the prospectus, had only become directors after the prospectus had been drawn up.

Further evidence having been taken for the defence, Mr. Justice CHITTY delivered judgment on Wednesday last. He held that the plaintiff failed with regard to the Stock Exchange statement, as it was only a statement of intention to apply to the Stock Exchange; and that he also failed as to the statement with regard to the purchase of the patents. Another and more serious ground was the statement than an offer had been received to purchase the workings of the patents in Scotland for £40,000. To decide this point it was necessary to look at the letters which made the offers, and examining the terms of these he saw nothing inconsistent with the terms of the offers in the statements in the prospectus. Another important point was the statement that "several good offers" had been made. One of the offers had been made by persons calling themselves "P. Arthur and Co.," who were to pay, but did not pay, twelve guineas a year for part of the use of a top room at 13, Walbrook, and these persons could not be found. Another offer came from a man named Prince, who had been twice bankrupt, and had 24 county court judgments against him, and who could not be found. On this ground the plaintiff was entitled as against the company to be relieved of the contract. Then, as to relief against the directors. All four of them were honest men, who had invested their money in the concern, and believed it was sound. The utmost that could be said against them was that they were careless ; but it appeared that they had made inquiries before they joined the company as to the substantiality of the persons who formed it. He thought the case failed as against the directors, but as against the company the plaintiff succeeded, and must be relieved of his contract. The plaintiff would prove in the liquidation of the company for the money paid by him as deposit and calls, and would have his costs.

Mr. ROMER asked if the plaintiff had a right to prove for the money paid with interest at 5 per cent.

Mr. Justice CHITTY acquiesced.

COMPANIES' MEETINGS & REPORTS.

Brazilian Submarine Telegraph Company.

The twenty-third ordinary general meeting of the shareholders in the above Company was held on the 7th inst., at the Cannon-street Hotel, under the presidency of the Right Hon. Viscount Monck.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting and the minutes of the last meeting. The report of the Directors (which has appeared in *The Electrician*) was taken as read.

The CHAIRMAN observed that at the late Royal Academy banquet several of the speakers bewailed their condition in that they were called upon every year to speak on the same subject, and found it very difficult to produce new matter for the entertainment of the company. He himself felt in a somewhat similar condition, for he appeared before the shareholders every six months to give an account of the transactions of the Company. Those transactions were generally of a monotonous, though he would not say of an altogether uninteresting description, because hitherto, as the shareholders had evinced by their reception on several occasions of the accounts, they were of a very prosperous undertaking. However, when the facts of the case did not

Digitized by Google

supply him with straw to assist him in the manufacture of his oratorical bricks, he honestly confessed that he found it rather difficult to make chaff take its place. As to the working of the past half year, he had very often said that it would not be fair to compare two succeeding half years as to revenue, because fluctuations of trade, upon which their revenue depended, caused a much larger income to be received very often in one half of the year than in the other half. Such a comparison would therefore be both fallacious and misleading. The breaking down of the cable in 1883 caused a breach in their receipts which would render a comparison with last year quite impossible and absurd; and he would therefore compare the half year, ending December last with the half year ending December, 1882. Making that comparison, he found that the income of the half year under review had been £817 more than in the earlier period—an increase which was not large, but still, it was an increase, and, taken in connection with the fact that there had been in the meantime a reduction in the tariff, it showed that they need fear nothing with regard to the increase in their trade. Their expenditure stood on a different footing to the revenue, because there was nothing in the circumstances of the case which ought necessarily to make any difference between the amount of the expenditure in the two half years. He found, then, that in the June half of 1884 the net expenditure had been £12,108, and in the December half of 1884 it had been £12,351. These figures had been arrived at by eleminating from the accounts the extraordinary expenses. There had thus been an increase of £243 in the expenses of the past half year as compared with the previous six months, but in that amount was included a payment of £72 for the use of patents. The fluctuation in this item was attributable to the fact that they only paid for the patents when they used them, and their cable having been down in a portion of 1884, the payments on account of patents were so much less in the previous year. The remaining portion of the increase had arisen from small increases of salaries, &c., in London and at the stations. As a company became older the *employés* expected an improvement to be made in their condition, and, beyond that, as the traffic increased, more hands were required. He could, however, assure them that the great object of the Directors—consistently, of course, with securing efficiency of work—was to make the expenses of the Company as small as possible. There was another matter connected with the expenses which he desired to bring before them. They would see on referring to the balance-sheet that £30,000 was due for their new cable to the Telegraph Construction and Maintenance Company at the time of the publication of the report. That amount, he was glad to say, had since been paid, and the cable was now the shareholders' own property, with the exception of the debentures, which he hoped they would pay off in time. Their property was in good condition; they were working well; their revenue showed a slight increase; and he trusted that nothing would occur to prevent their paying the dividends which they had hitherto been able to give. He concluded by moving the adoption of the report and accounts.

The VICE-CHAIRMAN (Sir James Anderson), in seconding the motion, observed, with reference to what the Chairman had said as to the small growth of revenue, that on the previous day he had realised another circumstance to account for this. He found that the Eastern Company were now carrying 100,000 more messages a year, with no more words, and that the Direct Spanish Company were really now carrying three messages for the money which they used to have for carrying one. This was owing to the word-rate and the methods of codifying which the merchants had arrived at, in a manner which he did not think was quite fair, because many of the codes were distinctly illegal. He thought it gratifying, in these circumstances, that this Company stood as well as it did in regard to its revenue.

The CHAIRMAN then put the motion, which was at once unanimously adopted, without discussion; and the proceedings closed with a vote of thanks to the Chairman and Directors.

London-Platino-Brazilian Telegraph Company (Limited).

Report of the Directors for the twelve months ended 31st March :—

The net revenue of the year, after providing for debenture interest and income-tax, is £5,943. 1s. 5d., and £1,005. 4s. 3d. is brought from the preceding year's account, making a total of £6,948. 5s. 8d. to the credit of the revenue account. The interim dividend of 1s. 3d. per share, paid on the 17th November, 1884, absorbed £2,396. 15s., leaving to be dealt with £4,551. 10s. 8d., from which the Directors propose to appropriate £150 in reduction of the item of expenses of issue of the 6 per cent. debentures, and £3,355. 9s. in payment of a final dividend of 1s. 9d. per share, being with the interim dividend at the rate of 1½ per cent. per annum, carrying forward a balance of £1,046. 1s. 8d. The Directors are pleased to remark the increase of traffic over the land lines in Uruguay, the net revenue from this source being £625 more than in the previous year. This increase, however, is more than counterbalanced by the serious decline in the amount received from the Western and Brazilian Company, the amount credited to this Company by that company being £10,655. 4s. 7d., against £12,638. 1s. 9d. in 1884. The difference between the Directors of this Company and the Western and Brazilian Company with respect to this Company's proportion of the receipts for telegrams, referred to in the last report issued by the Board, has not yet been disposed of; meanwhile the amount involved has been kept out of the accounts. The Board are able to congratulate the shareholders on the payment of the arrears of the Government Debt by the Uruguayan Government. As this debt, however, was paid in Bonds at par, their realisation necessarily entailed a loss; but, having regard to all circumstances, the Directors are glad that payment has been effected. It is satisfactory to find that the Government continue to pay for their current message accounts, and it is hoped that such arrears may be avoided in future. The Company's lines are in good working order. According to the Articles of Association, Francis Pavy, Esq., a Director of the Company, retires by rotation, and offers himself for re-election.
